PREFACE

Manfred SCHRENK,

Conference Director,
President CORP – Competence Center of Urban and Regional Planning

WELCOME to REAL CORP 2021, the
26th International Conference on Urban & Regional Development and Spatial Planning in the Information Society!

Urbanisation of the world is progressing rapidly and seems to be an unstoppable process. According to current forecasts, more than 6 billion people will live in cities in 2050. Compared to 1950, this is almost a tenfold increase in 100 years, resulting from global population growth and the continuing influx of people into urban areas. As a rule, population growth also means additional land requirements. Urban growth often takes place across administrative borders, cities grow into their surrounding areas, (cross-border) urban and metropolitan regions emerge and also influence the development of rural areas, where in turn numerous initiatives for independent sustainable development emerge.

This dynamic development is accompanied by enormous challenges for the organisation and maintenance of urban processes, particularly in the areas of technical and social infrastructure, affordable housing, mobility, recreation, security of supply, etc. Sustainability, resilience and smartness are essential characteristics of cities and regions and are often compared by means of benchmarks. The key question is how quality of life can be maintained and improved in the face of dynamic development of living space.

Even though the world is currently under the spell of the COVID-19 pandemic, it is clear that climate and environmental issues will be decisive for urban development in the coming decades. Climate adaptation strategies will play a central role, because especially in cities, high density, increasing land sealing, lack of greenery and inadequate ventilation increasingly lead to the formation of urban heat islands and the problem of urban warming.

How can urban and spatial planning and all related disciplines contribute to maintaining urban flows, functioning infrastructure and preserving and improving the quality of life? How can urban and rural living spaces actively cross-fertilise each other's development?

The REAL CORP 2021 call for papers was very broad and invited for contributions from all areas of expertise dealing with cities, regions and spatial development to gain a holistic and multi-faceted view on challenges and future scenarios in the urban realm. Next to science-based contributions we also asked for practise-based reports on short term actions and/or long-term strategies on urban and regional development.

This year's conference also featured some special topics in close co-operation with the respective partners mentioned:

- New Social Housing – Urban Climate Adaptation Strategies and Affordability of Life: How can that work? (partner: IBA Vienna)
- EU Mission: Climate Neutral and Smart Cities (partners: BMK, AustriaTech)
- Integrated Spatial and Energy Planning (partner: IRUB/BOKU)
- Cross-Border Spatial Development (partner: RWTH Aachen)
- Emergencies, Disasters, Epidemics – and the Big One: Pandemics (coordination: Judith Ryser)
- Sustainable Urbanisation Global Initiative: Food-Water-Energy Nexus (partners: BOKU, AIT, HFT – Stuttgart University of Applied Sciences)

And last but not least, REAL CORP 2021 was also host of the first ISCOCARP International Regional Event. Alongside to the annual world congress, ISOCARP is starting to experiment smaller-scale symposia which focus on issues of local importance, and which can be repeated on several occasions throughout the year in different regional and macro-regional contexts.

This year we brought together some 250 participants from more than 30 countries worldwide. The main goal of the REAL CORP conference series isto bring together leading experts in the field of spatial planning, geoinformation and related disciplines to exchange their knowledge, share their ideas, discuss current developments and get together for face to face networking leading to the development of new thoughts, partnerships and projects.

In times of a pandemic, this can be quite difficult, as travel warnings and other restrictions make the organisation of such an event very difficult and many decisions are based on uncertain forecasts. REAL CORP 2021 will take place as a hybrid conference: On the one hand, we have tried to welcome as many visitors as possible in Vienna in spite of all the restrictions, but on the other hand, it was also very important to us to make all the contents of the conference accessible to those participants who, for whatever reason, were not able to come to Vienna.

The success of the REAL CORP conferences is – clearly without doubt – the result of the efforts of participants, reviewers, and the conference organising team consisting of CORP association and the Institute of Spatial Planning, Environmental Planning and Land Rearrangement (IRUB) at the University f Natural Resources and Life Sciences. We would like to acknowledge the Reviewer Team and Programme Committee members for their valueable voluntary help with the review process.

Our thanks go to all participants and authors of the submitted papers as well. The proceedings of this year's conference contain around 130 scientific papers; more than 100 of them were selected after a double-blind, double-stage (for both abstracts and full papers) peer-review process for publication and presentation at the 26th International Conference on Urban Planning and Regional Development in the Information Society, REAL CORP 2021. The non-reviewed papers were accepted by the programme committee after a double-blind abstract review. The conference is held from 7 to 10 September 2021 in Vienna, Austria, as well as in virtual space.

Welcome to Vienna! Have a great conference!

Manfred SCHRENK, Clemens BEYER & the REAL CORP Team

Leonore GEWESSLER

Austrian Federal Minister for Climate Action, Environment, Energy, Mobility, Innovation and Technology

Dear honoured experts and planners!

I appreciate this profound pool of knowledge and expertise gathered in the course of this conference, which is more than welcome and urgently required to tackle our multi-dimensional challenges in sustainability and climate-neutrality whilst ensuring a high quality of life.

You as planning professionals and as planning community will have a key-role in the transformation of our society. High complexity and quick pace of change call for a new understanding of planning beyond traditional skills, tasks and singular disciplines. We need planners as visionaries, enablers for innovation, as intermediaries between different sectors and responsibilities, as coordinators and integrators, as advisors, but also as critical observers and sparing partners to challenge policy and administration.

I am sure that this conference can significantly contribute to the broadening of the knowledge and solution base, foster the exchange of experiences and will allow for joining forces and concerted actions in future planning in Austria and beyond.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Gernot STÖGLEHNER

Conference Host, Professor of Spatial Planning
Head of the Institute of Spatial Planning, Environmental Planning and Land Rearrangement
at BOKU Vienna

Dear Participants of REAL CORP 2021,

a warm welcome at BOKU University, either virtually or in real! We are in a time of disrutpions. The climate crises enters our daily lives. Storms, heavy rain, floodings, drought, heat, forest and bush fires, the news are full of such events, making the necessity of climate protection clear to everyone, but also mitigation must be planned.

At the same time we still are in the middle of a pandemia, and coping strategies open a window in a digital future. Digitalisation only starts with the broadband infrastructure, and will impose major changes to the ways we work and we organize our daily lives. In a study at my Institute we combined major studies about change in working procedures with the local labour markets on a municipality base. We found out, that up to 70% (!) of all work that now provides income to the people will be substituted by computers and machines.

Urban areas are a bit less hit by this transformation than rural areas, but on national average about 56% of all activities that provide income now might be substituted. This change is massive and can hopefully be utilized to create more jobs that consume less resources. And this transformation will change the way how we utilize space, whit major impacts on urban and regional planning. This transformation also offers opportunities to turn towards new planning solutions: CREATING HABITATS FOR THE 3RD MILLENNIUM SMART – SUSTAINABLE – CLIMATE NEUTRAL. Therefore, I wish the conference participants many interesting new insights, fruitful discussions, and I hope you have a good time in Vienna with new chances to meet people at CORP!

Welcome to Vienna!
Prof. Gernot Stöglehner and the whole IRUB/BOKU team

Hubert HASENAUER

Rector of BOKU Vienna, Professor of Forest Ecosystem Management

Dear Participants of REAL CORP 2021,

a warm welcome at the 26th REAL CORP, one of the major conferences in Europe on urban planning and regional development of our society. The University of Natural Resources and Life Sciences (BOKU) with about 2,900 faculty and staff members and 11,000 students, is strongly committed to sustainable development according to the UN sustainable development goals. In our research, teaching and third mission, we integrate sustainable development by managing natural resources and biodiversity as well as the environmental planning for cities and regions including their infrastructure.

With about 1,100 SCI publications annually and around 1,000 ongoing research projects, our research is well perceived within the scientific community and fundamental for our 7 bachelor, 27 master and 9 doctoral programsme. BOKU’s 15 departments cover all aspects of sustainable transition including the planning and design of living spaces; the production and utilization of (renewable) raw materials; technological, environmental, social and economic aspects up to impact assessment; the protection of biodiversity, soil, water, climate and landscape as well as resource recovery with respect to circular economy.

The conference topic “Creating habitats for the 3rd millennium – smart – sustainable – climate neutral” covers key BOKU competences in research, teaching and societal engagement. It fits perfect to one of the current key policy fields “Fit for 55” proposed by the European Union. I thank the organisers as well as the sponsors for making this meeting possible and wish all of you an inspiring conference with exciting days in Vienna.

With kind regards,
Univ.Prof. Dr. DDr.h.c. Hubert Hasenauer

A Prospective Approach for Cities in Transformation: Vision of the Leipzig Charter in the Light of the Covid-19 Experience

Judith Ryser, Teresa Franchini

(Arch. Judith Ryser, CityScope Europe, London, UK, judith@urbanthinker.com)
(Dr. Teresa Franchini, Temanova, Madrid, Spain, terefran@temanova.com)

1 ABSTRACT

Covid-19 acted as a trigger of an extreme situation that affected all aspects of life worldwide. Its effects on cities have been and are devastating. Covid-19 also revealed the lack of resolution of previous persistent urban problems and the reluctance of many governments to face up to short-term, politically unpopular solutions. Conversely, the pandemic has led to the emergence of trends whose effects could give rise to new sustainable urban dynamics in the medium and long term.

The paper explores how positive and negative changes of the built environment and its uses altered by the pandemic could be harnessed as lessons for sustainable post-Covid-19 urban development. It concentrates on identifying the main challenges of the Leipzig Charter's objectives - the "just, green and productive" city, pillars of sustainable urban development - to cope with the effects of worldwide calamities. The global and all-pervasive nature of the pandemic offers planners an opportunity to reflect on prospective scenarios that address truly resilient urban development.

Keywords: planning for the new normal, EU Leipzig charter, Covid-19 pandemic, scenarios, cities for the common good

2 PANDEMICS AND CITIES

2.1 Conceptual framework

The official recognition of sustainability as an objective at the Rio de Janeiro Summit in 1992 and of concern for climate change at the Tokyo Summit in 1997 were the milestones that directed universal action towards a collective objective, which was challenged in 2019 by the effects of Covid-19.

The uncertainty that characterises contemporary urban societies stems primarily from the combined effects of an unsustainable development model, a looming climate emergency and a pandemic that has revealed unresolved imbalances in cities. These three phenomena are interdependent and do not unfold in a vacuum. They are framed by the relentless exploitation of the planet, the political, administrative governance systems of nations, the current state of cities and their dynamics and also, critically, by human behaviour and underlying socio-cultural values that intertwine intrinsically in shaping unpredictability. The adaptation of contemporary societies to the effects of the pandemic depend to a large extent on collective as well as individual human behaviour which are shaping the direction of travel within an exceptionally turbulent context, giving rise to crucial conceptual questions.

Which directions of travel?

To-date and despite difficulties, the tri-partite economic, environmental and social nature of sustainability - although a rather elusive concept, possibly deliberately so - has been used for half a century to guide development policies around the world at global and local levels with varying results. The evolution of climate change and the urgency to act are well documented by scientific knowledge, observation and modelling. Now, the unexpected emergence of the pandemic deepens uncertainty about the planet and its inhabitants. All three phenomena are characterised by their universal nature. The urgency to act globally on the effects of the pandemic is testing the resilience of cities the effects of the health crisis on economic and political structures have taken priority at least for the time being over environmental and climate change initiatives, while redressing social inequalities inherited from the industrial era is again lagging behind.

Why is it so difficult to move in sustainable directions?

Corporate, collective and individual interests stand in the way of overcoming the obstacles that limit sustainable development, combating climate change and overcoming the effects of Covid-19. Governance has become more inclusive in many parts of the world, but the current global neo-liberal economic model remains dominant despite moves towards alternatives, such as the circular economy, the sharing or regenerative economy, collaborative consumption, co-working and consumer-production. At the local level,

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Transition Towns, Citta-Slow and the 15-minutes-city have pioneered some of these principles but such initiatives are few and remain fragmented.

Can a pandemic process be a turning point towards new breakthroughs?

Living in society means being in contact with viruses, parasites and bacteria. This cohabitation has produced recurrent epidemic and pandemic events whose effects have marked the fate of many cultures and civilisations throughout history.

It is said that the Athenian Plague (431-426 B.C.) put an end to the Athenian hegemony in the Peloponnese. The Antonine plague (165-180) affected the Western Roman Empire providing conditions for its decline but also the expansion of Christianity. The Plague of Justinian (541-750) affected the Byzantine Empire encouraging the decline of Antiquity and the spread of Islam. The Black Death (1347-1353) marked the end of the Middle Ages, the advent of the Renaissance and the economic power of Europe. The recurrent global epidemics of cholera (between 1817 and 1973) led to the birth of international medical cooperation. The Spanish Influenza (1918-1919/ 1920) contributed to the end of World War I, the discoveries of modern medicine and the advancement of public health. The Health Organisation was created in 1923, replaced by the World Health Organisation in 1948. The 20th and 21st centuries recorded the greatest number of global events: Asian Influenza (1957- 1958), Hong Kong Flu (1968), AIDS/HIV (1981-) SARS (2002-2003), Zika (2007-), Influenza A (2009-2010), Ebola (2014-2016) and now COVID- 19 (2020-). The search for vaccines led to accelerated activities of scientists and pharmaceutical companies and fostered greater international cooperation. This short historic overview shows the emergence of transforming socio-cultural and political changes once such tragic episodes were overcome. What will be the effects of COVID-19 on today's societies in the medium and long term? What new opportunities will they mean for cities?

2.2 An opportunity for urban planners?

The effects of the pandemic on cities offer a new approach for urban planners in the 21st century. The relationship between the physical environment, human behaviour and the governance of European cities challenges the principles proposed by the New Leipzig Charter (European Commission, 2020).

The paper focuses on physical-material changes necessary to make cities resilient. It refers to the recommendations of the New Leipzig Charter following a simple methodology:

- to discuss the aspects of the ‘just’, ‘green’ and ‘productive’ city proposed in the New Leipzig Charter using these issues as an analytical filter to detect the positive and negative aspects that emerged during the pandemic as a basis of future urban scenarios;
- to conjecture scenarios for the medium term - prospective visions for 2030
- as a means to promote the “power of transformation of cities for the common good”, the key concept of the New Leipzig Charter.

3 THE COMMON GOOD AND THE NEW NORMAL IN EUROPEAN CITIES

3.1 The scope of the New Leipzig Charter

The New Leipzig Charter - the Power of Transformation of Cities for the Common Good - approved in November 2020 by the ministers responsible for urban affairs of the EU promotes integrated and sustainable urban development in European cities, calling on the transformative powers of cities for the common good. The Charter responds to the demands of global agreements endorsed in 2007 by the first Leipzig Charter. Among them are the 2030 UN Programme for Sustainable Development (2015) and its New Urban Agenda (2017); the Paris Agreement under the UN Framework Convention on Climate Change (2016); the EU Urban Agenda (2016), the EU New Green Deal of the European Commission (2019), the EU Circular Economy Action Plan (2020) and the EU Territorial Agenda 2030 (2020).

The role of the New Leipzig Charter is particularly prominent in the Territorial Agenda 2030. The occurrence of the Covid-19 pandemic during the process of drafting the Territorial Agenda changed the outlook for Europe's future development, which recognises the importance of territorial cohesion in the recovery process, essential to increase the resilience of municipalities, regions and countries. The role of cities in this process is relevant and the New Leipzig Charter is the instrument that provides them with guidance on urban resilience in the face of global challenges, including pandemics. The principles of good governance and quality urban design are fundamental to ensuring attractive, inclusive, durable and adaptable places.

The New Leipzig Charter provides a roadmap for action to achieve fair, green and productive cities, with a site-based, multi-level and participatory approach. It aims to promote resilient and robust cities and urban systems to respond to disruptive events and chronic stresses, supported by nimble governance for the common good, underpinned by predictive and preventive policies, plans and projects including diverse scenarios to anticipate challenges of all kinds. This requires resources, finance, leadership and governance at all levels of government including key actors, both governmental and non-governmental.

3.2 What is expected of cities according to the Leipzig Charter?

According to the Leipzig Charter, the transformative power of cities is achieved by integrating the social, ecological and economic aspects of sustainable development which translates into 'just', 'green' and 'productive' cities: three cities in one.

The just city

The stated aim of the 'just city' is to provide equal opportunities and environmental justice regardless of gender, socio-economic status, age and origin, equal access to education, social services, health care and culture, energy supply and adequate, accessible, safe and affordable housing.

The green city

The "green city" is expected to contribute considerably to combating global warming by promoting polycentric, compact and dense multipurpose settlement structures with an adequate access to green and recreational spaces and efficient, carbon-neutral, safe and multi-modal transport and mobility systems.

The productive city

The "productive city" fosters the knowledge-based society and supports a diversified, digital, innovative and competitive economy, with a skilled, service-oriented and low-carbon workforce. It provides an innovative environment with attractive locations with social, technical and logistical infrastructures.

3.3 What is expected of the "new normal" in the post Covid-19 era?

The current "new normal" will remain in place at least until science reverses the spread of the virus or manages to eradicate it. The responses to the new normal in cities have been two-fold. Governance tended to concentrate on changing human behaviour ("hands, face, space": wash hands, keep social distance, stay at home) while physical adjustments took place at city level, in neighbourhoods and in homes, both spontaneously and planned. Most of them were temporary in response to Covid-19 government regulations, often in terms of emergency measures based on the latest scientific knowledge, aimed at curbing the spread of the pandemic, mainly to alleviate pressure on the health service, however with severe adverse impacts on the economy. What was hoped to be a short, sharp, shock has developed into a far longer term issue and is predicted to stay on in mutating form, akin to other virus diseases.

What aspects of the old normal will be permanent? What aspects of the Covid-19 situation will remain? What will the world be like after Covid-19? How will urban societies evolve? The proposed scenarios will address these questions.

3.4 How do "new normal" changes affect the sustainability principles?

The "New Urban Agenda" adopted at UN Habitat III in Quito in 2016 specifies the goals of sustainable development, inclusive urban economies and environmental protection for signatory governments to transpose into policies. Despite widespread consensus to reach such goals, there is hesitancy in implementing these measures. How can these goals be achieved if the general public lacks confidence in the responsiveness of their governments in charge of driving these changes forward and in the businesses which should spearhead a circular-plus economy leading to a more sustainable way of life of today's societies? The Covid-19 crisis has exposed the fragility of the dominant economic model and the lack of resilience both at global and local levels. It also shows that cities are ill prepared for future pandemics, potential energy crises, technological blackout and the biodiversity erosion.

4 IMPACTS OF COVID-19 ON THE THREE LEIPZIG CHARTER PILLARS

4.1 New effects or reinforcement of existing trends?

Covid-19 has added new trends to the "three types of cities in one" proposed in the New Leipzig Charter but, most importantly, brought to the fore existing inequalities and contradictions. The dominant economic model in Europe may provide some explanations: enhanced social divergence; government hesitancy towards social welfare; unequal access to healthcare and education; gender and ethnic inequity; and lack of genuine channels of participation for people to express their demands and achieve satisfaction. New effects are still in the making during the unpredictable evolution of the pandemic.

4.2 Just cities

Socio-cultural inequalities were a serious issue for cities before the pandemic but Covid-19 has made them more apparent and demands for a fairer society have become more vocal. Covid-19 has exacerbated political instability and accelerated uncertainty, reaching unprecedented levels of turbulence, growing populist nationalism and heightened fragility of liberal democracies.

In European neo-liberal market economies many parts of society are experiencing inadequate social wellbeing and welfare. Existing social-spatial polarisation, continuous shortage of affordable housing, weakness of the public health system, lack of adequate channels of participation to express their demand, and precarious employment or joblessness have increased more among the most deprived in society. So has domestic violence in vulnerable households. Women are carrying the brunt of the pandemic effects; burdened with even more unpaid work, child care and home education, they are also most at risk of job loss.

The young are likely to flout pandemic restrictions due to frustration and have the highest incidence of mental illness, while anti-social ideas of individual freedom are flourishing. Mental illness is also detected in older people, linked to loneliness, a structural problem in mature societies. Even in highly cosmopolitan cities, discrimination against minorities prevails, expressed in unequal service provision, poorer health conditions and lower life expectancy.

Regarding the justice system, the pandemic demonstrated the ineffectiveness of existing legislation to deal with high-risk situations, demonstrated by the need to adopt ad-hoc laws and the resistance to passing them in the parliamentary system.

4.3 Green cities

Covid-19 shifted awareness and concern for the environment and climate change towards maintaining public health. The shutdown of all activities and government instructions not to use public transport and travel by private car reduced air pollution to low levels during the early stage of the pandemic. Regrettably, this situation changed drastically during the de-escalation, reaching previous pollution levels across Europe. The need to maintain social distance has highlighted the difficulty for cities to accommodate travel by public transport and more walking and cycling were restricted by lack of safe space on streets and pavements.

The inherent inertia of the current often densely built up areas with sealed surfaces hampers the transformation of cities into a balanced green-blue-grey environment. The housing stock in cities is generally energy inefficient, with retrofitting measures scarce and poorly financed or subsidised. The lack of policies that resolve the dilemma of benefiting the owner-investor or the tenant is an issue that hampers energy adequacy of buildings. Public realm for social activities has proven scarce during the pandemic. High urban densities without adequate green space pose an insurmountable challenge, as transforming urban land for buildings into open space without real estate profitability contradicts the current economic system.

4.4 Productive cities

Hyper-globalisation underway before the pandemic may be countered by the need of countries to resort to local production of essential goods and services, or at least to reduce extreme dependency on global trade. After exceptional worldwide economic decline brought about by measures against Covid-19, economic recovery may take decades and progress only resume in a generation's time. Meanwhile, national debts may rise due to increasing interest rates and inflation, leading to austerity policies and cuts in public spending, even as welfare (especially health and infrastructure) may have to be strengthened to cope with future pandemics, notwithstanding the need to attenuate growing social-spatial inequalities to prevent social unrest.

Covid-19 has also brought to the fore latent changes in the world of work which may persist in post-Covid-19 organisation of business and working arrangements. Covid-19 accelerated the existing trend towards digitalisation: teleworking, robotics, artificial intelligence, automated services, telematics. This was already affecting the labour market and is likely to create new structural unemployment or underemployment in the longer term. The existing digital, spatial and social divide, the danger of excessive surveillance and risks to privacy protection have become more acute under the pandemic. The shift to homeworking is disadvantaging specific groups, and especially women who have to combine work with domestic activities and lower wages, as well as families with children affected by lack of computer equipment and technical skills, cost of broadband and inadequate space to work and study.

5 EMERGING CONTRADICTIONS

5.1 Covid-19 contradictions

Due to the urgency to act, the pandemic brought to the fore critical contradictions about the relation between competing interests. First among them is the contradiction about the relation between the economy and public health and how their mutual recoveries are seen either as oppositional or interdependent. While corporate interests and neo-liberal politics are contrasting economic recovery with overcoming the coronavirus and attributing priority to the economy over public health, science puts the right to material wellbeing on a par with the right to health. Scientists and environmental lobbyists consider humans as an inherent part of the global ecological system, in need of coping with existing realities, shaped by human behaviour and framed by continuous trade-offs. In their view the pandemic and the economy require integrated and hopefully synergetic solutions.

The pandemic has highlighted the complexity of human behaviour which, far from assuming a unitary response based on equality and solidarity, relies on emotions that contribute to the disruption of consensus. In the name of freedom, large segments of the population put individual rights before collective norms enacted to safeguard the common good by imposing spatial and functional lockdowns. Denial and anti-social behaviour, espoused by various groups including political parties, is reaching disturbing levels of intolerance.

The pandemic temporarily limited the fight against adverse climate change as it was unavoidable to take measures to address the health crisis, such as the production of plastics and non-reusable materials to avoid contagion. The new generation of waste associated with pandemic needs increased domestic energy demand, and the gradual return to global mobility of goods and people are challenging the GHG reduction targets.

Moreover, political responses to balance the demands made by economic and social sectors urging a return to the "old normal" have led to diverse types of measures, some of which difficult to reconcile with formal rule of law. The Covid-19 crisis has served as an excuse for many governments, at any level, to strengthen their power, potentially curtailing citizens' rights, the actions of domestic political oppositions and even intraregional or international cooperation. Most importantly, citizens do not trust governments.

5.2 "Three cities in one" contradictions

Similar contradictions can be identified between the three types of cities proposed in the Leipzig Charter, analysed in isolation instead of "in one". For example, economic growth philosophy (underlying the productive city) contradicts ecological capacity-bound resource consumption (defining the green city), while unfettered competition (driving the productive city) contradicts the collective common and mutual support of those most in need (motivating the just city). For the time being, the Covid-19 crisis has displaced the three pillars of sustainability expressed as productive, green and just cities. However, it provides the opportunity to reshape them to assist interdependent public health and economic recovery and, beyond that, to act upon the intrinsic links to climate urgency and adopt a broad understanding of social-spatial justice needed to underpin a genuinely sustainable city.

Not only are the "three types of cities in one" always treated separately without considering the overall structure of which the three pillars are an integral part, but the Leipzig Charter's vision does not take account of the political-administrative system and its pivotal role in achieving the common good of the sustainable city. Similarly, the Covid-19 effects on the three productive, green and just cities are analysed separately, without making the necessary connections between them which would uncover the contradictions inherent in

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

this tri-sectoral understanding of the 'sustainable city'. Some of their implied objectives may well be incompatible and the dichotomy between economic and public health recovery, a key debate of the political arena, is shining some light on this.

5.3 The missing fourth pillar: politics

The COVID-19 crisis illustrates the intersection between politics, economics, public health, environmental and social considerations. Although experts had warned of this potential pandemic, no government was adequately prepared to address this health threat. Investing time, money and political capital to tackle an abstract possibility is not part of the political agenda, as the focus on the next election reduces interest in funding policies with benefits beyond their term of office.

Responses to the crisis have varied across countries, depending on the interplay of relationships between different local interest groups, whether they are producers (industries, banks, corporations, trade unions) or consumers. Whatever the weight of these groups, the battle between interests of different nature is waged in the political arena which, in turn, decides the votes in elections in the short term and the survival of political parties in the long term. The policies adopted by governments to deal with the effects of COVID-19 have been strongly influenced by domestic pressures from the electorate, as well as by the action of international institutions (World Health Organisation, EU, OECD) in charge of coordinating a cooperative global response to the crisis.

5.4 A new model of thinking

A new model of thinking becomes necessary. It has to incorporate the political dimension of urban development as overarching all sectoral objectives and with the democratic mandate to establish a sustainable balance between all divisive interests. Such a model should incorporate the many innovative approaches to a more sustainable future promoted by enlightened business, ecological lobbies and social movements, as well as the political goals of achieving zero GHG emissions by 2050, a regenerative economy and social-spatial inclusion.

Once the pandemic is under control albeit not necessarily eliminated the other urgencies and how they have to be dealt with by urban development and change will need to be brought into mainstream policy and action again. The scenarios are imagining alternatives which may be able to respond to the new challenges brought about by the pandemic, the need for economic recovery and also for a more equitable society. At best society could resort to synergetic actions to achieve a better post-Covid 'new normal'; at worst adversarial human behaviour could undermine balanced economic, environmental and social recovery from Covid-19.

6 TOWARDS A DESIRABLE TRANSITION: TENTATIVE AND PROSPECTIVE MEASURES FOR POST-COVID CITIES

6.1 Opportunity for more people-led city powers?

Unprepared for Covid-19 cities responded with haphazard measures and governments imposed arbitrary restrictions on citizens, while people had to adjust to their externally determined situations with ad hoc reactions. Many of these spontaneous and often creative actions may well show the way to more permanent adjustments, although others may vanish as soon as the situation resorts to some normality.

While globalisation is trying to claim back its supremacy, nations are re-affirming greater sovereignty and mega-regions are demanding more devolution. Cities are also insisting on more autonomy and seize this unique opportunity of the pandemic to experiment with alternative productive, green and just models, aiming at smaller ecological footprints and more equitable deployment of human resources.

6.2 Towards a diversified economy in an innovative business environment

Despite global efforts towards sustainable development, the economy is bound to take priority in recovery and in shaping the post Covid future. For that reason, it may be necessary for a "new productive city" and its people to push for fundamental changes by resorting to alternative economic models, more conducive to generating sustainable development in an innovative business environment. Many such experiments have been tried already. There exists an extensive literature on alternative economic initiatives, too extensive to quote individually but succinctly referred to in the bibliography.

Such an alternative economic transition advocates an economy with a purpose, shifting from the unlimited growth ideology to an economy in which organisations identify their purpose and the impacts they want to generate in society aligned on the Agenda 2030 global goals. Alternative proposals have been designed for different levels and sectors: e.g. an economy for the common good; the "B Corps movement", fair trade, 'banking with values' or 'impact investments'; combined producer, consumer and user associations.

New alternative, more people-centred metrics have been developed to measure the success of the global economy and the performance of companies. Examples are OECD Better Life Index, UN Human Development Index, the New Economics Foundation Happy Planet Index or the Bhutan's Gross National Happiness Index for national economies, or the common good balance sheet or triple bottom line for business. In Europe, these measures intend to promote the JEDI concept - Justice, Equity, Diversity and Inclusion principles - and pledges to reach net zero carbon emissions by 2050.

These changes are supported by the Circular Economy principle, based on the concept of a "regenerative economy" that respects nature in order to mitigate the negative effects of climate change and the destruction of ecosystems. It is about achieving a resilient economy capable of achieving self-sufficiency at the local level with locally generated productive resources to face pandemic, energy or food crises. The new economy is also based on changes in consumer attitudes. "Consume less and better" has become a key concept, whereby. consumers can become producers or participate in collaborative consumption. Likewise, the Circular Economy blurs the boundaries between production and consumption into co-production, giving rise to collaborative consumption or "prosumption" networks, compounded by change of behaviour to reduce consumption and ecological footprint altogether and reinventing the worth of work. Advances in technology enable this cultural and lifestyle change. These economic considerations and many more are included in the targets of the European Green Deal to transform the EU´s economy into a sustainable future.

6.3 New planning and design principles to achieve a greener urban realm

The transition to the "new productive city" impacts also on the other two Leipzig pillars – the "green city" and the "just city" - which aim at zero pollution; preservation and restoration of ecosystems and biodiversity; fair, healthy and environmentally sound food production and consumption systems; sustainable and smart mobility, and 'leave no-one behind'. The financing of these objectives will support specific EU targets: maintaining the 2030 and 2050 climate goals; use of clean, affordable and secure energy; boosting the circular economy in industry; and encouraging construction and renovation using energy and resources in an efficient way.

The principles of sustainability and the climate change urgency had already prepared the ground for change to a more sustainable future and greener cities before the pandemic. Cities have already implemented many 'green' measures, physical, fiscal and behavioural. e.g. building insulation and retrofitting; congestion charging to curb motor traffic air pollution and congestion; shift from car use to public transport, cycling and walking and to electric vehicles and machines; waste recycling and reduction; reuse and repair of materials and products instead of discarding them; greening cities with trees, green walls and roofs; de-sealing surfaces; urban agriculture and more open space; and overall planning for greater resilience of buildings, neighbourhoods and cities. These measures to revert excess adverse climate change into ecological equilibrium and self-recovery will now have to be combined with measures to make cities more pandemic-resilient in the future as pandemic resilience is guided by the same ecological and sustainability principles.

Post-pandemic recovery is providing an opportunity to rethink sustainability criteria for cities comprehensively. This means taking into account the interdependence between productive, green and just city – the need to incorporate human health wellness, economic welfare and social wellbeing. Most important though is to obtain government support to realise change toward city sustainability. This also requires a step beyond a circular 'going-round' economy towards a sustainable 'spiralling-up economy based on primary resource sufficiency. Supported by political will these are achievable goals. An example is how the response to Covid-19 agreed in 2019 at EU and city level has strengthened the European New Green Deal.

6.4 From abstract promises to equal rights

The pandemic shed a new light on social relations, equal opportunities and environmental, spatial and social justice and main points to latent social change towards a just city. Public discourse moved identity politics

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

from social class to women, demographics, ethnic minorities, and gender. All these different identifications are influencing the notion of the just city. Pandemic lockdowns created new socio-economic divides and inequalities, affected by and affecting collective as well as individual human behaviour, albeit without a clear notion of how lasting these changes may be. An example is the enormous decline of mobility and its unequal effects. Staying at home meant less social contact, less travel for work or leisure by car, train or plane, but also a shift to virtual reality. The existing digital divide is affecting personal as well as professional communication and it remains an open question whether the necessary infrastructure to provide more equal access to digital communication, seen by many as a basic need akin to energy and water, will be forthcoming during or after Covid-19.

Overcoming the pandemic successfully means to compound constructive behavioural change towards it while coping simultaneously with climate change urgency and resource sufficiency. Most importantly, strong political will is required to curb the persistent dominance of the economy over ecology, sustainability and social-spatial justice. It also requires power of persuasion to gain cooperation from collectivities as well as individuals to change their habits. Conversely, communities and individuals can make an invaluable contribution to post-pandemic sustainable development. This would require resorting to genuine public participation, shifting from its lip-service position in planning to public engagement with real teeth, powers and responsibilities, including a share of material rewards resulting from improvements currently reserved to the development industry and the public sector alone. Citizens' voluntary actions should no longer be considered as free labour and information, but be rewarded according to its true economic as well as social and environmental value. This would mean enshrining effective powers, rightful roles and material awards for citizens into the development process of an integrated productive, green and just city.

7 PROSPECTIVE SCENARIOS FOR POST-COVID CITIES

7.1 Scenarios and their context

For 'Futuribles' (Hugues de Jouvenel) "the future is the domain of freedom, power and will", thus the usefulness of building 'prospective scenarios', of structuring reflections on the future in a situation of uncertainty. 'Foresight' explores possible scenarios to define desirable and doable futures. Scenarios can be beneficial during crises like the present pandemic and aim to provide long term assistance in terms of anticipation and action to the elaboration of public policies. For the OECD 'Foresight' can support government policy-making with better anticipation, policy innovation and future-proofing (OECD, n.d.).

Scenarios have to start from the here and now, no matter how much they take account of the past. This also applies to the post-Covid future, linked to a rapidly evolving and hard to grasp present, and it is important to detect, understand and highlight its latent trends. At the time of writing consensus on the 'is-state' includes the possibility of Covid-19 to persist for a long time in its current or mutated form which means that lifestyles need to adjust to this 'new normal'. This includes long term policies of prevention and preparation for future pandemics beyond the scope of this paper. Another latent trend is that governments worldwide aim to realise economic recovery and to resolve practical issues emerging from over a year of cohabitation with Covid-19 accordingly. Technological innovations such as artificial intelligence and robotics will essentially influence businesses and economic institutions rather than social responsibility, while national interests as well as ideological standpoints will continue to motivate the political apparatus.

7.2 UN scenarios for post-Covid cities

In "Cities and Pandemics: Towards a More Just, Green and Healthy Future" (UN, 2021) the United Nations propose four issues for analysis and action: "rethink the form and function of the city"; "address systemic poverty and inequality in cities"; "rebuild a 'new normal' urban economy"; and "clarify urban legislation and governance arrangements".

According to the UN, different uses of buildings and outdoor spaces during the pandemic already point toward changes in urban morphologies, and provide an indication of how they could be made more resilient to recurrent pandemics. To this end, inclusive spatial planning should incorporate specific interventions designed to address inequalities in cities and mitigate their impact on poor and vulnerable groups. Most important for these changes is a more integrated and cooperative multi-level governance. With regard to the urban economy, tackling the crisis involves seeking innovative financing mechanisms for services and infrastructure while ensuring social protection programmes to encourage sustainable production and consumption patterns. It includes support for renewable energy transition, green building methods, land use regulation and investment in digital technologies to improve logistics and supply chains, as well as support for smaller enterprises, informal workers and risky sectors.

Such measures, together with inclusive local development would also contribute to enhancing social relationships, combating poverty and inequality in cities and improving living conditions for all. At a broader and necessarily longer term scale mismatch between populations, inequalities in the built fabric and occupancy rates which accelerated virus transmission would need to lead to restructuring city forms and functions. In conjunction it postulates nimble and flexible urban governance, as well as leadership acting transparently, building trust and fostering community engagement at all levels to obtain public support in crisis situations, get short term measures accepted and produce sustainable long term solutions.

7.3 Scenarios for a new understanding of sustainable cities

The scenarios presented here are visualised in terms of their overarching goals: ‘business as usual, ‘genuinely-sustainable’, ‘build-back-better’, ‘pragmatic-realistic’. They rest on the dialectic between people’s right to the city and the tasks of political-administrative governance to balance economic, environmental and social development equitably. However, any post-Covid future remains constrained by the staying power of both human behaviour and political interests. This pragmatic selection of four scenarios is based on people’s preoccupations about their future during the pandemic on the one hand and the political roadmaps on the other hand, both set against an ideal-state akin to that depicted by the UN.

Nevertheless, the scenarios focus on a ‘new normal’ framed by past habits, responses provoked by Covid-19 disruptions, political interventions at all levels, together with events outside anyone’s control. Combined with creative initiatives in everyday life all these aspects are contributing to shaping the changes towards a post-Covid reality. After initial optimism and activism, the mood has been hardening with Covid fatigue and the ‘new normal’ could well be less palatable than the old one, expressed in the ‘business as usual’ scenario. Although a return to the ‘old normal’ is not considered desirable it is acknowledged as a very realistic option and therefore the “materialistic scenario” follows current trends and projects them into the short and medium term.

Conversely, the other scenarios are imagining a range of possible sustainable futures based on promising changes which took place during the pandemic and starting points detected for local action and related governance reform and they also propose examples of practical planning and urban design solutions. The sustainable scenario projects the desired future for a better world; the optimistic scenario proposes the lines to follow under new rules of the game; and the expert foresight proposes feasible proposals.

7.4 Back to the pre-Covid scenario: a return to the ‘normal’ past?

This urban scenario overcomes the limitations of the "new normal" and returns to the "normal" trends of the previous context. Even if it adopts certain changes in economic, social and environmental attitudes, its effects will remain limited as long as the deep structures of society remain intact. Despite serious warnings about climate change, systematic destruction of the environment, increasing social polarisation and political imbalances, there will be no substantial changes that will help the model to adapt and develop.

Its economic context is a very flexible capitalist system which will recover rapidly, organising new models of production, especially those related to the collection, management and commercialisation of data (surveillance capitalism). Global corporations, the concentration of power and decision-making and the accumulation of large fortunes will become more widespread. Even if companies are adopting criteria of social responsibility and respect for the environment ("green capitalism", "green and digital transformation"), the economy would take time to decarbonise, create jobs and reduce poverty. Demand for goods and services and for energy and materials will continue to rise. The loss of trade union power, the disappearance of regulatory agencies and the removal of control over international movements of capital, fuelled by digital technology, will increase the polarisation between rich and poor and deepen inequality, precariousness, unemployment and urban poverty.

In urban societies people's daily behaviour will return to previous lifestyles, albeit embracing the changes brought about by digitisation during the pandemic of work, shopping, education and leisure. Teleworking will lead to sedentary lifestyles and isolation, with physical and mental consequences for some segments of

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

the population, accentuating the symptom of burnout generated by the freely assumed obligation to maximise personal productivity. Collective awareness will disappear in favour of "Covid-NIMBYism": let others take precautions. The economic downturn will impose harsh conditions: precariousness of employment, increase in temporary work (the gig economy), need to adapt to professional transitions and polarisation of income related to types of activities.

Regarding city form and function the rise of telework, tele-education, tele-health and techno-finance are likely to stimulate migration from metropolitan regions to medium-sized cities, towns and suburbs which could increase their economy, cultural life and diversity if people take root. The search for safe urban spaces will promote segregation between traditional neighbourhoods and self-sufficient neighbourhoods with locally generated energy and self-sustaining agriculture, small-scale industries, proximity care services, coworking spaces and telework-friendly housing. Housing will become an even more essential commodity, increasing its value in the housing market. The lack of social housing in favour of public rental policies will deepen social inequality.

In terms of governance the role of the political-administrative apparatus will have to focus on balancing emerging social, economic and environmental tensions. The positioning of the sectoral groups affected and the entrenchment of the prevailing ideological parameters on the political left and right will generate circumstances that are difficult to control: loss of confidence in governments and political parties, deterioration of democracies, strengthening of extremist movements, consolidation of populism and independence movements and the reduction of the welfare state will generate massive protests.

7.5 Genuinely Sustainable Scenario: a universal paradigm?

Such an ‘ideal-state’ future is improbable but could be an inspiration for a desirable and possibly necessary future. It combines the three e’s of sustainability: economy, environment and equity, together with taming and preventing pandemics. It aims at universal human material wellbeing, ecological survival of the planet and inclusive social-spatial justice. What underpins this blue-sky-thinking is that these dimensions are totally interdependent for a sustainable future. Efforts to reduce green-house-gas emissions had been displaced by fighting Covid-19 but climate change urgency remained in the forefront of collective consciousness, especially of younger generations. Conversely, the pandemic has exacerbated social divides and spatial segregation, most of all in deprived areas, often with disadvantaged populations and ethnic minorities, in greatest need of redressing. It means that economic recovery has to be accompanied by more integrated and cooperative governance, redistribution of resources, access to services for all and empowered citizenry. This applies to all levels from neighbourhoods to the global sphere, thus requires action and consensus among political opponents and across continents.

Unfortunately, even at the EU level on which this paper is focusing, agreement on how to operationalise the New Green Deal remains under debate, although there seems to be convergence on the climate change targets. However that leaves divergent views on economic recovery, with those opting for austerity and self-reliance, while others are seeking more inclusive solutions with fairer tax burden sharing and solidarity across generations and territories regarding employment and welfare support. Only thus can social and spatial polarisation be redressed comprehensively, based on regenerative economy and a sustainable ecological footprint: in this scenario the foundation of ‘build back better’.

Such an "ideal" future also promoted by the Leipzig Charter is improbable but inspiring as it proposes to coordinate interdependent responses that are difficult to connect: sustainable economic recovery; redressing of growing social and spatial polarisation, including the digital divide; action on the environment, especially climate change; and anticipation and prevention of pandemics and other catastrophic events. Nevertheless, over the last three decades many initiatives have been taken at city level to achieve a greener economy and a more equitable future achieved by more integrated and cooperative urban governance. Under the constraints of the pandemic, designers focused on compact, mixed-use neighbourhoods which make it possible to satisfy basic needs within walking distance, with a road network that supports active mobility and more accessible and equitable green spaces as a move towards the morphologically sustainable city. The pandemic led to more neighbourhood living and non-motorised travel, although reduced use of public transport remains unrealistic for cities dependent on mass transit. In some cities participatory platforms for decision-making based on the views of residents, entrepreneurs and community organisations were promoted and were effective in meeting the needs of residents during mandatory lockdowns.

To what extent political decision makers will seek post pandemic synergy between alleviating and/or preventing future pandemics, coping with climate change urgency, redressing the growing social and spatial inequalities in cities and dealing with the need for governance reform remains unknown, although such an integrated approach may be the only viable strategy for the long term survival of the planet and humankind.

7.6 "Build-Back-Better" Scenario: towards a new social contract?

Aiming at a return to the 'old normal' seems unrealistic and undesirable. However, a 'new normal' - a post-Covid or with-Covid future may either be better, albeit most likely only in parts, or worse, with increasing polarisation within and between cities and countries as well as globally; only paying lip service to targets for climate change with little or no action, everyone waiting for others to take the lead in accepting environmental constraints and reducing consumption; and leading to a neo-liberal economy with even fewer regulations and welfare provision.

Politically "Build-back-better" is understood as a 'new normal' after the pandemic whose economic recovery has to include a plan to repay unprecedented national debts, reinstate jobs and restore economic sectors particularly damaged by past lockdowns. So far, there is little sign of fresh, let alone structural or innovative government rethinking towards a more equitable future. Speed of economic recovery considered essential for a better livelihood is of the essence, to which all other needs - better lives, health and social care are subordinated. During Covid, spontaneous, shared and sometimes altruistic initiatives have given way to sectarian claims competing for dwindling public resources and financial support, thus short-termism towards "build-back-better" may lead to harsher, skewed hardship and conflicts. In some countries, government emergency laws claiming to pursue unity gave rise to exceptional powers and centralisation which, if not reversed, may well provoke claims for more devolution of decision-making and resources, and thus to fragmented and uneven economic and social recovery.

The pandemic has highlighted the mismatch between population size, high densities, overcrowding, virus transmission and mortality rates globally, although cities are better equipped to absorb the effects of calamities. Spatial inequalities manifest themselves in physical segregation as well as uneven distribution and access to basic services and infrastructure, affecting deprived urban areas most, but also low density remote suburbs. Change of use of spaces in cities due to the pandemic and lockdowns is pointing towards more permanent urban transformations. For example, the design of urban spaces will be relevant in accommodating more and safe outdoor activities, improving hygiene measures, converting buildings to absorb home-working and designing buildings for more flexible use. It will be necessary to rethink planning regulations and building codes to manage safe, affordable, reliable and efficient public services, including reducing the digital divide in disadvantaged communities. It will require neighbourhood improvement strategies and the promotion of new lifestyles, new treatments of public space and the incorporation of mixed uses with co-working spaces to energise neighbourhoods. Quality of recovery should be led by pro-active local governments with public participation in inclusive planning and decision-making about the transformation of people's neighbourhoods into viable local economies satisfying both residents and businesses and a green and healthy environment. Transparency and trust building will be of the essence to obtain public support and facilitate compliance. Overall, as a desirable future "build back better" needs to redress spatial-social segregation and re-direct neo-liberal economics to ensure greater welfare.

7.7 Pragmatic-Realistic Scenario, towards a post-Covid form of capitalism?

For this scenario it is particularly important to have a clear understanding of the "is-state". The main transformations emerging from over a year under the influence of Covid-19 appear in change of working habits, shopping, education and mobility. Already homes and offices are being restructured to accommodate pandemic conditions. More homeworking is already leading to more diversified office activities and affecting mobility with lower use of public transport, more active movement, fewer trips made overall replaced by digital communication, as well as less travel and especially long distance journeys for leisure, business, and even possibly tourism. Clearly public transport is indispensable for the functioning of cities, and while cycling, walking and other personalised small scale mobilities like scooters and curbing especially single occupancy car journeys are positive contributions to curbing GHG emissions, the whole road network will have to be reimagined for a more sustainable modal balance which may also be affected by longer term need for social distancing. The issue of density of use as well as of buildings will need revisiting and allowances made for more open and green spaces, public and private in cities, including spaces for growing food and local recreation. The accelerated shift to online shopping is affecting retail premises. All these changes are having adverse impacts on hospitality, culture and leisure, most acutely in centres of large cities which usually concentrate a broad range of urban functions. The current empty premises due to fewer commuters and tourists, at least in the short term, have left behind blind ground floors and less footfall and require innovative solutions for the recovery of city centres.

These and many other urban design considerations are serious challenges for planners, designers and the property industry, but they present opportunities for creative newcomers with creative ideas about post-Covid urban life. Small scale, alternative, experimental, doable and already realised regeneration projects, recycling and in-fill buildings can add up and make a valuable contribution to urban sustainability. However, they are neither comprehensive nor 'universal' and cannot replace the current strategic political objectives of the current neo-liberal economic capitalistic system.

The 'pragmatic-realistic' scenario which is geared towards cities concentrates on initiatives likely to become the focus of post-pandemic reality.

8 CONCLUSION

This paper imagines four scenarios for cities in the near future based on the social, economic, environmental and political processes generated during the pandemic. The content of these scenarios rests on a two-prong basis: proposals for actions at European (Leipzig Charter) and international (UN New Urban Agenda) levels providing the methodological framework; and the urban situation facing the health crisis, revealing the lack of resilience of cities to cope with unexpected calamities.

The paper outlines four different visions of the path that cities could take in the near future:

- one that continues past trends
- one that projects a desired future for a better world
- one that proposes to change the rules of the game
- one that seeks feasible proposals within the current state of affairs.

It is recognised that the results of all four paths will always be partial. They may not even be encouraging, considering the weight of the legacy of existing cities and, in particular, their material constraints and political-administrative structures. As the pandemic left the basic material structure of cities intact there is no urgency of reconstruction, except for social coexistence.

The future will also be shaped by ongoing social, economic and environmental processes taking place in cities. In part they depend on a network of global relations framed by international treaties like the UN sustainability goals and the Leipzig Charter objectives aimed to steer their implementation, albeit with uneven and unpredictable results in practice. Conversely, Covid-19 has also unleashed fragmentation of the globalising world and retrenchment on local concerns which may make cities looking more inward. Added to these contradictory trends is uncertainty of both collective and individual human behaviour and how they will influence the realisation of change.

Nevertheless, several issues have been emerging during the pandemic which are likely to persist or be desirable to retain after recovery:

- value of science in its mission to save humanity
- increase in the symptom of burnout, driven by the need to increase performance by a model of exploitation without legitimacy
- need to change lifestyles which proved their limitations during confinement.

Covid-19 is not the first and will not be the last pandemic, but it is hoped that its consequences will serve as a lever for change to improve living conditions in cities.

1 ABSTRACT

Due to the corona crisis and its consequences for the target group 65+, the term autonomy and self-determination in old age was assigned a further great meaning and is becoming extremely important. 43 percent of corona deaths in Austria are residents of retirement and nursing homes.[1]Mental illnesses as a result, caused by isolation, such as restrictions on going out and visiting by others and the fear of dying alone. All of these are factors that drastically reduce the demand for the traditional nursing home as a residence for the 65+ target group. And still, we are right in the middle of the age shift due to demographic change, which increase the need for adaptation of the living environment. The over 65-year-old population in Europe is forecast to increase by an average of up to 55% by 2050.[2]

Housing in connection with the urban environment is an essential factor to remain autonomous.Housing must not be considered in isolation, but in context. Here, not only one's own home plays an important role, but also public space and open space. This paper will use the research survey of 307 people of the 65+ target group living in Graz to investigate what conditions need to be met in order to create an age-friendly district where people 65+ can live autonomously. Questions were asked in the areas of digitalisation, social life, infrastructure and mobility, in relation to habit and relevance. 86% would not think of changing their residence, the idea of leaving one's own home to become dependent is not widely accepted. Here, the public space in the immediate vicinity of the housing situation is a decisive factor because it is a place of social interaction. A place where collective life is created. Loneliness in old age is often accompanied by the lack of accessibility to public spaces. How should public space be designed for the daily walk? What distances are manageable for daily errands? Living in connection with the external context, such as a barrier-free accessible green space, is important for over 95 percent of the target group. The daily route must be barrier-free and easily manageable. Infrastructure, mobility and public space play a major role here. Homes and their associated open spaces must have alternative concepts to strengthen connections and promote community. Using the survey results as a foundation for a senior-friendly city, this paper looks at factors for a better quality of life. In view of demographic change, urban development must go hand in hand with the requirements of public space. Based on the survey a principle recommendation for the transformation of public space are suggested. It means high-quality designed public spaces in combination with easily accessible, barrier-free mobility and infrastructure.

Keywords: urban living environment, public space, age-friendly, mobility, autonomy

2 DEMOGRAPHIC CHANGE

Demographic change describes the adjustment of the age structure in relation to the changed living conditions of a population. It is a result of social upheavals caused by a change in the composition of the age structure in society.[3] In our affluent society, people not only live longer, but also age more slowly. This higher life expectancy is the result of growing prosperity, hygiene and health care, advances in medicine and accident prevention.[4]According to the study "Europas demografische Zukunft", prepared by the Berlin Institute for Population and Development in 2017, European demographic trends are projected to increase the number of people over 65 in Europe by an average of 55% in 2050.[5]Not only a change in the age structure of society, but for example the composition of the population structure in a spatial context is referred to as demographic change. Demographic change also brings with it an increasing number of people in need of care, among other things due to a high number of single households. In Austria, the number of household members per household fell on average from 3.11 persons to 2.22 persons between 1951 and 2018.This reduction in household sizes brought with it an increase in one-person households. According to

Statistics Austria, the share of single households was already 37.2% of the total number of private households in Austria in 2018.[6] Thus, the number of people living in cities will also increase. Demographic change is accompanied by an increase in the ageing population and thus attributes great importance to the housing situation and the associated local area in terms of independence in old age in the form of age-appropriate cities and neighbourhoods.[7]

3 INTEGRAL LIVING

Housing in conjunction with the urban environment is an essential factor in being able to live independently in old age. It must not be considered in isolation, but in context. Not only one's own home plays an important role, but also public space and open space. The socio-spatial context can act as a barrier or as a conducive support and compensate for possible missing competences as well as health restrictions.[8] A good example is the consideration of a "mini master plan" for each building, each flat, where housing is considered as a building block in the context of the city. In Brussels, this approach is already used as an operational tool to support the construction of social housing, in order to think about the necessary infrastructure with surroundings in the planning.[9]The flat must remain interesting as a living space even in old age, be it through the exciting view offered in combination with the visual relationships, the public space, meeting zones or community facilities. Fields of action for independent living in old age can be divided into three spatial scale levels: *Dwelling - centre of daily life *Open space - meeting place *Social infrastructure - support in the neighbourhood.

In the form of the onion model, where different layers of private to public space are formed around one's own dwelling, the urban connection between one's own dwelling and the context can be illustrated. As the radius of action of older people decreases more and more, the layers that can be experienced towards the public space become smaller and smaller.[10]The path from the door of the flat to the public space is a place for spontaneous encounters. The entrance as a meeting space has a special quality of place and is of great importance especially for people with limited mobility.Intermediate spaces as semi-private spaces with a high frequency of encounters are transitions, such as threshold areas, ground floor zones, arcades and staircases.Public space as an extension of living space and as a recreational and communication space is becoming increasingly important.[11]An interconnected, small-scale development network serves as a foundation for short distances in the local area and the neighbourhood and forms the basis for encounters in public space. It is about connecting with the surroundings in order to pursue integrative, cross-district planning approaches to support in the ageing process.[12]

4 HOUSING AND AUTONOMY

Due to the Coronaviruscrisis and its consequences for the 65+ target group, the concept of autonomy and self-determination in old age has taken on even greater significance. One's own home as a person's private living space is associated with personal memories. The older a person is, the more time he or she spends on average in his or her own home, which therefore stands for safety, self-determination and security.[13] If independence in everyday life is no longer possible, this is often accompanied by a loss of self-determination to act in accordance with one's own wishes and interests.[14] Dependence, but also loss of independence and adaptation are negative associations that are associated with nursing homes.[15] The wish to spend the last phase of life at home, in familiar surroundings, rather than in a nursing home, was furtherstrengthened by the developments of the pandemic.Since the beginning of the coronavirus pandemic until 18.01.2021, 43 percent (2.855 people) of all COVID-19 deaths in Austria (6.568 people) have been residents of nursing homes.[16] Here, mobility is also seen as a prerequisite for quality of life and an important factor for a self-determined

5 DYNAMIC PLANNING

Dynamic development for dynamic family growth.What is needed are individual flats that can be combined and connected to grow, and be connected with other residents. Multiple use thus ensures a diverse, lively mix, for flats that have become too large, vacancies or even communal areas. A small flat that can grow into a family flat and then shrink again when there is less demand because the costs are high or loneliness threatens are in demand.[18]Dynamic planning also means planning for accessibility. Accessibility is essential for 10% and important for 30%, but it is an advantage for every user.[19] Dynamic planning can also have a supporting and helping effect for the ageing population through the dynamic use and occupation of the areas in the neighbourhood. Thus, various additional services such as delivery services, common rooms, household support services,caretaker and shopping services as well as senior citizens' offices can be available.

6 LIVING IN OLD AGE

If the retirement from working life is taken as the entry into the old age phase, as well as the increased life expectancy and biological age, the result is the old age phase with a period of up to more than 30 years. If the varying circumstances and lifestyles are added to this, it becomes apparent that old age is made up of the most diverse processes with great variety and the differences are clear.[20] In old age, everyday life largely means everyday living in one's own home and local area. A survey in Zurich even showed that the target group65+ had been living in the same home for an average of 30 years at the time of the survey. Of the participants surveyed, 68% stated a very high degree of attachment to their own home. However, if a change of flat was imminent, 77% of the respondents would prefer a flat in the same neighbourhood.[21] Due to an increasing "singularisation" of the older population and the loneliness associated with it, there is additional interest in alternative forms of living, such as the concept of "living for help", where living space is shared between students and people who need help in the house. Other alternative forms of housing would be assisted living, living in a multi-generational house or an assisted living group, and co-housing. Recognisable motives are the avoidance of loneliness and the possibility of mutual support.[22]

7 TARGET GROUP SURVEY 65+

The survey of 307 people of the target group 65+ living in Graz was conducted over a period of four months, from August to November 2020, and shows which conditions must be fulfilled in order to create an age-friendly district in which people 65+ can live self-determined lives. Questions were asked in the areas of digitalisation, social life, infrastructure and mobility, in terms of habit and relevance. A total of 62% were women and 38% men. 25.7% were between 65 - 69 years old, 18.2% between 70 - 74 years old. 26.4% of the respondents were 75 - 79 years old, 16% between 80 - 84 years old. 8.8% were in the 85 - 89 age group. 4.6% were in the 90 - 94 age group and 0.3% were over 95 years old at the time of the survey. The evaluations showed that 95% were satisfied to very satisfied with their form of housing. For 46% of the respondents, the living situation is not accessible, but almost 86% are not willing to change their living situation. This shows great potential for urban development.

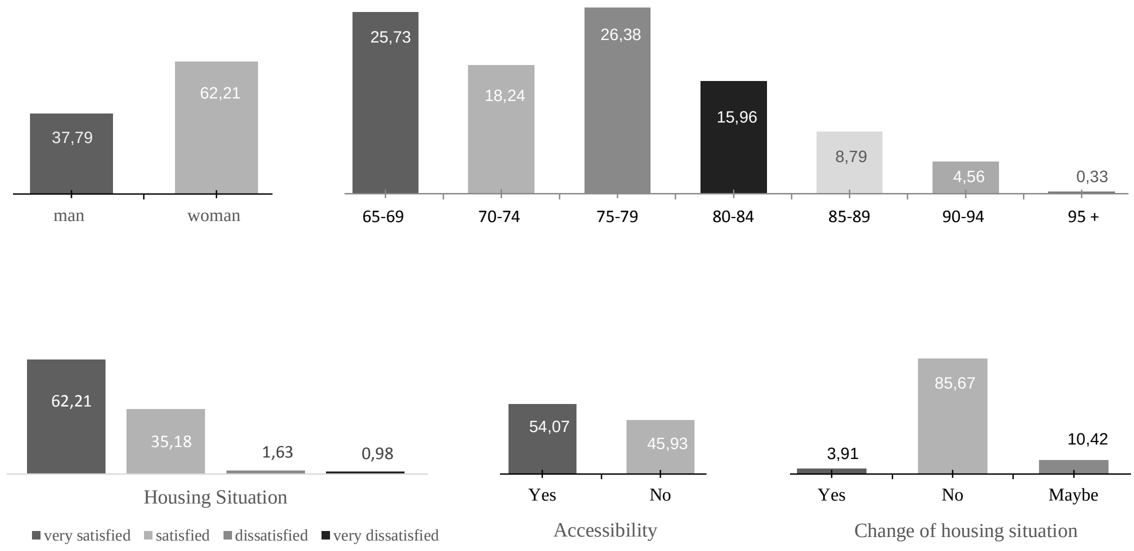

Fig. 2 Core data of the respondents

8 LIVING IN THE DISTRICT

Being able to lead a self-determined life even in old age is one of the essential attributes of successful preventive health care for older people. According to the survey of the 65+ target group in Graz, the ageing population also wants to be able to stay at home as long as possible. What is important here is the supply structure in combination with the concerns of the ageing population. Urban planning can help here. With declining mobility and health, the radius of action is concentrated on the local area and the district as a level of action.[23] What does the city need as a living space? The public space in the immediate vicinity of the living situation is a decisive factor, because it is a place of social interaction. A place where collective life is created. Loneliness in old age is often supported by the lack of accessibility to public space. Accessibility is considered an important factor, as 87% find accessibility to public space important. Open space plays a central role in the design of age-friendly and liveable urban districts and serves as a place for movement and encounters as well as a connection between different places. Accessibility, well-connected open spaces are especially important for older people due to their ever decreasing radius of action.[24]Short distances are essential, the survey makes this clear. A districts is defined as an individually considered area that can be reached on foot in everyday life. In the survey, a distance of 1500m was considered a realistic walking distance by only 40%. However, a distance of 500m is manageable on foot for 84% of the respondents. This results in a clear recommendation for a 500m radius in the neighbourhood. The routes for daily needs should therefore be designed with a maximum distance of 500 metres, as thisdistance can be reached in up to 15 minutes, even at a walking speed of 0.7 m/s.[25] Short distances to medical care, short distances to shopping and short distances to green spaces are very important to important for 94%.The daily commute must be accessibleand easy to manage. Infrastructure, mobility and public space play a major role here.

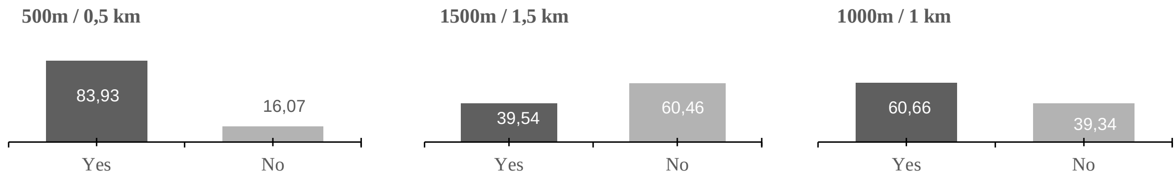

Fig. 3: manageable walk distance of the respondents

[24]Kreuzer/Reicher/Scholz 2008, 124.
[25]Kreuzer/Scholz 2011, 36.

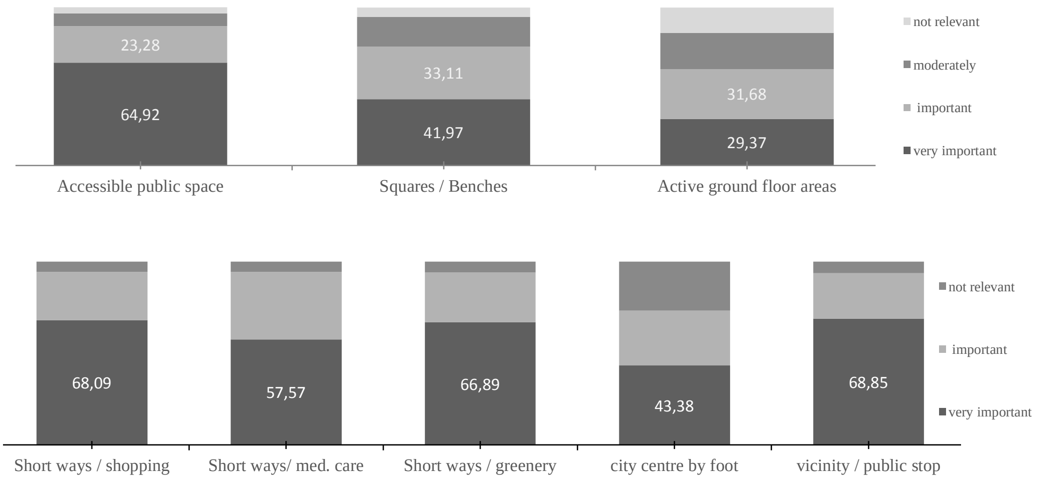

Fig. 4: distance preferences of the respondents

The survey also revealed wishes in the area of public space and mobility. Wishes in the area of pavements (9%) concern a sufficiently wide pavement separated from bicycle traffic and a barrier-free design, as well as sufficient lighting. Pedestrian crossings (16%) was also reported as a stressful situation because the green phase does not last long enough. There is also a desire for sufficient seating in public spaces (13%), as well as accessible waste collection points and letterboxes.In the area of public transport (48%), accessibleaccess to bus stops, avoidance of jerky braking behaviour, lower travel speeds, assistance with ticket purchase, as well as longer waiting times when getting on and off the bus were noted. The wish was also expressed for a separate bus for senior citizens, which would explicitly take into account the needs of the older population.

Pedestrian crossings 16%
more time to cross
Public transport 48 %
Improve public transport / shorter intervals
Less jerky braking and driving away too quickly
Illuminate bus stops
accessible stops/bus stations
secure seating for senior citizens
more time to get in and out

public space 13,04%
more public green spaces
More benches
Accessible waste collection points
More post boxes and public toilets
Pavement 9 %
Accessible pavements
Separate cycle paths and pavements
No additional boards on the pavement

Table 1: wishes regarding urban development

9 COMMUNITY

In the future, greater importance will be attributed to personal non-family associations such as neighbourhoods. The survey showed that 46% are very satisfied and 26% are satisfied with their neighbourhood relations. More networking would be desired by 44% of the respondents.

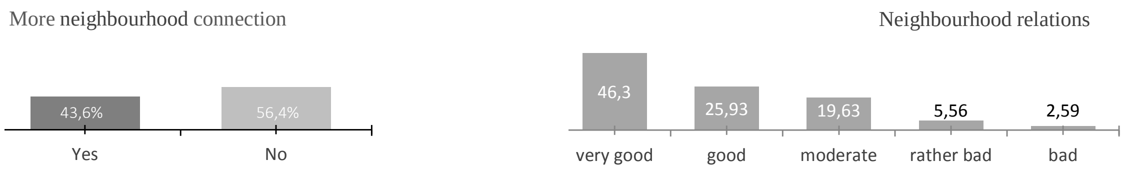

Fig. 5: Neighbourhood

Assistance and mutual support as well as the desire for community are wishes of the 65+ target group that can be supported by the choice of housing form and the resulting social network, because assistance and participation in the community has a great impact on a self-determined life in old age and already begins with minimal everyday help or manual work. Interpersonal contacts and conversations as well as emotional

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

support of social networks make an important contribution to the subjective quality of life.[26] A better cohesion is also created through joint activities such as cooking together or working in the community garden. Good togetherness requires a harmonious coexistence, not only a taking but also a giving. Reciprocal relationships and interactions, such as sharing, which takes on new relevance, are seen as an important element of house communities. Networking, swapping and sharing knowledge, food, services and everyday objects can also save costs in daily life. Neighbourhood help is seen as an essential element for independent living in old age.[27]

10 PRODUCTIVITY AS A BOND BETWEEN LIVING SPACE AND ENVIRONMENT

It is not only about living, but about fulfilling a task. In this sense, the idea of extended family in the form of neighbourhood help and personal productivity is also important.Studies show that voluntary engagement in old age is associated with higher life satisfaction and mental and physical health. This positive effect of activity on one's own well-being is explained with the help of activity theory. This states that the satisfaction of older people is significantly promoted by active participation in life and the maintenance of their social network. More community can also mean more infrastructure. In addition to the possibility of spatially undefined voluntary activities, active neighbourhood assistance also offers the possibility of exercising these activities in the spatial context of one's own environment. Neighbourhoodhelpincludes: minor assistance, personal conversations, looking after the flat and house,social get-togethers and childcare.In social associations, however, the older population does not only act as recipients of help, but also makes valuable contributions themselves. For example, cooking or childcare can be taken over by the older population, while the younger generation pursues their working lives. Almost 40% of the respondents look after children from time to time and attend anassociation meeting at least once a week. The 65+ target group is involved in voluntary work in various areas. This involvement increases with retirement and decreases again with advancing age.[28]The older population wants to be needed. For example, at the Viennese "Café Vollpension", seniors can supplement their income by baking cakes. This offer is so well received that there are not enough places for all applicants. Participation, even in old age, is important. The participation rate of respondents in Graz in association life is 49% and there is also a high level of professional and voluntary activity in retirement at 30%. Around 30% of the respondents attend courses on average every month. Community and public spaces are also perceived as very positive. In the evaluation of the personal favourite place, one's own home gained the highest value with 37.4%. Social areas such as common rooms with 4.8% and family and friends with 3.4% also make up a significant part of the personal favourite place.

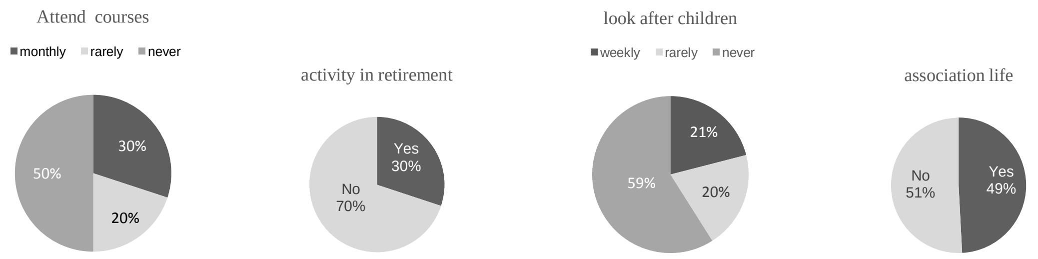

Fig.6 Activity of the respondents

personal favourite place	%
at home/ in the flat	37,43
garden / inner courtyard	15,92
Balcony & Terrace	13,41
nature / park	13,13
with family or friends	3,35
activity room / common room	4,75

Most mentioned activities in retirement	%
association life / social activity	19,00
Self-employment	16,53
Consulting and Coaching	12,40
construction site work	9,92
office work	9,09
organisation	8,26

11 CONCLUSION

The municipality plays a central role in the integrative planning process of an age-friendly city and cannot be considered separately. Social infrastructure in the neighbourhood is important, because networking in the community has a significant influence on housing satisfaction and is an important quality feature. Community spaces are important, because housing cannot be considered autonomously. In the future, the social aspect should be considered even more strongly in the planning and design of neighbourhoods. Housing must be thought of in the context of social and community services to promote quality of life, satisfaction and independence of older people.Demographic change will anchor the promotion of productivity and the associated participation in social life of older people as an essential task in our society.[29]In this way, living as independently as possible in old age is to be promoted and made possible by a lively neighbourhood in the trusted residential environment through mutual support.

1 ABSTRACT

Online commerce is an expanding and therefore challenging market. Due to its complexity, innovative solutions are required to guarantee a resource-saving supply quality with flexible goods and services in urban and rural areas. The challenges lie in developing an economically, ecologically and socially sustainable receiving and shipping system that offers the possibility of directly involving the local economy and strengthening locations overall. In particular, overcoming the last-mile in parcel delivery by courier express parcel services (CEP services) is associated with numerous problems.

Based on these logistical-organisational problems and challenges, vendor-independent ("white-label") parcel lockers were developed within the alBOX research project framework. Therefore, a pilot operation of white-label parcel systems in two target areas with different settlement structures (rural community of Kaumberg in Lower Austria and Vienna's 5th district Margareten) was implemented for twelve months. The implementation of the white-label parcel lockers system was accompanied by conducting a mixed methods research which uses quantitative data (e.g. average package sizes, frequency of orders, usage times etc.) as well as qualitative data (e.g. user experience, operability etc.) to test, analyse and evaluate this innovative service.

In this paper, the project's results are linked to delivery and distribution logistics' challenges to explain white-label parcel lockers' contribution to ensure a nationwide, innovative and demand-oriented (local) supply structure for spatially scalable and flexible flows of goods, information and services. For this purpose, supply-related, social, economic, and ecologically and environmentally relevant objectives were considered. The focus is on the results that describe the delivery situation from the recipients' perspective and their usage behaviour. It is discussed to what extent the parcel lockers as the first delivery address influence the delivery situation in the target areas of the pilot operation.

Keywords: white label, parcel lockers, last mile, CEP, distribution logistics

2 CURRENT SITUATION

Parcel lockers with permanent access are currently offered mostly by those CEP service providers with a corresponding market share in the respective segment. This development can lead to monopolies, especially in rural regions, with all the associated disadvantages. The parcel lockers of the two strongest providers, Post AG and Amazon, are managed exclusively as a closed system. So they are not accessible to other retailers and CEP delivery companies. In terms of cream-skimming, competition will primarily arise where there is particularly high demand. This will possibly (see LTE or 5G network) lead to spatial disparities. Local trade and the use of parcel lockers for municipal purposes (secure deposit of objects/documents between private individuals or public institutions) will be excluded from this service. It is comparatively more difficult to supply the local population with goods and services in rural and sparsely populated regions. The range of products in local stationary retail is mostly reduced to the essentials. Partly online retailing compensate for disparities in the supply quality of communities with retail and specialised shops between urban and rural areas (Gumz et al. 2020). Furthermore, an increase in online trade puts pressure on regional traders in peripheral areas. Platforms for the joint marketing of products or the bundled provision of products and services can sustainably strengthen retail and direct marketing in rural areas (Mensing 2016).

In order to capture the current developments in the delivery industry, especially concerning parcel lockers in Vienna and Lower Austria, a spatial analysis by Gregory Consultings (2019) and a survey by Logistic 2030 are combined in Figure 1. Thus, the development of the number of parcel locker locations per provider in Vienna and Lower Austria is summarised for the period March 2019 to October 2020. Furthermore, the figure shows the proportions of open and closed systems in the respective periods. From March to October 2019, the delivery service DHL closed all of its 28 parcel stations.

By October 2019, Variocube, a new provider, comes along. A1 triples, and Renz almost doubles its number of locations. In 2020, on the other hand, only Interspar will reduce its number of locations, while Myflexbox and Amazon will become new providers. Outstanding is that, despite the new start of Amazon, it takes immediate third place among the providers with the most locations in Vienna and Lower Austria. Renz, A1 and Variocube doubled their number of locations in this period. Post AG can also show an increase of 32%.

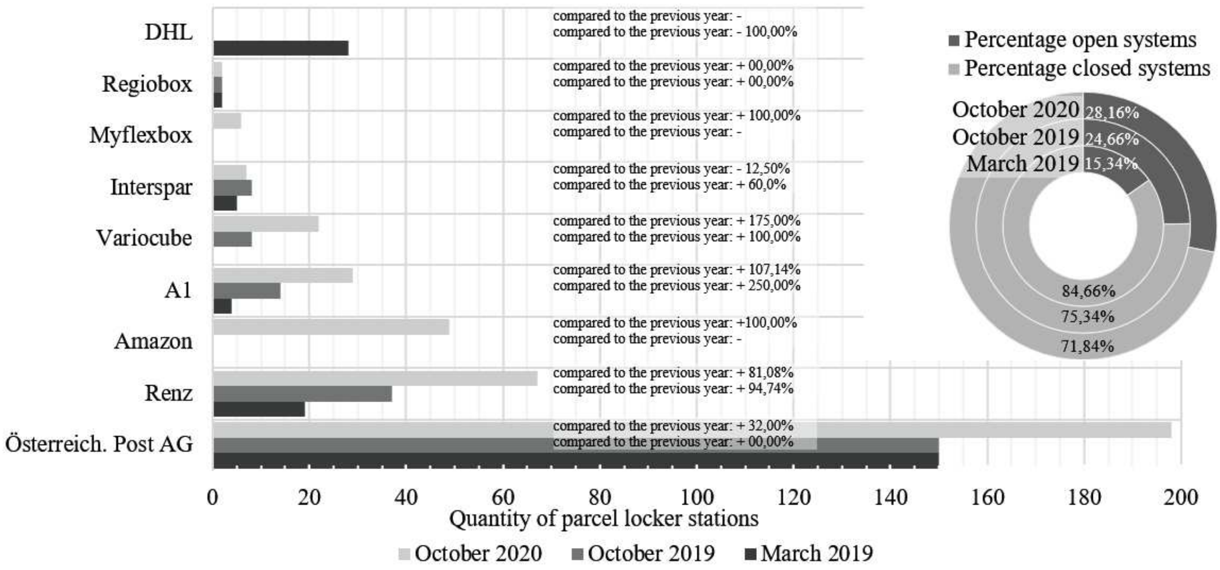

Fig. 1: Development of the number of parcel locker stations in Vienna and Lower Austria in the period of March 2019 until October 2020, Source: own calculation, Data: (Wirtschaftskammer Wien 2020 and Gregori Consulting 2019)

Overcoming the last mile in the delivery logistics of CEP companies is associated with numerous economic and ecological challenges. The traffic induced by parcel delivery increases, especially when the first delivery attempt at the recipients fails. If additional journeys have to be made by CEP providers and recipients to pick-up the parcel from a parcel shop in the vicinity, more time-, travel- and CO2-costs are generated.

To this end, Prandtstetter et al. (2021) calculate simulations using models conducted as part of the alBOX research project. Depending on the parameters "rate of successful first deliveries", "rate of recipients using parcel lockers", "rate of collecting parcels exclusively" and the selected region in combination with the corresponding modal split, distances travelled, and CO2 emissions of delivery traffic are determined for each scenario. A comparison of the results shows that parcel lockers can significantly help to reduce CO2 and achieve distance savings if their location can be easily integrated into the delivery process.

2.1 Comparison of existing forms of parcel lockers

Various systems exist for the delivery of parcels when recipients are absent. Those pick-up points for parcels are structurally bound to a location and have a particular spatial catchment area. They handle the delivery process of parcels without direct contact between the delivering company and the recipient. In a summary of national and international reception and dispatch systems, a distinction can be made between time-bound pick-up points and time-independent locker systems.

Time-bound pick-up points differentiate between directly at the residence or work located ones and those that are public and staffed. Pick-up points for parcels can be provided by partner shops of the CEP services or operated by the particular CEP services. The principle of the CEP partner shop is linked to existing infrastructures and is based on the time-efficient drop-off and pick-up of parcels. The integration of this process into the recipient's daily consumption routine is essential.

Building-integrated, time-independent parcel locker systems at the place of residence are a new dimension of shipment consolidation. The delivery of parcels is completely decoupled from the presence of the recipient and staff. Recipients and CEP services can access and process parcel shipments 24 hours a day. Public parcel locker systems can be provided by one CEP service or be operated by several CEP services.

2.2 Development of the mail order business in Austria

According to a European survey on ICT use, the proportion of people using online shopping increased enormously between 2003 and 2019 (Figure 2). Between 2003 and 2015, the target group of 25 to 34 year-olds made the most use of online shopping. However, from 2015 onwards, 16 to 24 year-olds are equally represented, as are people in the 35 to 44 age group. The year 2016 is remarkable because a decline in online shopping is noticeable in all age groups, except for the 25 to 34 year-olds and 65 to 74 year-olds (Statistik Austria 2019).

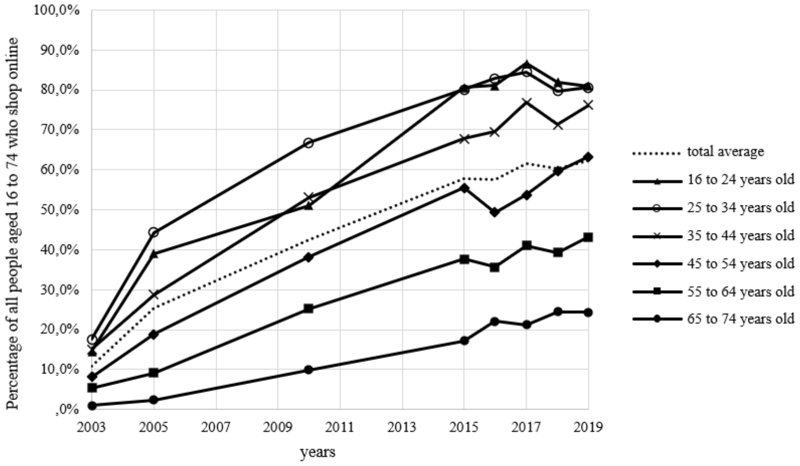

Fig. 2: Development of the proportion of people who shop online per age group; Data: (Statistik Austria 2019), own computation

The proportion of companies in Austria that are exclusively active in online retailing, and thus belong to the ÖNACE category Mail-order and Internet Retailing G4791, is continuously increasing. Figure 3 shows this increase and the percentage change in the number of companies compared to the previous year. After a substantial increase in companies in this sector of +36.33% between 2008 and 2009, the growth rates of percentage change per year are in the range of around 6-11% (Statistik Austria 2017).

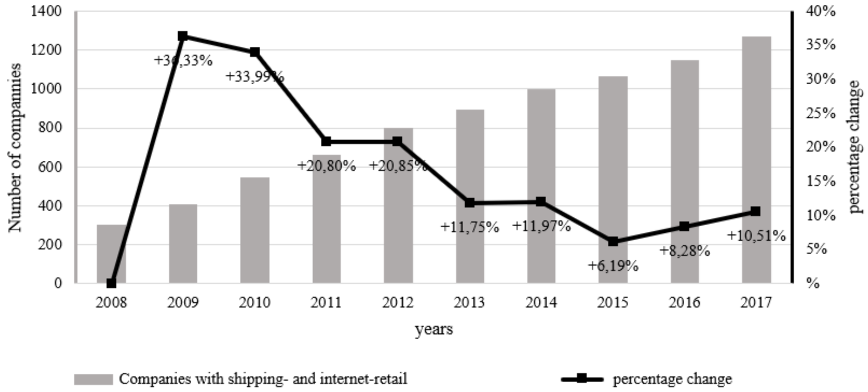

Fig. 3: Development of the number of companies belonging to the ÖNACE category G4791 - mail-order and internet retail trade; Data: (Statistik Austria 2017), own computation

3 WHITE-LABEL PARCEL LOCKERS

In the course of the alBOX research project, vendor-independent ("white-label") parcel lockers were developed as receiving and shipping systems for parcels and objects. Subsequently, the white-label parcel lockers were implemented as pilot operation in the two different target areas (rural community of Kaumberg in Lower Austria and Vienna's 5th district Margareten). In addition, the project investigates which further innovative services of white-label parcel lockers can lead to more overall municipal added values. In order

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

for different groups of stakeholders to use the white-label parcel lockers, the interests of the recipients, operators, companies, municipal decision-makers, and logistics service providers are taken into account during the whole development process. For example, companies in the catchment area can offer their products and services via the white-label parcel lockers outside of their business hours with the help of the deposit function. The high degree of flexibility and independence between shipper and recipient in a delivery procedure via the white-label parcel lockers enables more efficient route bundling. Moreover, the white-label parcel lockers counteract the disparities in the delivery speed and efficiency of goods that occur in rural areas compared to urban centres.

The white-label parcel lockers currently have dimensions between 460 x 130 x 650 cm and 460 x 730 x 650 cm. They are weatherproof and designed to be tamper-proof. In Kaumberg the white-label parcel lockers are located outdoors, whereas at the location in 5th district of Vienna they are installed in the stairwell of a residential building. Further, in contrast to Kaumberg, only a closed user group can use the white-label parcel lockers at the location in Vienna. The white-label parcel lockers run autonomously and can be operated by the recipients and CEP services themselves. So no additional staff is needed to handle the delivery process.

In the context of the pilot operation, only the identified core services are offered. That includes the vendor-independent receipt of parcels and the deposit of items between private individuals or companies. For this purpose, each customer receives a personal parcel locker number after registering online. In the course of an order process, the address of the parcel locker location and the personal parcel locker number is entered. After successful (parcel) delivery, customers receive a five-digit pick-up code per e-mail. This code is entered directly on the touchscreen monitor of the parcel locker installation to open the parcel locker. After the parcel has been removed, the compartment is closed again and is ready for the following delivery process. A transfer order is created via the customer's account on the provider's website to deposit items for other people. With this code, the compartment can be locked and opened again within a specific time.

3.1 Pilot operation rural community of Kaumberg, Lower Austria

Kaumberg, one of 12 municipalities located in the Triestingtal valley in Lower Austria, has a cadastral area of 4,303.7 ha, with a share of forest land of 63.52%. The municipality is served by the Hainfeld Road B 18, which runs from the Vienna Basin via Günselsdorf and Leobersdorf (connection to A2) to Traisen (Mostviertel) and connects the Triesting Valley with its municipalities Berndorf, Pottenstein, Weissenbach an der Triesting, Altenmarkt an der Triesting, Kaumberg, Hainfeld, Rohrbach an der Gölsen, Rainfeld and St. Veit an der Gölsen. By public transport, Kaumberg can be reached by train in combination with the Postbus or the taxi business Trixi. When looking at the population development, an increase of approx. 73% to 1,011 inhabitants in 2017 can be recorded since 1991. Of these, 623 inhabitants are in the 15-60 age group (Amt der NÖ Landesregierung 2019). The white-label parcel lockers are installed in the market square area at the address Markt 13, 2572 Kaumberg.

3.2 Pilot operation Vienna's 5th district Margareten

Margareten is the fifth district of Vienna and is located southwest within the Vienna Gürtel. It is densely built-up and very well connected to the high-level transport network by public transport, e.g. underground line 4. The district boundaries cover an area of 201.1 ha, of which 129.3 ha are subject to building land use. 8.8 ha are used as parklands, and 63 ha are used for transport. The population increased to 55,405 inhabitants between 2009 and 2019, which means an increase of 5.9% within the last ten years. Of these, approximately 27,000 residents of the municipality of Margareten have a migration background in 2019. The social infrastructure within the district is cosmopolitan and has a wide range of medical care as well as educational institutions (Stadt Wien 2020). The white-label parcel lockers were installed at the address Grohgasse 5-7, 1050 Wien Margareten. The location is about 350m walking distance from the underground station Pilgramgasse (U4).

4 METHODOLOGY

The objective is the comprehensive, integrative and experimental piloting of vendor-independent locker systems that can be sustainably integrated into the cityscape. For this purpose, various methods will be used to interview different stakeholders about the delivery situation on the last mile and the role of the white-label parcel lockers presented in the project. It will be determined how and which ecological, economic and social effects white-label parcel lockers can achieve on a long-term level. The observation period of the entire pilot operation is 12 months from 01.07.2019 to 30.06.2020.

4.1 Evaluation of the quantitative user data to detect the actual use of the white-label parcel lockers

For the examination of the actual usage, the main focus is on evaluating the quantitative usage data that is continuously collected by the software. Further, the customers provided personal data during registration for the creation of a customer account.

The datasheet was reviewed to identify outliers, test or spam accounts to exclude them from the evaluation. Data records were declared as outliers if parcels were deposited for less than ten minutes or longer than two weeks. The affected records are congruent with the expected assumptions and knowledge about periods in which testing was conducted, or system malfunctions occurred.

Overall, 31% of the registered clients used the white-label lockers in the catchment area of Vienna Margareten and 69% in the catchment area of Kaumberg Lower Austria. The persons participating in the pilot project were predominantly male with a share of 62% and part of the age groups covering the ranges 21 to 40 years. Of all registered clients from the catchment area of the white-label parcel lockers at the pilot location Kaumberg, 93% of the persons directly reside in the cadastral municipality of Kaumberg. In contrast, at the pilot location in Vienna Margareten, the parcel boxes are only accessible to delivery staff, residents of Grohgasse 5-7, 1050 Vienna, and to employees of the nearby Storebox Holding GmbH.

4.2 Qualitative survey of the usage behaviour and experiences of the participating users

Within the framework of the qualitative surveys, information on user experiences and user behaviour could be generated. For this purpose, a workshop was conducted among so-called heavy users (above-average number of parcel deliveries) on 29.10.2019 in Kaumberg. Only male users participated, who were between 26 and 40 years old. The majority stated that they have an irregular or flexible daily schedule. For this reason, the white-label parcel lockers are willingly accepted, as they are independent of the opening hours of the postal partners. However, during the workshop, experience reports were also shared that the service has already been tried out by older generations together with the workshop participants.

From May to June 2020, a six-week online survey was conducted among registered participants. A total of 34 people out of 65 contacted persons participated, resulting in a response rate of 52.3%. Of these, 2/3 stated that they use the white-label parcel lockers at the pilot location in Kaumberg Lower Austria, and 1/3 use the white-label parcel lockers in Vienna Margareten. A similar proportion is also found among the actual, registered users. In July 2020, 69% of the users resided in the catchment area of Kaumberg, and 31% of the users resided in the catchment area of Vienna Margareten. Of these, 50% were between 24 and 34 years old. The gender ratio among the participants is balanced at 50%. Furthermore, 90% of the participants are employed and just over half state that they have a regular daily routine on weekdays. The household size of the participating clients is predominantly composed of 2 people over the age of 18.

In the course of the implementation of the white-label parcel lockers, a service hotline was set up. The hotline can be called to communicate support messages, wishes and suggestions. After a large number of open questions had already been answered during the workshop, only a few messages were received via the alBOX service hotline.

4.3 Qualitative interviews with other stakeholder groups

To assess the relevance and potential of white-label parcel lockers, several interviews with other stakeholders were conducted. For example, experts from the fields of municipal development and logistics, e-commerce, entrepreneurs in the catchment areas of the white-label parcel lockers and drivers of the CEP providers who already used parcel lockers, administrative functionaries of Lower Austrian municipalities from different spatial typologies (Statistik Austria 2016) were interviewed. The interviews were executed by telephone and in person.

5 RESULTS

The implementation of the white-label parcel lockers is about testing a new technology, initially in the area of parcel delivery. The service was tested primarily by people in the age groups 24 to 44, of whom 62% of the registered participants are male. However, the gender ratio is balanced in the course of the survey of usability and user experiences. Even though only a small percentage of registered customers are over 64 years old, reports from the workshops show that people from the 64+ generation use the white-label parcel lockers. In the further development of the white-label parcel lockers and additional services, the idea of an inclusive service design should definitely be pushed in order to create added value for as many stakeholder groups as possible so that no social groups are excluded.

The workshop's results in Kaumberg in October 2019 differ slightly from the online survey in May/June 2020. However, it should be noted that the online survey surveyed a significantly larger group of people and not only heavy users from Kaumberg as in the workshop in October 2019. As a result, the trends in the data are comparable but significantly more differentiated. Furthermore, the workshop in October 2019 in Kaumberg did not record the detours or time spent collecting parcels from the WLP, in contrast to the much more comprehensive online survey from May/June 2020. With the possibility of receiving products via the white-label parcel lockers, customers' usage behaviour, time, and distance efforts changed.

5.1 General situation of distribution logistics in the target areas of the pilot operations

In October 2019, 75% of the surveyed heavy users stated that the parcels would be deposited in a parcel shop in the case of an unsuccessful delivery attempt. However, in the survey in May/June 2020, 29% of the participants from the catchment area of Kaumberg stated that this option is not desired or not satisfactory. In the workshop in October 2019 in Kaumberg, all participants said that without the option of having parcels delivered via the white-label parcel lockers, problems frequently arise on a scale of 1 to 4 (always - frequently - rarely - never) due to absence during delivery by the CEP service.

In the case of an unsuccessful first delivery attempt, various options for depositing parcels are possible. When asked about the frequency of delivery problems, only 3% of the survey participants stated that problems never occur. In contrast, 53% described regular delivery problems (6% almost always and 47% frequently) when the recipient is absent. In the case of an unsuccessful first delivery attempt, the parcel is usually collected in the immediate vicinity of the delivery address by about one-third of the participants, but 67% have to make a trip to a pick-up shop or a post office. In the online survey from May/June 2020, it was asked which locations are not desirable to deposit parcels from the recipients' point of view.

It should be noted that all respondents selected at least one inappropriate deposit location (Figure 4). In order to categorise the reasons why the stated deposit locations are undesirable, the qualitative statements were summarised in the course of a qualitative content analysis and thus divided into the respective superordinate categories (Mayring 2015). The superordinate categories are composed of the previously queried deposit locations and were then supplemented with subcategories, which were defined inductively based on the qualitative statements (Döring et al. 2016).

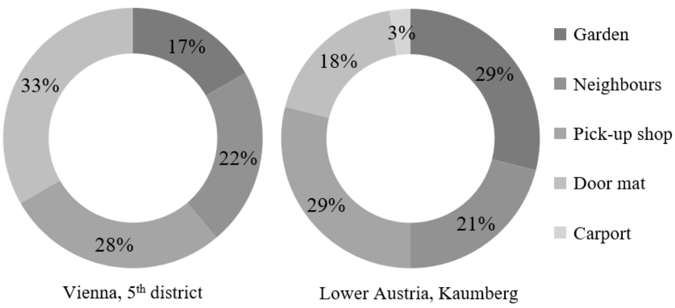

Fig. 4: Locations that are inappropriate for a parcel deposit from the participants' point of view (online survey May/June 2020)

Figure 5 should therefore be read so that the size of the rectangles in the graph represents the shares of the categories in the total number of justifications. It should be noted that each participant gave at least one reason. This shows which reasons occurred most frequently in relation to the others in connection with the superordinate category.

For example, a total of 33.3% of the statements referred to the fact that leaving the parcel in a parcel pick-up shop is undesirable. In this context, the necessary detours are a point of criticism for more than half of the participants, and for around 29% the limited opening hours are a reason why deliveries via a parcel pick-up shop are not desired. In the two categories "garden" and "door mat" the place of deposit was declared inappropriate in both cases due to the risk of theft. Furthermore, it was pointed out several times that dogs could carry away or destroy the parcels. Leaving parcels with the neighbours is inappropriate for the customers because they do not know them, or the possible pick-up time is very uncertain. Some described that the additional effort for the neighbours and for themselves is too great to accept the parcels.

Overall, the survey of the current distribution situation shows that it must be classified as problematic. The situation of the current range of options for depositing parcels is not satisfactory and can not be seen as a solution, but rather the lesser of two evils.

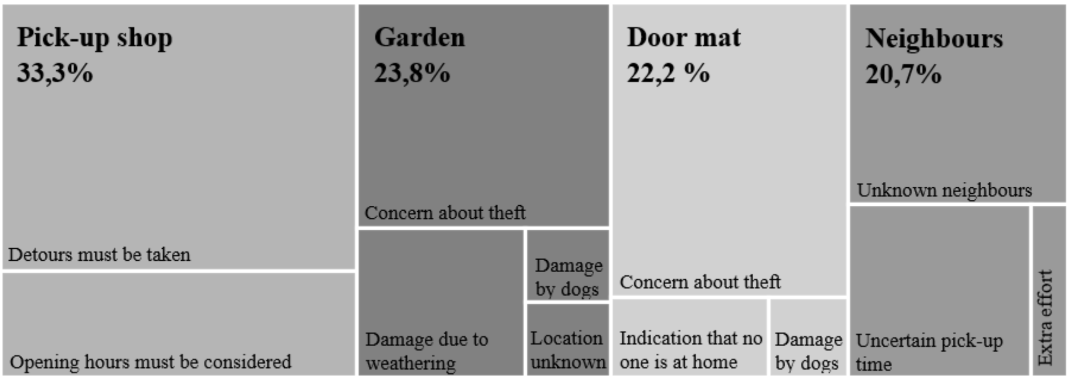

Fig. 5: Reasons for the undesirable deposit locations (online survey May/June 2020)

5.2 Analysis of delivery times at the target areas

The analysis of delivery and pick-up times is based on the quantitative usage data, which is permanently and automatically recorded by the white-label parcel locker system. Figure 6 clearly shows that the delivery of parcels by the CEP service takes place in very different periods than the collection of parcels from the white-label parcel lockers by the recipients. In Kaumberg, most deliveries are made between 08:00 and 10:00 in the morning and in Vienna between 11:00 and 13:00. The collection of the parcels by the customers, on the other hand, takes place in the afternoon or predominantly in the period between 17:00 and 20:00. Especially at the pilot location in Kaumberg, the parcels are also regularly collected until 22:00. A further evaluation shows that the distribution of delivery and collection regarding the days of the week is almost equally distributed at both pilot locations on weekdays and Saturdays. Only on Sundays and public holidays are there hardly any deliveries or collections.

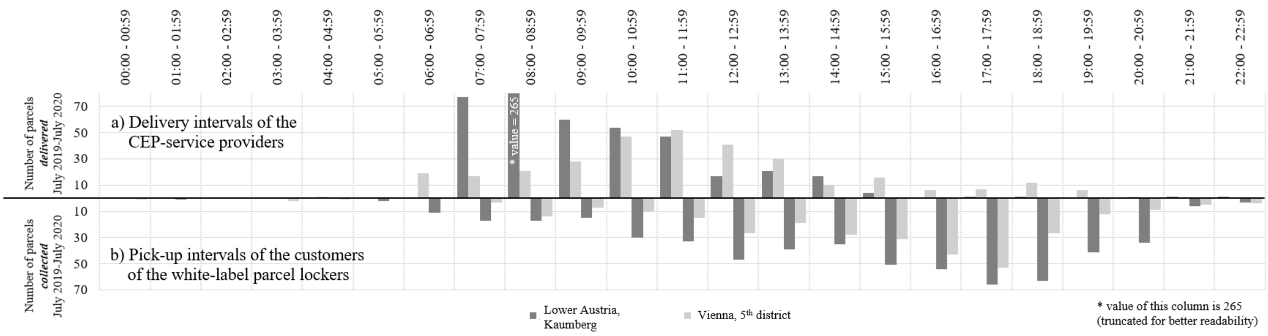

Fig. 6: Comparison of delivery (a) and pick-up (b) intervals at the pilot locations in the period July 2019 to July 2020

5.3 Analysis of the required detours to handle the delivery process at the target areas

The delivery situation without white-label parcel lockers leads to detours up to 15km, especially at the pilot location in Kaumberg. There the detours are covered by almost three-quarters of the people by car to pick up the parcel from a parcel shop. Furthermore, the pick-up is strongly restricted by the given opening hours, which causes a significant delay in receiving the parcel. In the catchment area of the pilot location in Vienna Margareten, the detours in kilometres are less decisive, but rather the additional time required for the recipients when a parcel has to be collected from a parcel shop.

Especially the results of the online survey from May/June 2020 shows that the distance to the nearest parcel shop from the respondents' homes is an important distinguishing feature of the catchment areas. In the area of Vienna Margareten, 55% of the respondents stated that the nearest parcel shop was within 500m of their place of residence and that they did not have to make a detour of more than 5km. Whereas in Kaumberg, the nearest parcel shop is 1 to 5 km away from the recipients' homes for 57%, and 14% have to travel more than 10 km to reach the parcel shop.

When considering the detours that are required to pick up a parcel from the parcel shop, this amounts to an average of 7 minutes in Kaumberg. On the other hand, in Vienna, the average detours take 17 minutes and over 90% of the people walk and none of the survey participants goes by car.

With the option of delivering a parcel via white-label parcel lockers, the diversions in minutes to pick up a parcel is reduced at both pilot locations. In Kaumberg, the average detour is reduced to about three minutes and in Vienna to less than one minute, as the parcel wall is located in the respondents' homes.

Furthermore, the information on the forms of mobility predominantly chosen for collection in the Vienna catchment area changes to a lower proportion of walking and the omission of public transport. As a result, the car is increasingly used. This may be because no extra detours have to be made, but the white-label parcel locker is on the way to work, for example, and no other walk is required. For the catchment area of Kaumberg, it is true that at the loss of mobility by car, parcels are picked up on foot about 10% more often. At the same time, the total time spent is reduced significantly.

5.4 Parcel volume during pilot operation

In contrast to the number of registered persons, only about 56% used the white-label parcel lockers as a delivery option. At the location in Vienna, 17 active users can be recorded, who had an average of 18 parcels per person delivered via the WLP from July 2019 to July 2020. This means an average value of 4.7 parcels delivered per month for the most active user and an overall average of 1.4 parcels per month per active user at the WLP location in Vienna Margareten.

At the pilot location in Kaumberg, Lower Austria, a total of 25 people used the parcel wall as a delivery option at least once in the period from July 2019 to July 2020. With 22.8 parcels per active customer, a higher average value was achieved than at the pilot location in Vienna. The maximum value of 88 parcels delivered for this registered person means that an average of 6.7 parcels per month were delivered via the white-label parcel lockers from July 2019-July 2020. Overall, an average of 1.7 parcels per month per registered person is achieved at the Kaumberg Lower Austria site in the period July 2019 to July 2020 inclusive. It must be emphasised that the median for both pilot locations is 15 parcels per active customer within the period of one year, if the outliers with over 60 parcels per year are eliminated.

The chronological analysis of the delivered parcels per month from July 2019 to July 2020 shows the highest delivery rates in October, November and December 2019 (Figure 7). At this point, it should be noted that since November 2019, the number of registered customers has remained almost constant at approximately 70 people. A further increase in the number of parcels delivered via the white-label parcel lockers occurred at both pilot sites in March and April 2020. This period was particularly affected by the Covid-19 pandemic and the associated restrictions on local trade due to the Austrian federal government's lockdown measures. The strong increase in delivery amounts in September 2019 at the Vienna location is due to the equal increase in newly registered customers in this month.

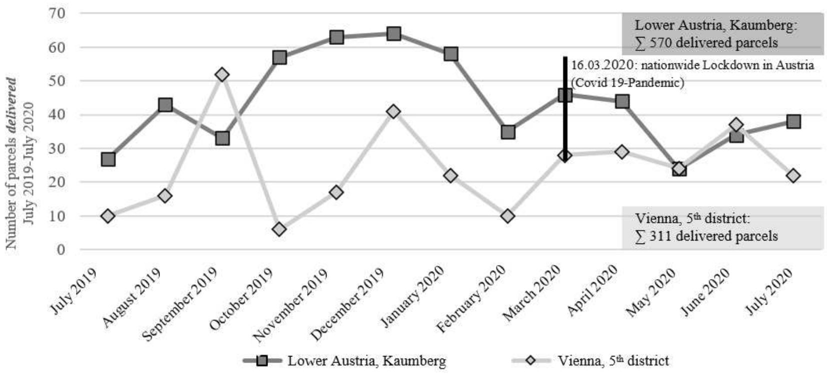

Fig. 7: Number of delivered parcels per month via the white-label parcel lockers in the perios July 2019-July 2020

5.5 Usage and ordering behaviour of participants in the target areas

In order to evaluate the usage and ordering behaviour, various situations were assessed by the customers on a scale from "strongly disagree" to "strongly agree". Almost 80% of the participants from the Kaumberg catchment area stated, both at the workshop in October 2019 and in the online survey in May/June 2020, that the white-label parcel lockers have no negative influence on the local suppliers and small shops/service providers in the municipality. All participants can reduce the time and distance spent compared to the delivery situation without white-label parcel lockers. For the Vienna location, the result is similar, but significantly more people (almost 40%) stated that substituting local shopping due to the white-label parcel-lockers is not out of the question. The possibility of making deliveries via the white-label parcel lockers prompts most of the participants to order more items online. The range of product groups ordered online is also expanding to include product categories that tend to be more expensive, such as computers and car accessories as well as electronic items. The Sankey diagram in Figure 8 shows how delivery frequencies per category have changed, indicating that in most cases the change per person tends towards a more frequent delivery number per unit of time.

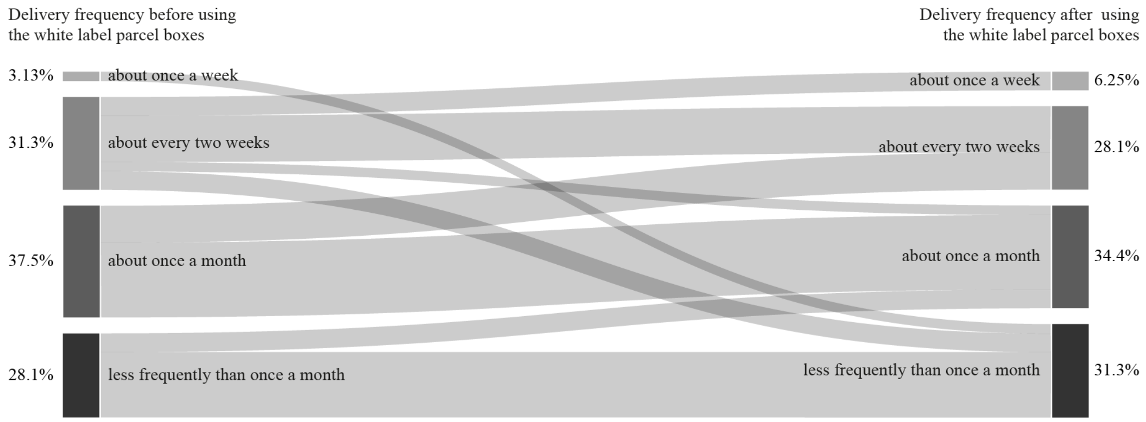

Fig. 8: Frequency of deliveries by CEP services before and after the possibility to receive orders via the white-label parcel lockers (online survey May/June 2020)

5.6 SWOT-Analysis of the white-label parcel lockers

In order to assess the strengths, weaknesses, opportunities and threats of the WLP, interviews with people from different stakeholder groups were conducted in addition to the surveys and workshops related to the pilot operation. The resulting findings are summarised in a SWOT analysis (Figure 9). SWOT refers to the fields of action Strengths - Weaknesses- Opportunities - Threats. (Krogerus et al. 2017).

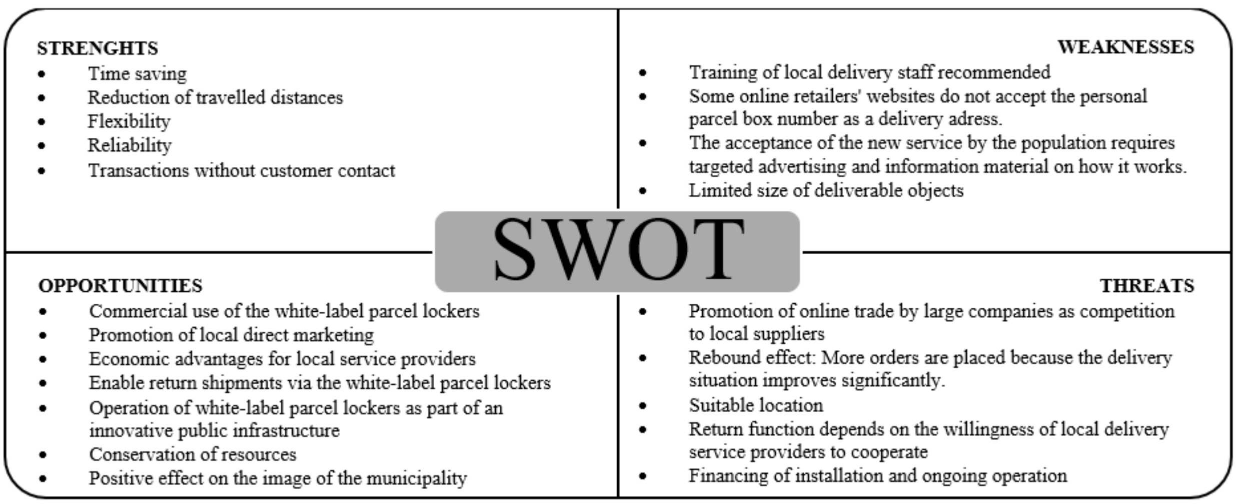

Fig. 9: SWOT analysis of the white-label parcel lockers

For example, more than half of the CEP drivers surveyed, see the use of parcel lockers as a very positive alternative to traditional door/mailbox delivery. Mainly due to the possibility leaving parcels at any time and thus process them faster. Especially for entrepreneurs, the handling of transactions without customer contact and at any time represents a very high added value. By using the WLP as a delivery option, hardly any negative effects can be identified by the customers surveyed.

The interviews with functionaries of the municipal administration and experts of the economy and regional development refer to the economic situation, business landscape, and spatial structure of the municipality. Further, the effects on residents, the environment, traffic and local businesses are discussed. Based on the interviews it is critically pointed out that white-label parcel lockers have to be used carefully so that they do not represent additional competition to the local retail trade. Regarding to the achievable economic added value in the supply chain, it is noted that this requires intensive cooperation with the companies in the catchment areas. In addition, the price/performance ratio must be acceptable to the entrepreneurs. If these factors are met, an increase in the competitiveness of local businesses compared to online business is possible. Finding a suitable location involves a risk and should consider the local scene and cityscape. An opportunity for long-term independent operation is seen primarily in operating the white-label parcel lockers as part of the municipalities' public infrastructure. However, this would require financial support from the municipalities, especially in the course of installation.

Further it is essential for the implementation that the system is easily manageable and easy to use for all groups of people. Customer service must be permanently available to prevent frustration in case of problems. The development of a service for the last mile between the white-label parcel lockers and the residence for people with limited mobility would be desirable. Standards and regulations are necessary for a uniformly functioning system. Finally, the success of the system depends on the commitment of the municipal administration and the active cooperation with local stakeholders.

6 CONCLUSIONS

The pilot operation in the target areas of Kaumberg Lower Austria and Vienna Margareten lasted twelve months from July 2019 to July 2020. In this period the core services delivery of parcels, deposit of parcels C2C and deposit of parcels B2C could be tested free of charge by participants from the catchment areas. A total of 74 people registered during the pilot operation, of which 17 persons were identified as active users at the Vienna Margareten location and 25 at the Kaumberg Lower Austria location. The total number of successfully delivered parcels during this period was 881. Several surveys show that the greatest advantage of white-label parcel lockers is seen in the independence of parcel delivery. Therefore, the delivery reliability and efficiency can be significantly increased. At the same time, a reduction in energy consumption, savings in time and travel costs as well as a reduction in traffic-induced CO2 emissions can be achieved at both pilot locations by shortening the transport routes.

7 FUTURE WORK

The sustainable success of white-label parcel lockers depends on a variety of factors. Identifying these factors and linking them to existing data could enable optimal location decisions using machine learning or AI (artificial intelligence). It is already clear from alBox that location plays a key role in the economic and environmental savings potential. An analysis of alternative forms of financing (keyword PPP) could show a way to enable innovative logistics infrastructure, especially in rural areas. Possible commercial potentials need to be surveyed in order to investigate the economic viability of different locations.

8 ACKNOWLEDGEMENTS

This work has been partially funded by the Klima- und Energiefonds, in the “Smart Cities Demo - Living Urban Innovation 2018” programme under grant number 872094 (“inned”). The authors would like to thank all project partners for valuable feedback and their input as well as the consulted experts for sharing their views regarding the impact.

1 ABSTRACT

In the context of the Fourth Industrial Revolution, the world of architecture and construction is being changed by new technologies with opportunities and limitations. Large-scale 3D printing (3DP) technology has recently been introduced as a new building technology to improve productivity and quality. Recently, worldwide stakeholders started experimenting with the technology substitute of traditional. This is due to achieve potentials benefits, such as increased accuracy, customisation, and design flexibility. Additionally, it reduces wasted material, costs, manpower, and printing time. However, these initial investigations are very fragmented at the time of the study. There are different views on where technology can be directed and a large gap between ideas and their applications. 3D printers will be used primarily to print buildings for low-income housing and emergency housing in developing countries such as Egypt, while most of the buildings that have been built were executed in developed countries. Therefore, it is necessary to understand the international applications and challenges of 3D printing. This paper was set out to give insight into applying 3D printing as a new building technology on an international scale and assessing the applicability potentials and challenges in the Egyptian context; through 1. gathering and analysis of documents and references of opportunities and limitations of 3D printing factors(design, environmental, social, and economical); 2. qualitative data analysis.The descriptive study of international examples outlines the factors used to assess the international examples with anassessment matrix and analysethem within the Egyptian context. It shows that projects divide internationally into projects which invest in optimising the performance and others which are optimising the production according to different characterisations. There are greatpotentials of using 3D printing in Egypt, but it needs to be adapted to numerous challenges in achievingits maximum potential.

Keywords: 3D Printing, Building technology, Architecture, construction, Egyptian context.

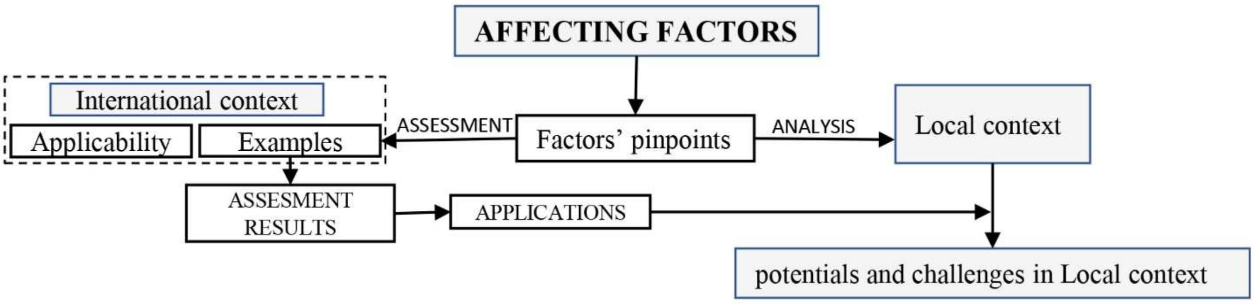

Fig 1The research flowchart

2 INTRODUCTION

The world is confronted with many challenges that have the potential to impact the well-being of societies severely. Climate change, rapid urbanisation, and the digital revolution are among the most pressing of these challenges(Renz et al., 2016). The creation of sustainable, cheap, durable, customisable, recyclable, and even environmentally reparable houses is a critical focus of recent research.The new wave of marketneedsduring the current crisis requiresasustainable economic approach to saving energy which will reduce the cost of housing and improve the quality of continuous production(Wu & Wang, 2016). Regarding the many social issues that must be considered. Fear of job loss is the main problem (De Schutter et al., 2018).

The construction sector plays a key role in any country's economy. According to a report published by the World Economic Forum, the construction industry currently accountsfor 6.2% of Egypt's GDP,and a 1 % increase in productivity around the world could save a lot in construction costs (Forum, 2018). "The promise of large-scale 3D printing (3DP) is that it can collapse these limitations, which is a fundamental shift in the relationship between architecture, construction, and manufacturing"(Hager, Golonka, & Putanowicz, 2016).

In Egypt, the traditional and most common way of building is witha load-bearing structure and a skeleton framework which requires transport of heavy materials (bricks, cement, sand, and aggregate) to the construction site where on-site wall construction is done with mixed concrete components and manual bricklaying. This approach results in the use of a large number of workers, a lengthy procedure, a high percentage of errors, waste of materials, unnecessary expense, and CO2 emissions resulting from long-distance transportation.

3 AFFECTING FACTORS IN APPLYING 3D PRINTING

3DP technology offers many opportunities for architecture and the construction sector, but also has limitations which determine its actual implementation in many aspects, concerning design, environmental, social and economic factors (Ma, Wang, & Ju, 2018; SKÖLD & VIDARSSON, 2015; Yeh & Chen, 2018).

	Opportunities	Limitations
Design-Related Factors	Production of specialised moulds (Camacho et al., 2018).	Conventional design approaches are not suitable for printing.
	3D printing technology will push design to change(SKÖLD & VIDARSSON, 2015).	The size of the built object is limited by a gantry or cable-suspended approaches
	It can also help build "smart structures" which include various properties(Camacho et al., 2018).	The building elements, doors windows, pipe systems, wires, and horizontal components were prefabricated and considered to reduce the absolute free flexibility in mass customisation.
	Complex geometries without a tool and less waste material(Camacho et al., 2018).	
	Improving the quality and reliability of elements by eliminating human errors.	Buildings today are limited to producing concrete-based load-bearing components.
Environmental-Related Factors	Some benefits of this technology can helpin adapt and mitigate climate change (Ding, 2008).	Limitation in material flexibility means that only specific material can move through a machine and can still be used in the desired manner without damaging or deforming the specific machine (Perkins & Skitmore, 2015).
	3D printing uses a significantly smaller amount of building materials than conventional buildings.	
	Reducing formwork, and waste material, (Camacho et al., 2018).	
	Decreasing the use of raw materials and removal and recycling from sites(De Schutter et al., 2018).	
	Using reused or recycled or rapidly renewable materials (De Laubier, Wunder, Witthöft, & Rothballer, 2018).	
	Decreases the emission rate of CO2 (De Schutter et al., 2018).	
	3D printing works on electricity and saving large quantities of fuel (Perkins & Skitmore, 2015).	
Social-Related Factors	Reduce the demand for professional craft while opening up new possibilities for the workforce with various skills (Camacho et al., 2018).	One great fear of a rise in the concept of automation is that workers will lose their jobs (De Schutter et al., 2018).
	Reducing exposure to harsh environments, reducing accident rates (Camacho et al., 2018).	Deal with many organisational and managerial obstacles (Yeh & Chen, 2018).
	Add more specialised suppliers (changing in the supply chain) (SKÖLD & VIDARSSON, 2015).	Directly influence already existing customers and suppliers (SKÖLD & VIDARSSON, 2015).
	For customers, 3DP. Allows end-users to adapt their house design to their own needs.	The adoption of 3DP. Was hampered by bureaucratic factors (De Laubier et al., 2018).
	For a new generation, completely new jobs that do not currently exist when they enter employment in the future.	The construction sector is one of the most conservative fields which is slowly changing and adapting with a new technology
Economics-Related Factors	Over the years, the cost of 3DP has decreased considerably (Perkins & Skitmore, 2015).	Economic unattractiveness of expensive automated equipment.
	3DP is cost-effective when it comes to a custom product with a complex form (De Schutter et al., 2018).	The unsuitability of the available automated fabrication technologies for large-scale products.
	3SP can manufacture complex geometries without additional cost (De Schutter et al., 2018).	Requires significant start-up costs and specially trained operators (Perkins & Skitmore, 2015).
	3DP decreases service staff costs (transport, accommodation, taxes, etc.)(Camacho et al., 2018)	The costs of machines arebased on print speed as well as material (Yeh & Chen, 2018).
	There is no waste or waste requiring removal and recycling from building sites (Camacho et al., 2018).	High initial costs for equipment and ongoing maintenance costs (Perkins & Skitmore, 2015).
	Reducing formwork labour costs, temporary moulding, and material costs from 35-60% of the total cost (Camacho et al., 2018).	The building elements, doors, pipe systems, and horizontal components which were prefabricated to fit custom products will increase the cost.
	The system as a whole will be capable of reducing construction costs by close to 30 % (Perkins & Skitmore, 2015).	The software packages would increase the cost (Perkins & Skitmore, 2015).
	Adding additional value (e.g., flexibility and scalability, mass customisation, thermal insulation, materials reduction, and time reduction) at no additional cost. (Camacho et al., 2018; Lim et al., 2012; Perkins & Skitmore, 2015).	In addition, automated systems operating on dirty worksites outdoors would need frequent cleaning and maintenance downtime (Perkins & Skitmore, 2015).

Table 1 Opportunities and limitations of affecting factors.(sources are cited for each point)

4 METHODS

Firstly, analysis and overview of documents for international applicability to determine the spread worldwide; secondly,descriptive study of international examples.

Fig 2 The world map showing international 3DP examples: countries which developed and export technology countries which import technology, develop and adopt it, countries which import technology (Compiled by the authors, sources are cited for each example)

TECLA habitat, Italy	YHNOVA H., France	Winsun projects, China	Residential H., Russia
On-site –2019 WASP	On-site - 2017 Batiprint3d	Off-site - 2014 Winsuns 3DP.	On-Site -2016 3DP.: Apis Cor
Clay (mould) + bio-materials	Polyurethane (mould) + concrete	Concrete with glass fibre	Concrete material
The circular housing model, created using entirely local reusable, recyclable materials moving towards eco-housing, designed to be resilient to any climate and energy-efficient (Chiusoli, 2019).	It improved the energy performance of construction, and with its zero waste, raw materials, and decreased transport, the project's ecological footprint was lowered (Furet, Poullain, & Garnier, 2019).	The highest 3DP building was prefabricated elements and assembled on a site. 10 houses in Shanghai, Winsun reduces the overall construction time by 50% to 70%, labour by 50% to 80%, and materials by 30% to 60% (Hager et al., 2016).	Ease of transporting systems, Only two people are required for operation and material supply, less time just 24 hours minimise human errors, It consumes only 8 kW of power, and The cost of the building is $10,000 (Craveiroa et al., 2019).

1. AMIE, USA	2. DFAB H., Switzerland	3. Grotesque – Switzerland	4. Fluid Morphology, Germany
Off-site -2015 Ornl'sBaam	Off-site 2019 3D Sand P.	From 2013 3D sandstone	Off-site - 2020 3DP Delta Towe
Steel rods + glazed materials	Concrete material	Sandstone material	Polycarbonate material
Many functions of a conventional wall system structure, insulation, moisture barriers, and cladding. This could lead to zero-waste construction, reduced material (Craveiroa et al., 2019).	An 80 m² lightweight concrete floor slab as part of the House, its highly complex structures are as easy to create as a solid block. In addition, time on site was reduced (Redaktion, 2018).	The computer was a partner in design who proposed an endless number of permutations. This highly ornamental structure is designed entirely by algorithms (Dillenburger, 2017).	The facade is divided into panels, each measuring 1 m². While textural waves and bulges create shadows. Thin integrated tubes allow air circulation from one side to the other, ensuring the best ventilation (barandy, 2019).
5. Future Office,UAE	6. Multi-use B., UAE	7. 3DP. Village, Mexico	8. 3DP. House, Saudi Arabia
Off-site 2016 Winsun3DP. (china)	On-site-2019 Apis Cor (USA)	On-site -2017 ICON's 3DP. USA	On-site2018 Cybe (Netherlands)
(SRC), (FRP), and (GRG)	Concrete and gypsum	Cement mixture	Cement mixture
Fully functional building featuring electricity, water, and systems. It took 17 days in China and was shipped and installed in 2 days. It reduced labour costs by 50 % to 80% and construction waste by 30% to 60% (Craveiroa et al., 2019).	Apis Cor developed a gypsum-based material to run through the printer, which was sourced for a local producer. Reduction in labour and, therefore, reduction in cost (Molitch-Hou, 2020).	In a remote area in Mexico, The printer has been created as a solution to minimise homelessness that caters to the ever-changing social housing sector and housing crisis (Grace, 2019).	Invest in advantages in construction sites from Cost and standardisation of quality, waste minimisation, speed of implementation, reduction of work accidents, and the possibility of implementing forms (MinistryofHousing, 2018).

Table 2: selected International Examples (Project name, on-site or off-site, 3d printer name, material, description, and source)

4.1 International Applicability Overview

The analysis of the international spread of 3DP indicates that there are three categories of countries (as shown in figure 1) that deal with 3DP. Firstly, Countries that developed the machine concept, process, and materialsand are exporting 3D, such as the USA,Netherlands,UK, Italy, Switzerland, Russia, Germany, Slovenia, China, France, Denmark, Australia, Spain, and Belgium (barandy, 2019; Camacho et al., 2018; cobod, 2019; Craveiroa, Duartec, Bartoloa, & Bartolod, 2019; De Laubier et al., 2018; Valdivieso, 2019).Secondly, countries which import technology, are adapting it andseeking to invest in other experiences with local requirements such as the Philippines from the USA, Thailand from Italy, UAE from USA(Camacho et al., 2018; Craveiroa et al., 2019; De Laubier et al., 2018).Thirdly, countries which import technology, such as Saudi Arabia from China, Morocco from Spain, Mexico, and El Salvador from the USA, and Malawi from Denmark(3dprint, 2020; De Laubier et al., 2018; Valdivieso, 2019; worldeconomicforum, 2019).

Previous cases show that many countries were involved in developing 3DP technology and materials usedfor it. 3DP technology is capturing increasing international attention in the building technology field. As shown in fig 2, the technology is distributed all over the world, in developed and developing countries.

4.2 InternationalExamples

To date, there have been many experiments in the field of architecture and construction spread across the world, as shown in Fig 2 regarding mainly the construction of whole (small) buildings with materials such as concrete, bioplastic, and clay, also, manufacturing Elements and Details. 12 international Examples were selected to study aspects based on differences in the project approach.

Fig 3 Selected international Examples (Compiled by the Researcher, Sources are cited for each Examples)

5 RESULTS

The results are divided into three sections. Firstly, outlining the key factors based on the analysis of the opportunities and limitations of affecting factors. Secondly, assessing the strength of the factors of each example with an assessment matrix and thirdly, analysing the characteristics of the affecting factors in the Egyptian context.

5.1 Key affecting factors

Outline of the keyfactors derived from the opportunities and limitations of affecting factors in part 3.

Design Related Factors	Environmental Related Factors	Social Related Factors	EconomicsRelated Factors
Design flexibility Structure functionality Design optimisation Quality issues	Climate change adaptation Lower resources Materials Reduced materials Raw materials Reused or recycled Decreasing the emission of CO2 Less total energy	Reducing workforce Jobs shifting paradigm Safety in extreme environments Fewer accidents rate New job opportunities	Initial cost Reducing materials cost Reducing labour cost Cost reducing Unique architecture Mass customisation Time-saving

Table 3: Affecting factors' pinpoints(by authors derived from part 3)

5.2 Assessment Matrix of Selected Examples

Assessment of the strong points of each example measured by achieving factors at three levels: fully present, partially present, and does not exist as shown in fig 4.

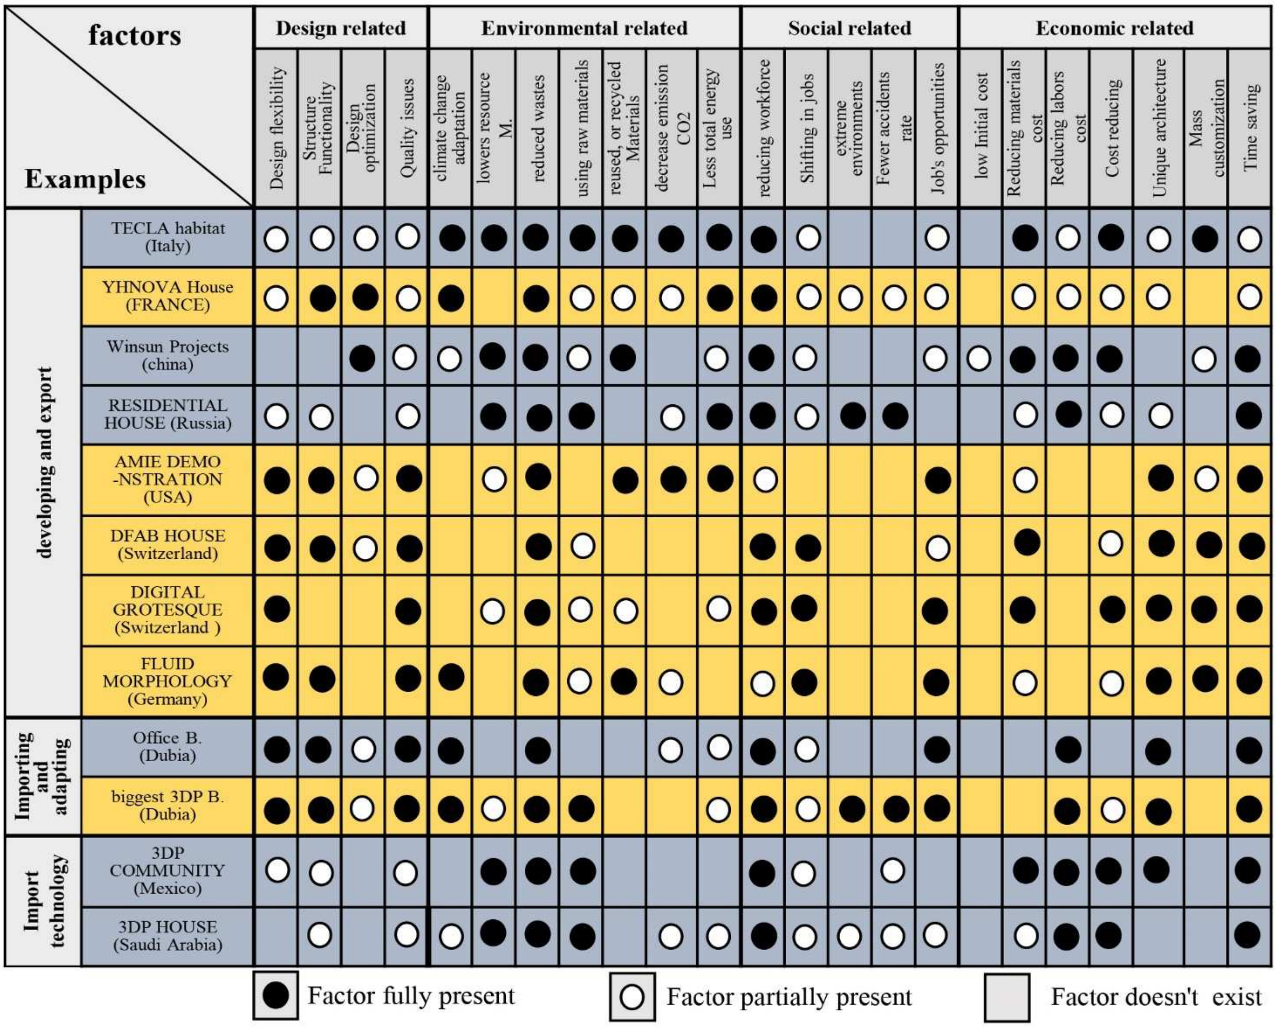

Fig. 4: Assessment matrix for selected international Examples(by authors)

5.3 Analysis of Assessment Matrix

Regarding the strategy of using 3DP, there are two main approaches in the studiedexamples. Optimising the performance, and optimising the production. The former aims to develophigh-performance by analysing the design-related factors and environmental-related factors of printable materials, methods to print unique architecture with structurally optimised shapes; overall,it aimsto achievethe highest possible quality,full customisability both of shape and printed material, and structure functionality. The latter aims at optimising the production, developing technology by considering mainly the economic and environmental-related factors, such as low cost, fast but customised alternativesof traditional construction itwould aim at using local, cheap materials and optimising the construction method in terms of cost and speed. Printing would occur locally (either on- or off-site). Based on the above analysis, the selected examples can be divided into two groups, as shown in table 4.

Examples of Optimising the Performance		Examples of Optimising the Production,	
YHNOVA H., France	Grotesque – Switzerland	TECLA habitat, Italy	Multi-use B., UAE
AMIE, USA	Fluid Morphology, Germany	Winsun projects, China	3DP. Village, Mexico
DFAB H., Switzerland	Future Office, UAE	Residential H., Russia	3DP. House, Saudi Arabia

Table 4: classification of the selected examples(by authors).

The assessment matrix is converted into a visual percentage chart divided into performance and production groups (each group has 6 examples). according to the three levels of assessment: does not exist = 0 X, partially present = 1 X, and fully present = 2 X (whereas X is a fixed number). therefore, every criterionis assessed in 12 X for each group; i.e., the first criterion is the design flexibility in the performance group from the matrix (5 fully present + 1 partially present = 10 X + 1 X = 11 X) therefore, 11 X * 100 / 12 X = 91.7 %, and so on.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

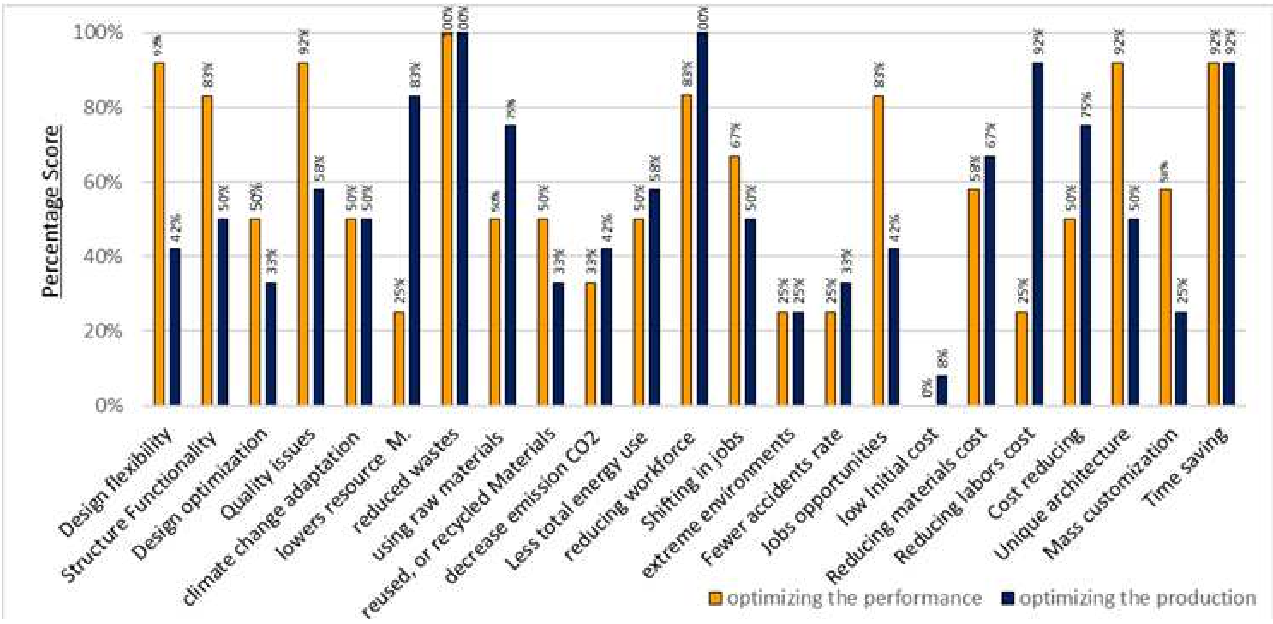

Fig 5: percentage score of assessment criteria in selected examples based on optimizing the performance or the production(by authors).

Although there are still only a few examples around the world, it could be concluded that significant strengthsare found in most of the examples, whether optimising the performance or the production (fig 4): reducing waste in resources and materials, saving time, and reducing the workforce.

The examples of optimising the performance are characterised by:

- Novel forms of design flexibility, a range of customisations and complexity,
- Optimised typology and functionality with high accuracy and quality,
- Developing new applications with new job opportunities,
- Developing a variety of materials, machine layouts, and properties.

On the other hand, the examples of optimising the production are characterised by:

- Mass production buildings by reducing cost and construction time,
- Using in situ resources, reducing material transportation costs and sustainable design solutions,
- Increased accessibility,reduced risks in remote sites and extreme environments.

5.4 Analysis of affecting factors characteristics within the Egyptiancontext

The analysis of the characteristics of the affecting factors within the Egyptian context aimed to determine the potentials and challenges in applying 3D printing in Egypt.

In addition, the construction sector is one of the most conservative fields in Egypt, where building technology development depends on the shareholders who are involved in the current value chain and are avoiding change. Also, regulatory policies have strong technological influences on regulations and building codes. Hampered by bureaucratic factors, integrating new technology into the construction process,which is considered very conservative in changing or development, is very slow. Besides that, there are mainly technological limitations, such as the size of the built object, limited by gantry which determines the options of applicability in Egypt regarding low-rise buildings (ground to ground and two levels), and to the fact that only specific material can move through a 3D printing machine.

Factor	Sub-factor	Characteristics of 3DP factors	The case of Egypt
Design-related F.		Design flexibility Pushing design to change and restrictingregular designs.	As a result of the rapid urbanisation in Egypt, architectural design tends to be more practical and economical. While the architectural flexibility of 3DP technology may push designers to pay attention to environmental considerations and heritage styles.
Design-related F.		Structurefunctionality Building "smart structures".	Opportunity for materials technology. Research &development of printable materials developed locally. Such as desert sand, to add new features suitable for this process.
Design-related F.		Design optimisation Producing specialised molds.	Opportunity to provide flexibility in architectural design, which does not require a standardisation of production elements, saving materials and time.
Design-related F.		Quality issues Increase the execution accuracy.	Egypt is at a medium level of quality due to the size and quality of the workforce, but mistakes are increasing the cost due tothe need for corrections.
Environmental-		Climatechange adaptionand mitigation	The new technology supports thermal mitigation such as wall thickness, the amount of air in the wall section
Environmental-		Fewerresources.	Positive effects to save the natural resources which are the primary source for buildings.
Environmental-		Reducing material waste.	Material waste of timber frameworks averages 13%, and waste of sand is as high as 9% (Garas, Anis, & El Gammal).
Environmental-		Using raw, reused materials	Egypt has many local raw materials suitable for construction, such as sand and clay
Environmental-		Decreases the emission rate of CO_2 remarkable.	Egypt produced 310 m tonnes of CO_2 greenhouse gas emissions in 2016. Thus any reduction in fuel use will be a positive impact (Hannah Ritchie, 2020).
Environmental-		Fewerfossil fuel energyto produce electricity.	This is consistent with Egypt's Vision 2030 to use clean energy instead of fossil fuels.
Social-related F.		Reducing workforce Workers will lose their jobs	This is a threat in Egypt. The construction sector is providing around 3.7 million jobs, representing 20 percent of total workers in the domestic market(according to Planning Minister Hala al-Saeed), although it does not create sustainable or stable jobs, as it is linked to project time (EgyptToday, 2018).
Social-related F.	Jobsshifting	Add more value to the construction phase	It will affect the construction industry, technically, economically, and socially, resulting in the entry of new producers, processors, suppliers, and exporters.
Social-related F.	Jobsshifting	Changing roles and organisational processes.	Using 3D printing In Egypt shortensmany building processes (e.g., design, coding details, training, manufacturing,and marketing).
Social-related F.	Jobsshifting	Impact on supply chain	Using new technology will negatively affect the traditional suppliers in Egypt.
Social-related F.		Reducing exposure to harsh environments.	May be useful in difficult worksite conditions in Egypt, such as the extremely hot desert climate.
Social-related F.		Loweraccident rate Safety in the construction sector, fewer accidents	Alarming statistics indicate that the construction industry accounts for 55,000 fatal injuries each year in Egypt and the construction industry has the highest fatalities and death rates among all industries (ElSafty, ElSafty, & Malek, 2012).
Social-related F.		New job opportunities Reducing the demand for the professional craft.	The traditional labour market has a large number of untrained workers (who do not have a job and work in construction), leading to a shortage of skilled workers, but using 3DP would move technical construction jobs to new opportunities of dealing with technology.
Economics-related F.		High Initial Cost The costs of machines, Specially trained operators, The software packages, Special material types.	Printing technology, like anything new, starts expensive, but over time it is getting more affordable. A machine is a one-time investment that should pay for itself over time replacing computing and healthcare costs. However, the machine cost ranges from 80 000 \$ to 500 000 \$ (Cherdo, 2020), an investment which s the construction market in Egypt would have to bear.
Economics-related F.	ls cost	Reducing materials cost (fewer materials are needed). Reducing waste requiring removal and recycling from building sites.	According to (ECBM),Egypt's exports of building materials, refractory and metallurgy industries was \$1.5 billion during the first quarter of 2020, an increase of 32.8 percent, compared to \$1.15 billion a year earlier.Research indicates that using printing saves between 30% to 70% in materials, which will positively impact the Egyptian economy (egypttoday, 2020).
Economics-related F.		Reducing labour cost (reduces the number and service)	Saving labour costs, transportation, insurance, and health expenses is an economic advantage, especially during a health crises.
Economics-related F.		Reducing construction costs	TheEgyptian construction sector performed strongly during FY 2019, contributing 6.2% to Egypt's GDP. Therefore, any saving in the cost will have a good impact on the economy.
Economics-related F.		Time-savingdue to printers' ability to operate 24/7	Avoiding delays related to deliveries and coordination caused by working requirements for installing utilities will be more cost-effective. One of the main reasons for the high construction cost is delays during the execution period in Egypt.
Economics-related F.		Adding additional value at no additional cost Design flexibility Complex geometries Mass customisation, Thermal insulation, Time reduction.	Value relates to assessing the benefits brought by something regarding the resources needed to achieve it, whichin the case of 3D printing includes design, production, and environmental response, and reducing time without additional cost. In Egypt, using 3DP as new technology is itself consideredto add value.

Table 5: Analysis of the characteristics of the affecting factors in the Egyptian context (by authors)

6 DISCUSSION

This section addresses several points. The international adaptability, Accordingly part 4, countries are divided into three categories. Those which develop and export 3DP technology and consider mainly developed countries are focusing on developing new materials, new applications, restoration and refurbishment, as an alternative method to solve the labour shortage problem in many developed countries, and ultimatelyon exporting3DP to developing countries as commercial technology. The second group of countries import technology andadapt it by developing machine properties and suitable materials to match the local requirements, while the third group of countries imports technology and focuses on affordability by reducing construction cost and time.

Although the selected examples studied are characterized by diversity in applied approaches and the materials used.However, the technology clearly shows that. It is still in the light of experiments and exploration, not consumer technology. Also, the printer's limitations in print just the foundations and entire building walls, but did not include printing other components and need special covering most constructive sites.

Regarding the strategy of using 3DP in international applications, the study found two main approaches among the examples: optimising performance and optimising production. It could be concluded that The application of 3D printing technology can bring many benefits, such as reducing waste of resources and materials, saving time, and reducing the workforce. The approach of optimising performance is characterised by novel forms of design flexibility, typology optimising and functionality, development of new applications, new materials, and machine layout. The approach of optimising production is characterised by mass production, using in situ resources, and increased accessibility which could mainly be used for affordable housing.

There are distinct international experiences that can be investigated in the Egyptian context, whether concern with optimizing the performance and optimizing the production. The following table determines the strength points which be Applicable in Egypt from different international Examples based on the assessment results.

	characterised points	International Examples		Applicable in Egypt
Optimising the Performance	Novel Forms and Design Flexibility	Future Office in UAE, CURVE APPEAL in the USA,	Applications	full or partial free form or luxury buildings,
		DFAB H. in Switzerland		Interiors-designed elements.
	Typology Optimising and Functionality,	Fluid Morphology in Germany		Architectural cladding Adaptable, portable units
	Develop New Application	Digital Grotesque in Switzerland		Print accurate details as Repairing or reproducing historical structure.
	Develop A Variety of Materials. Develop Machine Layout and Properties.	YHNOVA House in France (Polyurethane mold)	Materials	Salt as a raw material GFRC as Permanent formwork GFRP as a wireframe Bioplastic, Spray-foam as a mold Nylon as a light structure
Optimising the Production	Mass Production Concept	Winsun projects 3DP village, Mexico	Applications	affordability housing, prefabrication Building elements, Emergency shelters.
	Increased Accessibility, Reduced Risks in Remote Site	Residential House in Russia		Remote or hazard construction site, Rapid structure for military purposes.
	In-Situ Resources and Local Materials	TECLA habitat in Italy (Clay as a mold) + bio-materials (husks and rice straw) Multi-use Building in the UAE (concrete and gypsum).	Materials	Sand as a construction material Concrete reinforced by, fly ash, silica fume, and nano-silica. Clay is a ceramic material. Glass-fibre-reinforced gypsum (GFRG)

Table 6: Applicable of applications and materials in Egypt (by authors)

According to the available materials suitable for use with 3D printing In Egypt, there are opportunities to use local materials such as sand with admixtures, concrete with additives (such as flash ash, Silica fume, and nano-silica), clay, and salt.

Table 6 provides a synthesis of the outcome of the research; it lists the proposed applications of 3D printing in the construction sector derived from the analysis of selected international examples, it identifies the key characteristics of 3D printing in the field of construction, and it shows the impacts of 3DP as potentials and challenges in the Egyptian context.

Proposed Applications	Key factors	Potentials in Egypt context	Challenges in Egypt context
Full or partial free form or luxury buildings	Design Related Factors Design flexibility Structure functionality Design optimisation Quality issues Environmental Related Factors Climate change adaptation Lower resources materials Reduced materials Raw materials Reused, or recycled materials Decreasing CO2 emissions Less total energy use Social Related Factors Reducing workforce Shifting in jobs paradigm Safety in extreme environments Loweraccidents rates New job opportunities Economics Related Factors Initial cost Reducing materials cost Reducing labour cost Reducing overall costs Unique architecture Mass customisation Time-saving	Taking advantage of the mass customisation design, environmental benefits, and construction speed through materials development such as local sand, GFRC, GFRP, GFRG, biomaterials, and nanomaterials, in addition to the development ofa hyper-technical approach.	Supporting the private developers to afford the new technology, need of updating regulations and codes, lack of stakeholders' interest, dealing with shifting the supply chains, and construction workers'job paradigm
		Medium-term applicability–3DP could be applied projectsin the medium termfor luxury housing with limited floors, such as the future luxurious neighbourhoods in the Administrative Capital and the new al Alamein	
Interiors: designed elements Facade: cladding elements		Exploit reducing waste materials with design flexibility and accuracy without any additional cost. Materials could be used, such as GFRP, GFRC, and GFRG	Supporting small entrepreneurs and training designers to deal with the new design process and software
		High applicability inthe short term	
Adaptable portable units		3DP could be used for emergency medical shelters, to exploit mass production, andreduce constructiontime	The high initial cost and the benefit of speed must be a common application in use.
		Lowapplicability inthe long term	
Repairing or reproducing historical structures		Exploiting digital accuracy could be used to repair accurate details, reproduce a mesh with translucent materials in a historical building, live a new experience, compatibility with a 3D scanner for production of 3D model	Develop regulations and codes with new technology, develop 3D printer scale and machine layout, develop suitable materials, qualify professionals to manage it.
		High applicability in the short term	
Affordable housing		A new housing policy was being drafted to address the serious housing deficit; in the effort to provide affordable housing in a sustainable approach, so take advantages of in-site mass production, cost reduction (reduce wastes, workers costs) in long term,develop hyper technique approach, and using local materials such as desert sand, GFRC, GFRG, Clay, and concrete with fly ash, silica fume, and nano-silica. In addition, reducing the carbon footprint.	It's not suited in the Egyptian Urban context because of the limitations in the current 3DP., high cost of horizontal infrastructure, changes in the supply chain, shifting in workers Paradigm, update regulations and codes, overcome economic constraints, manage new technology risks, preparation in-site printing conditions,and the willingness of the lower and middle-income people to live in printed houses.
		Medium term applicability - It could be applied in the medium-term depending on the government and the private sector in providing affordable housing just in horizontal growth.	
Prefabricatedbuilding elements		Very similar to the construction on-site, except that it is characterised by greater accuracy, and controlling climate conditions.	Need of heavy transfer, disadvantages of fixtures and fittings, inflexible in design, need to qualify professionals to manage it.
		Lowapplicabilityinthe long term.	
Remote or hazardous construction sites		Replacing manual workforce with 3DP at remote and hazardous construction sites.thus reducing risks and labour costs and using raw materials such as sand.	Dealing with the problem of material properties at high temperatures condition
		High applicability inthe medium term	
Rapid structure for military purposes		Exploit construction speed and raw materials such as sand.	Manage new technology risks.
		Lowapplicabilityinthe medium term	

Table 7: potentials and challenges of applying proposed applications of 3DP in Egypt. (by authors)

It can be concluded that 3Dprinting is not a magical solution that can solve all the problems of traditional building techniques. Critical several challenges need to be resolved to achieve the maximum potential of the 3D printing technology, and many more potentials have to be investigated.

potentials	challenges
Increased design flexibility Time-saving Ability to use in-situ materials Variety of raw materials Reduced resources and material waste The environmentally way is to use demolition waste Cost reduction in addition to the minimised cost of storage and transportation cost of materials Reduced workforces and their transportation costs New lob opportunities as a new supplier Reduced health and safety risk on-site. Mass customisation at no extra cost.	3DP is reducing job opportunities for qualified workers. Materials of use for 3DP are limited as they require specific properties 3DP is not suitable for larger-scale projects Specific geometrical possibilities limit the printing method Utilities (electric, plumbing, and door and window) are not yet integrated into the design process Using 3DP also requires a change in the design process It is still a limited and expensive technology. There are no set regulations for using 3DP in construction Lack of knowledge about technology among the stakeholders 3DP requires new skills (installation, operation, control, and maintenance) for workers.

Table 8: Challenges and potentials in applying 3DP. (by authors)

7 CONCLUSION

This study aimed to give insight into applying 3D printing as a new building technology on an international scale and assessing the potentials and challenges in developing and applyingit in countries like Egypt. Based on qualitative data analysis of international examples, the study analysed 3D printing factors, their characteristics, opportunities and limitations. It assessed key factors with theassessment matrix and analysed the applicability of 3DP in the Egyptian Context.

From understanding the role of applied projects and Egypt's economic, social, and scientific situation as a developing nation, Egypt belongs to the second group of countries that import technology and adapt and develop it according to their needs and resources. But there are urgent challenges that need to be dealt with, such as developing local printable materials, updating the regulations and codes, spreading awareness between the different stakeholders and, most importantly, dealing with shifting the job paradigm because 3DP will reduce the need for a significant number of construction workers. While this is considered a benefit for countries with a shortage of labour, it is a disadvantage for countries with a large workforce depending on the construction sector whose jobs are at risk.

Although the technology is still in its infancy, it has continued to gain popularity among researchers and practitioners in the architecture and construction field of some developed and developing countriesworldwide. The future of technology in Egypt is most likely to be a partially built process that allows stakeholders to take advantage of both traditional and 3D printing technologies at the same time. The efficiency of reducing time and waste of materials could be the keys of this technology in the Egyptian context. Moreover, this technology would be applied locally for very limited cases in the near future, such as repairing or reproduction of historical structures, elements designed for interiors, and facade cladding elements. In the medium-term. The construction sector may invest in the mass production potential of 3DPfor affordable housing due to its economic efficiency or invest in flexible design and environmental benefits forfull or partial free forms of luxury buildings.

8 RECOMMENDATIONS

At the level of completing this research, This research provided background and deliberated potentials and challenges of the applicability of 3DP in different cases throughout the world so that future research could match local requirements and properties with the key factors which determine the applicability of 3DP toseveral local contexts. As regardsgeneral 3DP development, further work is needed to explore ways of printing with multiple materials, develop new materials, use in situ resources, faster printing, quality assurance, and mechanical property data, and combine 3DP with other processes such as hybrid techniques to increase the potential of applying it as new building technology.

1 ABSTRACT

Managing the COVID-19 pandemic is a major challenge for decision-makers in crisis staffs, especially on a regional level. Decisions on intervention measures to contain a pandemic must be made promptly and under uncertainty. The project AScore aims at supporting decision-makers by means of an information management cockpit that intertwines smart city technologies and agent-based simulation. This paper introduces the project, outlines the concept and architecture of that cockpit, and presents first use cases and results. It shows what data and analysis functionality is important in pandemic crisis management and how social simulation can inform decision-makers about what intervention measures to put in place for containing a pandemic on a local level–as well as when and how to lift them.

Keywords: Digital Twin, Smart City, Agent-Based Social Simulation, Pandemic Management, Dashboard

2 INTRODUCTION

Managing the COVID-19 pandemic is a major challenge for leaders and decision-makers at different levels of societies. The main reason for this is that the pandemic affects multiple dimensions of human life, that there are numerous conflicting goals, and that responsibilities are often distributed or unclear. Decisions on intervention measures to contain a pandemic must be made promptly and under great uncertainty. In Germany, federal and state governments set the framework for containment of the escalating infection disease following the Pandemic Plans on federal and state level as well as the German Infection Protection Act. However, districts and their health authorities are responsible for implementating specific measures at the local level to meet federal or state decisions. Thus, municipal crisis management at the county level, with implementation regulations, monitoring of compliance with measures and, if necessary, setting additional county-specific measures, plays a crucial role. This pandemic management must balance the often competing demands of (1) avoiding overload of the local healthcare system, (2) fulfilling social, cultural, and economic needs, (3) maintaining availability of critical infrastructures, as well as (4) protecting public health. This task cannot and must not be carried out "blindly". Rather, it is necessary to have access to decision-relevant data, information, and knowledge about the four areas of demand listed above.

During an escalating infectious disease, this data and information situation, as well as its reliability, precision, or uncertainty, changes constantly: If it is initially uncertain and incomplete, "better" data and new knowledge about the respective disease become available with increasing time. In the rarest of cases, this information is available at the municipal level in a way that supports efficient crisis management. This reveals the current information management dilemma in crisis management: While there is an objectively high demand for information, it is met only inadequately with the existing municipal information systems. The main objective of the AScore project presented here is the design and development of a simulation-based management cockpit for municipal crisis management in the event of escalating infectious diseases. Using the example of the municipality of Kaiserslautern and the COVID-19-Pandemic, AScore employs methods from the field of Artificial Intelligence (AI), particularly smart cities technologies and agent-based social simulation.

In the following, we will first introduce the innovative approach to information management by combining available information of smart cities and agent-based social simulation for infectious disease control. The AScore project, information demands as well as the technical architecture, findings of requirements analysis as well as first steps towards a management cockpit will then be presented. Additionally use cases are discussed for demonstrating the utility of our approach and to identify challenges when integrating, analyzing, and visualizing data for decision makers. The paper concludes with a summary and an outlook on future work.

3 COMBINING SMART CITIES TECHNOLOGIES AND AGENT-BASED SOCIAL SIMULATION FOR REGIONAL PANDEMIC MANAGEMENT

At its core, the AScore project presented in this paper builds upon the foundation of combining smart cities technologies with agent-based social simulation. This approach, while being innovative, is not entirely new. In fact, one fruitful combination of those technologies is demonstrated by the well-known CityScope project for urban planning by the MIT Media Lab City Science group (Alonso et al. 2018).[1] In CityScope, city data, analysis tools, and visualization as used in smart cities projects are combined with an agent-based simulation framework as well as participation elements to allow for interactive and dynamic urban planning. The key innovation here is to interleave static analysis and dynamic simulation in order to provide process-oriented insights into possible changes in the city that follow planning decisions.

Without a dynamic component, it is difficult to anticipate the effects of decisions in a changing world. This is also the case for crisis management in the context of COVID-19. Since the outbreak of COVID-19, various information platforms, data repositories and dashboards have been developed.[2] Most of these monitor the disease on an international or national level. Fewer examples cover individual municipalities, and in many cases, these platforms have a particular focus (e.g., monitoring the number of reported COVID cases, reporting the progress of vaccination campaigns, or informing about interventions put in place in order to contain the pandemic). Nonetheless, these platforms utilize a number of techniques that have been developed in the context of smart cities: Spatiotemporal data retrieval and aggregation methods, storage solutions and analysis workflows, as well as visualization and dashboarding frameworks. And some examples even include a dynamic component which uses simulation to forecast possible future developments and compare different counter-pandemic strategies (e.g., Bortz et al. 2020, Dings et al. 2021).

Such forecasts and comparisons are a valuable tool for decision-makers in crisis management. In an ever-changing crisis situation, it is necessary to anticipate what is likely to happen because available data is always delayed and the effects of decisions will only fully unfold at a future point in time. Consequently, decision-makers have to extrapolate on their available information and decide on potential interventions even before these appear to become necessary. Moreover, they have to strike a balance between the expected benefits of interventions on the pandemic situation and the restrictions they impose on the economy, social and cultural live, and the individual freedom of the population. To that end, the aforementioned tools to compare different available intervention measures are valuable assets for supporting crisis managers.

However, the majority of crisis management responsibilities (at least in Germany) are located on a regional and local level. Each municipality has its local crisis management staff, often led by the local mayor and consisting of experts in the affected public fields (e.g., hospital managers, regulatory and health authorities, fire fighters and civil protection agencies, education and other public service authorities). These members of a crisis staff face the challenge to decide about local measures and make their decisions dependent on the respective local situation. They also have their individual perspectives for interpreting that situation and their specific data sources upon which they base their interpretations. For instance, crisis staff and local council members may have to decide which sports facilities can be opened or need to be closed in order to allow for leisure activities while avoidung to expose the population to unnecessary risks of infection. Supporting this type of decision-making requires tools that focus on the pandemic situation in a particular region, that provide detailed analysis functionalities to compare localized intervention measures, and that allow for integrating analyzes from different perspectives and fields of expertise.

To achieve those three goals, the AScore project complements the existing platforms described above with a localized equivalent that is geared towards regional crisis management. This requires collecting and analyzing data about individual municipalities and modelling local intervention measures in detail for simulation purposes. To that end, existing technologies developed at DFKI are newly combined and extended. On the one hand, data sources about the local population, infrastructure, and public services are

[1] See also https://cityscope.media.mit.edu/ and https://www.media.mit.edu/projects/cityscope/overview/

[2] Examples include, but are not limited to the following platforms: WHO Coronavirus (COVID-19) Dashboard (https://covid19.who.int/), COVID-19 Dashboard by CSSE at Johns Hopkins University (https://coronavirus.jhu.edu/map.html), RKI COVID-19-Dashboard (https://experience.arcgis.com/experience/478220a4c454480e823b17327b2bf1d4/), Bundesministerium für Gesundheit Impfdashboard (https://impfdashboard.de)

made accessible to crisis managers. Using smart cities analytics tools, that data is aggregated and visualized to enable assessments of the actual pandemic situation. This analysis takes various perspectives into account in order to provide a more comprehensive view on that situation. For instance, not only numbers of reported infections are considered, but also the impact of intervention measures on the local economy and public life can be visualized. On the other hand, agent-based social simulation is used to model the behavior and daily routines of the local population and to analyze impacts of intervention measures that have not yet been applied. In AScore, the agent-based model utilizes the aforementioned data to build a digital twin of the municipality in focus. Individual persons are being represented in the simulation by agents that act in a typical manner, e.g., according to a person's age. The model also contains a disease component to represent a potential spread of COVID-19 across the population. Additionally, public and private infrastructure is represented in the model such that the utilization of facilities by agents and the impact of intervention measures (e.g., lockdowns) can be simulated. In this way, AScore brings together DFKI's smart cities toolkit with its agent-based simulation technology developed under the term "Social Simulation for Analysis of Infectious Desease Control" (SoSAD).

SoSAD is an agent-based simulation model based on real-world smart city information and data. It has been in development at DFKI and Trier University since early 2020. In this model, all persons of a population are modeled as agents with their respective family relationships and typical daily routines. The daily routines include occupation, school attendance or leisure activities, during which agents can meet. Combined with a disease model (for COVID-19), the spread of an infectious disease can be simulated depending on the activities of the population. This in turn allows for modeling pandemic control measures that restrict certain activities (e.g., closing schools) and thus change rates and possibilities of infectious contacts. By means of systematical simulation, these measures can be compared with respect to their intended effectiveness as well as potential unintended effects. The results can then be analyzed in the same way as real-world data is handled. In AScore, this provides decision-makers with information about hypothetical developments (what-if-analyzes) to complement information about the current actual situation (what-is-analyzes).

Each agent in SoSAD is a digital twin of an individual person of a particular age in years, a demographic information that is retrieved from the AScore data storage. This allows for a detailed representation of cities and municipalities of up to several million inhabitants in the simulation. Depending on their age, the agents are clustered into three distinct behavioral groups with typical daily routines: Children (including adolescents), workers (including students), and pensioners (i.e., all agents above the age of retirement). Similar to other agent-based modeling approaches (e.g., Huang et al. 2005, Bicher et al. 2020), agents of each group frequent a number of particular locations where they can meet other agents. Workers have a workplace which can represent a private company, a public service agency, as well as a university or other higher education facility. Children instead go to school. Agents of any age have a home where they either live alone or together with other agents. Furthermore, all agents frequent leisure facilities which represent shops as suppliers of essential and non-essential goods as well as cinemas, gyms, stadiums and concert halls as well as any other public place for recreational activities. Real-world information about any of these locations is retrieved from the data storage to generate a digital twin of a particular city's infrastructure for the purpose of social simulation.

Two agents that frequent the same location can meet each other there. Since not every encounter will be potentially contagious, SoSAD only models those contacts that are sufficiently intense to spread the virus. In these instances, contagion takes place with a certain probability if one of the agents carries the virus and is infectious. This is the same basic principle as in most other agent-based COVID-19 contagion models (Lorig et al. 2021). The model of disease states and their progression is analogous to a modified SEIR approach as published by the Robert Koch Institute (RKI), the German government's central scientific institution for biomedicine and public health (an der Heiden & Buchholz 2020).

Any agent that has not yet been vaccinated or infected with the virus is susceptible to it (state S). If the virus is transmitted to such an agent, that agent becomes exposed (E). After a latency period, the agent becomes infectious for a period of time (I) during which it can infect other agents. In the case of COVID-19, an agent becomes infectious before it may develop symptoms of illness. There are six levels of symptoms, one of which is predefined for each agent according to a distribution as observed in sample studies of COVID-19 cases (e.g., Dong et al. 2020, Zhou et al 2020): asymptomatic, minor, moderate, severe, critical, and fatal. Depending on its symptom level, an agent will be unable to even recognize its infection without test, it may or may not stay at home, become hospitalized, require intensive care and eventually either recover or pass away. If agents stay at home or become hospitalized, they will no longer have contacts at work, school, leisure facilities, or at home. Recovered agents will become immune to further infection (R). The same holds for agents that have received vaccination. These become immune with a specific probability that depends on the vaccine's effectiveness.

In addition to vaccination, SoSAD implements several pharmaceutical and non-pharmaceutical interventions to control the simulated pandemic. These can either reduce the infection probability in case of a contact between agents (e.g., by wearing face masks or using air filtration) or the ability for an agent to even meet others (e.g., through contact restrictions and lockdowns). Agents become aware of activated interventions, and they can decide whether to follow the rules or whether to violate them. For instance, if leisure facilities have been closed, agents can still meet in private, and they decide for themselves if they wear protective masks on such an occasion or not. This allows for analyzes of interventions in the presence of non-conformant behavior. In AScore, a library of counter-pandemic measures is provided. Any combination of interventions forms a simulation scenario that can be compared with alternative scenarios in order to gain insights into possible regional strategies for containing the disease. Because implementing these measures can have impacts on, e.g., both the spread of the disease and the local economy (in case of a localized lockdown), such a comparison enables crisis managers to make informed decisions considering multiple perspectives on the situation. Making that functionality accessible to crisis managers is the main goal and the most important innovation of AScore.

4 THE ASCORE PROJECT

4.1 Project Context and Partners

AScore[3] is a consortium project funded from 01/2021 until 12/2021 within the framework of the special programme "Zivile Sicherheit – Forschungsansätze zur Aufarbeitung der Corona-Pandemie" by the German Federal Ministry of Education and Research (BMBF) under grant number 13N15663. AScore brings together partners from AI and smart cities research (DFKI GmbH), mathematical optimization and epidemiological simulation (Fraunhofer ITWM), data science for business (CID GmbH), as well as crisis management (VfS e.V. and mata:solutions GmbH). To realise pilot scenarios, the City Administration of Kaiserslautern joined the project as an associated partner. Transferability of the results is ensured by the City Administration of Trier being a second application partner.

4.2 General Vision of AScore

AScore aims at improving the crisis management such that decision-relevant information is available for assessing potential intervention measures to contain a pandemic. To this end, a cockpit is being designed and implemented, which covers the areas (1) avoiding overload of the local healthcare system, (2) fulfilling social, cultural, and economic needs, (3) maintaining availability of critical infrastructures, as well as (4) protecting public health. For these areas, real world data is collected, analyzed, and aggregated in a pandemic pressure scoring system to visualize and assess the current situation. The same process is also used for integrating synthetic data from simulations of what-if-scenarios, which compare possible effects of different intervention measures. The agent-based social simulation system SoSAD, developed at DFKI and adapted to the Kaiserslautern region, allows for implementing such measures on a detailed level and observing their effects on the interactions and, thus, infection dynamics within a realistically simulated population.

5 ASCORE APPROACH AND ARCHITECTURE

5.1 Information demands

Data in AScore is used for three main purposes:

(a) to provide information about the current status,

(b) as input for and output of the SoSAD Social Simulation, and

(c) as part of the measures-impact repository.

---

[3] See https://ascore.kl.dfki.de for more project information.

We will now discuss each of these purposes as well as the data involved in more detail.

5.1.1 Status Information

For all areas to be covered in the management cockpit, information about the status including important news or developments is required. This includes information about the citizens actually infected, capacities in the local health system, availability of critical infrastructure as well as information about impacts on social, cultural, and economic aspects. For all these areas, data sources need to be identified in close exchange with relevant stakeholders from the fields as well as from crisis management. In order to be able to make use of the data sources, a variety of tasks have to be solved. These range from technical accessibility to clarification of data protection aspects.

5.1.2 The SoSAD Social Simulation

The social simulation component takes data as input and produces additional data as output. From the input data, it parameterizes the agent-based model by means of model generators. These generators pre-process and aggregate data from several sources before it can be used in the model.

The most important generator populates the simulation with agents. It uses actual or synthetic demographic data to construct an agent population. In the case of actual data, a municipality’s register of residents is directly fed into the population generator. From this data, an agent with a corresponding age is created for each resident. If several persons live together, their respective agents become connected in the same household. These households are grouped by statistical districts to abstract from addresses and make individual persons harder (or impossible) to identify. To guarantee anonymity, registry data can also be replaced with a synthetic population generated from census data. In either case, the population generator uses as little data as possible to construct an accurate digital twin representation of a municipality’s inhabitants for social simulation.

Furthermore, there are several generators for a municipality’s infrastructure that agents in the simulation can frequent. For instance, children attend schools which are generated from data about the numbers of pupils and classes per grade for each school. This is combined with the population data to assign agents with an appropriate age to school classes. From these assignments, a generator creates schools and classes as locations in the simulation model and populates these with the respective agents.

In order to run the simulation, AScore also stores and provides a library of scenarios. In these, combinations of counter-pandemic intervention measures are specified which can be compared using simulation. The SoSAD component takes the chosen scenarios from the management cockpit, creates the respective parameterized simulation model using its generators and then runs the simulation to produce the required results. Those results are also defined by the scenarios in terms of output variables that will be compared. Thus, simulations in AScore can essentially be run in the form of hypothesis-driven studies that provide comparative answers to questions about the impacts of intervention measures (Lorig et al. 2017).

The results of those simulation studies are finally returned to the data storage. They can come in the same form as real-world observations about the actual situation. This enables the analytics engine and the management cockpit to utilize the same tools and visualizations for comparing hypothetical what-if scenarios as for displaying the current what-is situation. The goal of this approach is to make simulation as an advanced decision-support technique accessible to non-specialists in crisis management.

5.1.3 The Measures-Impact Repository

One of the goals in AScore is to establish structures that allow for analyzing the quality of intervention measures taken during a pandemic. In order to do so, a Measures-Impact Repository is being developed in the project. That repository is meant to store information about which measures had been taken in the past and what effects could be observed with respect to the various dimensions of the Pandemic Pressure Score. This is a complex task, since it is almost impossible to identify, capture, and store all information that constitute the current status in all its complexity, let alone the factors that have an influence on the state and are not simply defined in an official, pandemic-related measure. E.g., factors like weather, mobility or the influence of media can often have a massive impact on the development of a pandemic disease.

Yet, even without the complete picture relevant information can be gathered. On the one hand, this includes all information about the official measures to contain COVID 19. They need to be translated to a common representation allowing for a comparison between different measures (see Section 5.3.2). On the other hand, it contains at least all status information (see Section 5.1.1) provided through the Management Cockpit.

Since data are often corrected over time (e.g., due to delayed reporting of cases of illness), it is misleading to use the corrected figures retrospectively. If one wants to reconstruct which information was available on a certain day within a management cockpit to support decision-making, a much more complex procedure is necessary to enable such reconstructions–also with regard to the resources available for data storage. Consequently, histories of data series are captured in AScore in the exact form that they had at the time of decision about intervention measures, e.g., for the figures on incidences and deaths collected by RKI.

Moreover, the Measures-Impact Repository connects data from different sources to allow for a more complete picture. For instance, the measures themselves can be extracted from official regulations and decrees as publishes by municipalities and states. These are then linked to directories of registered businesses in order to establish how many companies in which business areas or trades are affected by these measures (e.g., in a partial lockdown). Similar connections include directories of schools, sports facilities and other locations with registers of residents to analyze impacts of measures on families, requirements for emergency childcare, as well as physical and mental well-being. Linking data in this way allows for capturing the particular impacts of intervention measures not only on viral spread but also on public and private life in general.

5.2 AScore Infrastructure and Components

One of the aims of AScore is to provide a prototypical infrastructure that illustrates the potentials of the approach and that allows for being used as a basis for further developments by project partners and other stakeholders. In order to realize this, it is possible to build upon several existing DFKI components (cf. Memmel et al. 2017, Sabty et. al 2013) that are being enhanced and adapted for the needs of AScore. This, e.g., concerns data integration, data storage, and interfaces for data provision, simulation model components and generators, as well as components for data visualization. Yet, some tasks require a considerable amount of refactoring or even the development of completely new components. Fig. 1 provides a coarse overview of the AScore infrastructure and main components that will now shortly be introduced.

5.2.1 Adapters & Preprocessing

In AScore, both (quasi)-static and dynamic data are processed. Quasi-static data sets (e.g., municipal registration data, POIs, or data from OSM) change only after comparatively long time intervals and therefore need to be updated less often than dynamic data. The latter are transmitted via service interfaces. In any case, appropriate adapters and connectors for (semi)automatic integration and normalization of both quasi-static and dynamic need to be available.

Furthermore, different preprocessing steps are required that allow for an appropriate access to data (e.g., for the AI analytics Engine and for interactive visualizations), an efficient storage, or the integration into the measures-impact repository.

5.2.2 Data Storage

The data repository is a central component in AScore, combining elements of classic spatial data infrastructures with other modules, e.g., that allow for an efficient storage and management of textual data. The data storage will contain all input data relevant for the tasks described in Section 5.1.1, 5.1.2, and 5.1.3. The data storage will also provide refined data and intermediate results, as well as the metadata, especially also with suitable historization concepts to be able to observe temporal changes.

5.2.3 AScore API

In order to allow accessing the data in the data storage, the communication between different components, and especially the access for the AScore Management Cockpit and 3rd party applications from other stakeholders and project partners[4], an API will be developed.

[4] In the project, two sample applications are covered here: EpideMSE by Fraunhofer ITWM and the Coronavirus Exposure Tracker by CID GmbH.

5.2.4 AScore Analytics Engine

This component holds all methods to analyze data within AScore. This includes aspects such as the calculation of a Pandemic Pressure Score and algorithms to find patterns in the measures-impact repository. The engine makes use of various methods, described, e.g., in (Wang et. al 2018) and (Janowicz et. al. 2020).

5.2.5 SoSAD social simulation

This component encapsulates the agent-based social simulation as described above. The simulation interacts with the AScore API using its input and output data generators. Real-world data is retrieved from, and simulation results are stored in the Data Storage to make the simulation accessible to the AScore Management Cockpit as well as any 3rd party applications. Moreover, this makes simulation data also available to the AScore Analytics Engine for comparing scenarios according to their Pandemic Pressure Scores and further analyzes.

5.2.6 AScore Management Cockpit

The Management Cockpit denotes the visual user interface for crisis managers. It comprises a dashboard for what-is-analyzes to increase awareness of the current pandemic situation as well as scenarios of available intervention measures to compare what-if-analyzes for decision-support. Since there are different perspectives from different fields of expertise present in a crisis management staff, the dashboard and the analyzes can be customized to individual information needs. However, being based on the same Data Storage and analysis tools, the AScore Management Cockpit furthers communication and agreement between staff members.

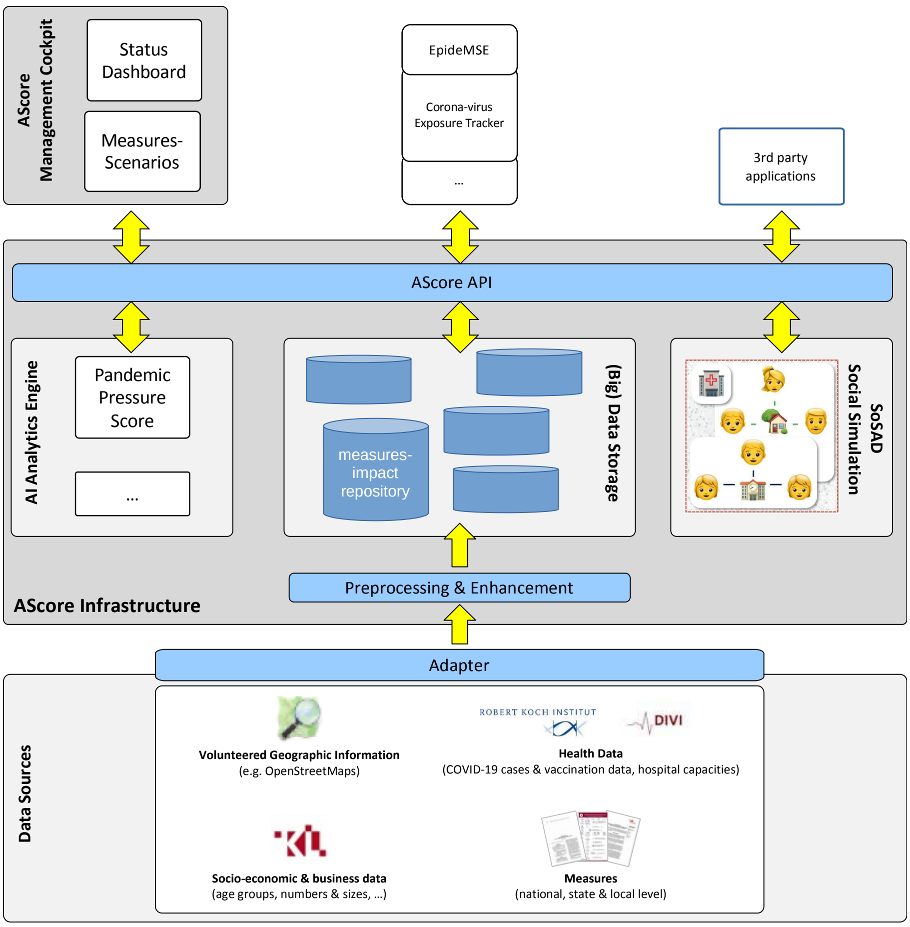

Fig. 1: A coarse overview of the AScore infrastructure and main components.

5.3 Realizing a Management Cockpit – First steps

As a basis for discussing requirements and needs with stakeholders from crisis management and also within the AScore project team, first steps to realize the envisioned management cockpit were already realized. Figure 2 provides an overview of some of the available information as of May, 2021.

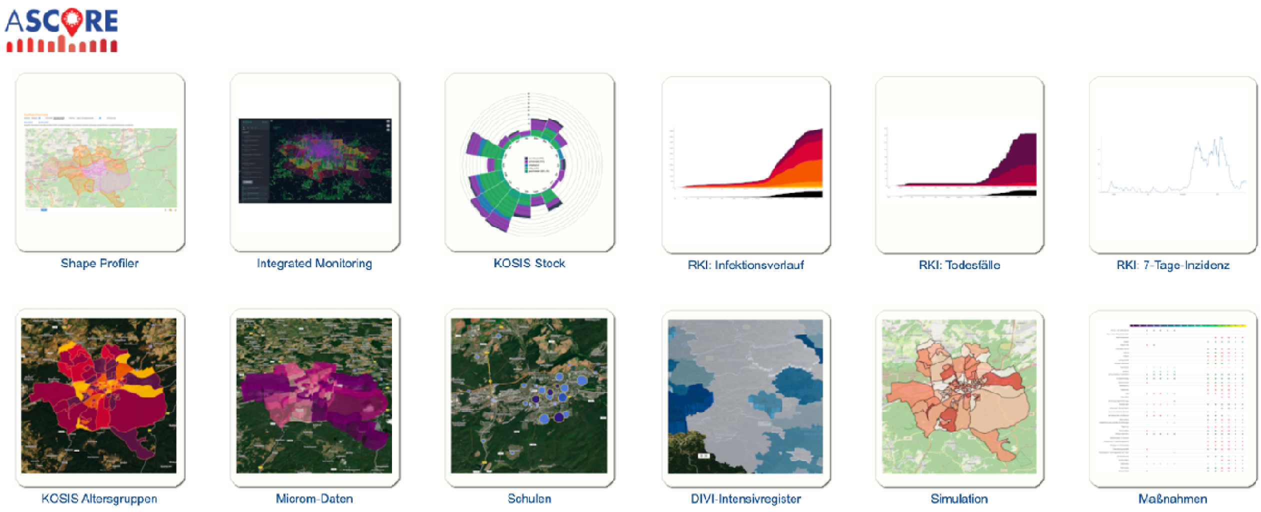

Fig. 2: Overview of information items available in the early development stage of the AScore management cockpit.

5.3.1 Map-based Status Information

Map-based visualisations are often particularly suitable for enabling assessments of different statuses or developments at the regional level or in comparison to other regions. In the context considered here, this applies to many forms of information, some of which are shown in Fig. 3:

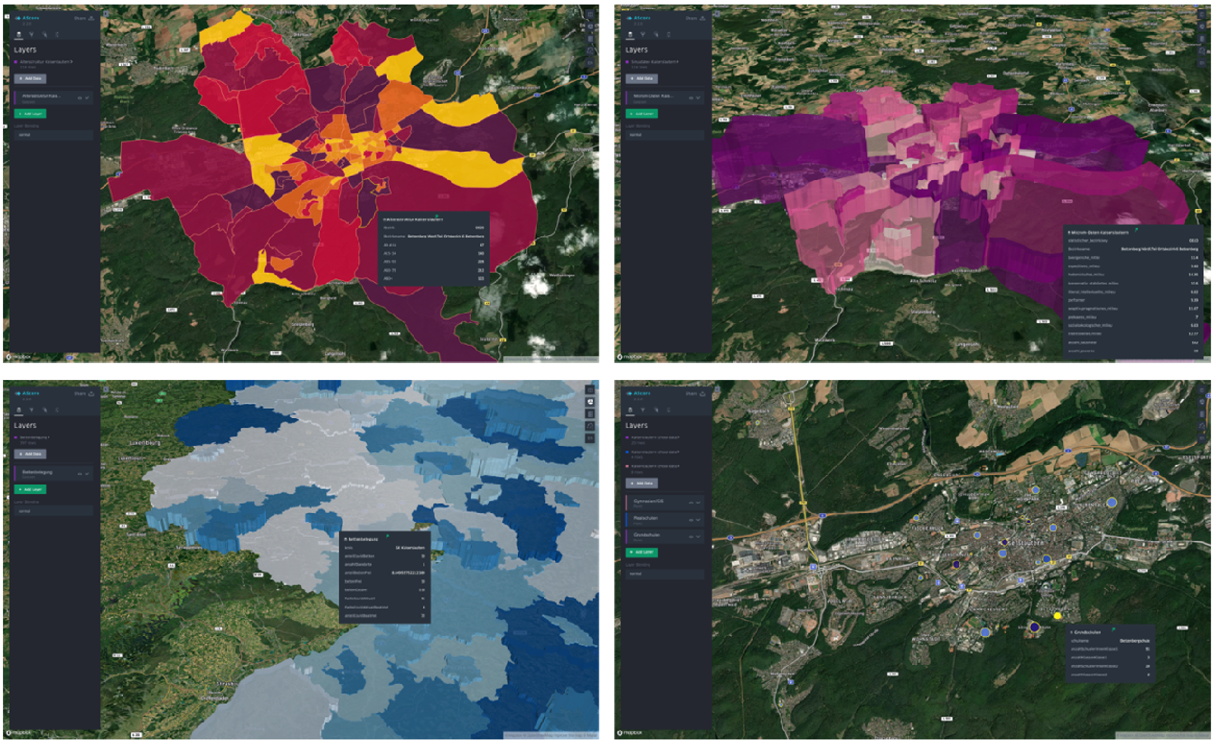

Fig. 3: Interactive, map-based visualization[5] of (a) age groups, (b) business activities, (c) ICU capacities, and (d) schools (clockwise).

(a) The distribution of age groups (and social milieus) can be used, for example, for specifically addressing certain population groups or to put a focus on social groups that may be particularly vulnerable. The age groups shown here are derived from civil registration data that the city of Kaiserslautern provided in a standardized format (KOSIS).

(b) Information on various business activities (in this case provided in microm data about Kaiserslautern) allows to draw conclusions, for example, about the effects of pandemic containment measures.

[5] AScore builds upon an integrated monitoring infrastructure developed within DFKI's SmartCity Living Lab. It is a generic, module-based web application built upon a distributed data storage and offers several means for visualizations. The interactive visualizations shown in Fig. 3 were realized using the open-source software kepler.gl.

(c) Register information about the availablity of hospital capacities allows to estimate the development of the severeness of the pandemic and to react as soon as posible if capacities become scarce. The information depicted here derives from the DIVI Intensive Care Register, a real-time data collection and analysis environment for intensive care bed capacities and aggregated case numbers for Germany.

(d) The representation of schools with information on the age groups taught there allows, for example, adequate mobility planning.

5.3.2 Visualization of Intervention Measures

In the course of the pandemic, various authorities (federal, state, municipal) adopted a wide range of measures to contain COVID 19. These affect a wide range of social aspects in a variety of ways. For example, different rules apply to large events than to trade or schools. In many cases, the rules within individual sectors are also very differentiated and often apply depending on local incidence figures. In order to enable an overview of measures that are currently valid and those that were valid in the past, an interactive visualisation of such measures was developed in AScore (see Fig. 4). On the y-axis, different areas affected by intervention measures are displayed, on the x-axis the measures (grouped by regulation or as a timeline) are shown. The colors indicate how much the respective areas have been affected by the measure: "red" indicates that they have to be completely closed, "yellow" means a medium impact, and "green" indicates that the area was not affected. This tool requires a comparable representation of areas across different measures and has been realized, among other things, based on publicly available readout aids.

Fig. 4: Interactive visualization of pandemic containment measures and affected fields of society in two different modes of presentation: and grouped by regulation (left) and as a timeline (right).

6 SAMPLE USE CASES: SITUATION EVALUATION AND DECISION SUPPORT

Over the course of a pandemic, crisis staffs meet regularly to evaluate the overall situation and to decide whether action needs to be taken. Consequently, use cases of the AScore project can be grouped into two main areas: Those that cover general information interests and those that directly support specific decisions. From general information, crisis staffs can derive the need for action whereas decision support only comes into play as a second step when deciding between several alternatives.

For evaluating the current pandemic situation, crisis staffs require an overview in the form of situation reports. These need to be up-to-date and cover the various areas of expertise of different staff members. To meet these demands, users can customize their view of the Management Cockpit with those detailed analysis components they deem important while still keeping an overview of other areas through the Pandemic Pressure Score. For instance, the local health authority has to report on registered infections and work together with hospital managers to reserve capacity for expected severe cases that will need intensive care. Having a localized and customized dashboard available helps these users communicate with each other. In particular, they can observe the current situation as well as similar ones from the past (if available) to make sure to call for action at the appropriate time. The Pressure Score is their main asset for doing so: If the public health situation deteriorates, pressure on the healthcare system will increase. The AScore management cockpit uses that score to help detect these developments and interplays through indicators, what-is-analyzes and visualization such that intervention measures can be taken in a timely manner.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

However, the Pressure Score does not only help determining when to intervene to contain the pandemic. Since intervention measures exert pressure on private and public life, culture and economy themselves, the score is equally important to detect potential and find ways for alleviating that pressure. This leads to specific decision-making tasks for a crisis management staff. Both putting measures in place as well as lifting them requires decisions about which specific interventions are appropriate and how they can be designed to have the desired impact while avoiding undesired side-effects. To that end, decision-makers use what-if-analyzes to compare hypothetical scenarios of situations that have not yet been observed in reality.

In this role, an early version of AScore has already been utilized for supporting decisions by crisis staff members and municipal councils. Examples cover decisions about when and whether to open or close schools (and how to organize public transport accordingly) as well as whether to open public swimming pools. In that context, simulation scenarios were run in which schools were closed completely, opened as normal, or opened for only half the students at a time with regular rotation of the cohorts. These scenarios were analyzed not only according to the number of expected infections in school but also according to the possible further spread of the disease (i.e., with respect to the role of schools as a multiplier of the general infection dynamics). It turned out that the rotational strategy increases infections across the population only slightly over completely closed schools–while at the same time drastically decreasing the organizational burden upon families. These results were visualized by means of time series plots, scenario heat maps, and geographical analyzes of locations for potential outbreaks of COVID-19. Up to the time of writing, the rotational strategy has been in place for several months and no major outbreaks have been reported in the partner cities that derive from infections in school.

7 SUMMARY AND FUTURE WORK

To summarize, the AScore project aims at developing an information system for crisis managers in the context of pandemics. Its core contribution and innovation is in bringing together smart cities technology for data retrieval, analysis, and visualization with agent-based social simulation. While the former supports what-is-analyzes of the current pandemic situation to identify the need for action, the latter allows for comparing what-if-analyzes of hypothetical scenarios to decide upon which specific action to take. This paper has outlined the overall concept of AScore, introduced its architecture and components, and briefly sketched its uses for practical decision-making. AScore, however, is still being developed and there is still work to do. This implies several challenges that need to be overcome. Firstly, additional indicators for the Pandemic Pressure Score must be specified and implemented. This is challenging because data private life and public institutions is hard to retrieve due to privacy or security reasons. Secondly, presenting analysis and simulation results to crisis staff members in a meaningful way is a non-trivial task. Future work will thus cover customizability of the dashboard and scenario components. Finally, AScore is meant to provide open interfaces for 3rd party analysis tools. These will be developed and tested with sample tools of the project partners.

Beyond the AScore project, the combination of agent-based social simulation and smart city technologies is being further developed for many other urban application areas, such as urban planning or climate protection.

1 ABSTRACT

Globally, spatial planning and development systems have proven to be critical instruments for establishing long-term, sustainable frameworks for improving social, territorial, and economic development conditions. In developing cities, spatial planning and development systems are generally used to enhance the integration between sectors such as housing, spatial justice, transport, energy and industry, and improve people's quality of life. This paper uses a case study research approach to unpack how spatial planning and development systems have contributed to the enhancement of society’s living conditions in the City of Johannesburg, South Africa. Interviews with key stakeholders and questionnaires were used to gather information from the University of Johannesburg, the City of Johannesburg Municipality, and the Housing development Agency. The findings reveal a need to develop institutional and financial mechanisms to improve communities' quality of life and planning tools designed as drivers for spatial change. The paper also highlights the challenges that hinder appropriate living conditions and urban transformation, including high urbanisation rates, poor service delivery, high rentals, and unemployment. The paper concludes with a discussion of the significant gaps in knowledge that concerns the implementation of spatial planning and development systems in urban areas for the purposes of improving the status quo. The work recommends the adoption and implementation of adaptable and regenerative spatial planning as a vehicle for the improvement of living conditions in cities of the developing world.

Keywords: Spatial, sustainable frameworks, urban transformation, quality of life, Johannesburg

2 INTRODUCTION

The spatial injustices of apartheid and rapid urbanisation had a large influence on the spatial structure of Johannesburg, with negative development shortbacks such as urban sprawl, spatial inequalities, fragmentation, limited mixed-use development and people-oriented spatial planning development. Despite, the evidence of spatial rectifications and reconstructive developments that has been introduced in the previous years, the current spatial planning and development systems require extensive reviews in order to match the status-quo of the community needs in the city as well as meeting the future spatial visions. Spatial injustices in the city of Johannesburg remains a definitive element of the quality of life, settlement patterns and urban sprawl. The lack of spatial integration has led to misalignment in locations and concerntration of economic opportunities. The housing-job approach does not match and create inequalities in the city, concerntration of socio-economic activities does not correlate to the location where people live (Bertoldi, 2015).

The present spatial planning and development system introduced known as, Joburg Growth and Development Strategy 2040 is a key priority spatial planning and development strategy that directs spatial growth, defines the type society and development the city intend to achieve by the year 2040. This strategy capacitate the city with institutional powers to resolve the unattended past development and spatial injustices which emerged from apartheid regime meanwhile moving towards a just city, non-prejudiced and developmental city (Harrison & Todes, 2014). Nevertheless, traditional approaches have been adopted in many developing countries to foster effective relationship between the spatial planning, development systems and society, particularly these approaches were imported from North America and Europe. Unfortunately, the adoption of these approaches in developing states led to more isolated land uses, activities, society while they were serving the interests of colonial communities. For instance, sub-Saharan

African communities attempted to improve the standards of living through the nationalisation of resources and all land, while some countries such as Zimbabwe and Delhi have shown limited success in the allocation of such lands for development purposes (Ebrahim, 2017). Across the world, cities are faced with complex spatial planning and development challenges. These challenges threatens the future of cities as they tend to become more uncertain and unpredictable, the spatial development planning paradigm of cities has been altered with anthropogenic drivers. In this regards, city spatial planning strategies must direct the tension between future spatial uncertainities, development growth paths and adequality quality of life.

According to Schensul & Heller (2010), cities in South Africa particularly the city of Johannnesburg, Ekurhuleni, Pretoria and Durban are demonstrating a clear example of spatial inequalities and development fragmentation. The post-1994 spatial planning legislation and development guides were meant to transform social exclusion, injustices and disparities from the apartheid regime- their preliminary objective was to improve the quality of life of society who became victims of land dispossession and spatial injustice using various interventions such as integrated public transport, reconstruction development plan, housing delivery, adequate health, social services, corridor and nodal development. As a result of these interventions, many lives have been transformed through land reforms, delivery of more than four million housing backlogs and development of integrated and inclusive city (The Presidency, 2014). The adequate spatial planning and development system has the potential to influence the urban growth and livelihoods of Johannesburg by addressing major spatial discontinuities and providing sustainable frameoworks that will present significant areas of economic opportunities. This paper assess the efficacy of spatial planning and development systems in improving the living conditions of the society in the city of Johannesburg. The study will specifically focus on the challenges that hinder appropriate living conditions and urban transformation, including high urbanisation rates, poor service delivery, high rentals, and unemployment.

3 LITERATURE REVIEW

Spatial planning and development system can be seen as a transformation of the city fabric that is spatially defined and builds on multifaceted series of resource driven practises, in which the land use form, substance and development implementation of urban space are intentionally altered to show the principles of spatial refrom and equitable social order (Williams, 2000:169). The concept of spatial planning and development systems has gained popularity as tools to redress the past spatial injustices and restructuring of new urban change. However, these space transformation tools can be related to the drivers of living experiences for urban dwellers. Essentially, a more productive, inclusive, well-planned and sustainable city is characterised by residents benefits of high quality of living and close proximity to functional spaces, these elements contribute towards place-making and shaping the city (Max-Neef, 1992). This section provides critical review of contributions made by other scholars in as far as spatial planning and development systems are concerned in terms of legislative and policy frameworks, stakeholder roles, strategies and global experiences.

3.1 Unpacking Spatial Planning and Development concepts

Spatial planning is a prominent function of a public sector to drive the distribution of future spatial activities. This planning tool is responsible to allow more informed territorial allocation of land uses and integration amongst them, to balance the needs for development with the aim of protecting the environment, attain social and economic objectives. Spatial planning intends to improve and manage the effects of various sectorial legislations and policies on land use development, to achieve a more equal share of economic opportunities within regions. Therefore, spatial planning is a critical lever for achieving sustainable development and improving the standards of living of the society. The techniques provided by spatial planning assist the local government to equally distribute the natural resources, communities and spatial activities of different scales to improve the built environment, social and economic sectors of the society.

Spatial planning cut across mutliple disciplines such as land use development, transportation, urban regeneration, regional and community planning. On the other hand, development is closely related with spatial planning. Development is refer to as the process of creating growth, positive transformation and progress with regards to the addition of economic, social, environmental and physical transformation (Todes, 2015). The role of development is to ensure that the spatial planning objectives such as infrastructural development, mixed use development, economic growth etc are measurable and implemented onto practises with relevant policy-guide and developments guide. Development shapes the urban fabric in terms of organising land-uses, responsible growth of urban spaces, enabling accessibility through various transportation modes, enhance adequate human settlements which are resilient to natural disasters and conducive to human quality of life.

3.2 Legislative and Policy frameworks in Spatial planning and Development

European Spatial Development Perspective (1999) was introduced as a policy document to transform the european cities towards a more equitable and sustainable territories of the European union. The objective of this policy is to drive the development towards the three fundamental goals of European policy and ensure are attained equally around the regions of the European Union, which are preservation and effective management of natural resources and cultural heritage; social and economic cohesion; a balanced competitiveness in the territory of the Europe. In essence, the European Spatial Development Perspective is applicable to Johannesburg as it wishes to conduct a balanced and sustainable spatial development policy which is complementary to the spatial planning goals that are outlined in the City of Johannesburg Spatial Development Framework. However, the basic skeleton of this perspective is narrowed down to its exclusion of urbanization as a driver of spatial planning and development which is a true reality in the city of Johannesburg.

Land Use and Spatial Planning Act 925 of 2016 (Ghana), provides for uniform spatial development and land use planning across national, regional and district level in Ghana. This framework established Spatial Development Planning Fund and Spatial Planning Authority that are mandated with functions of providing sustainable development of land and human settlements using a decentralised planning and development systems. This act revise and integrate various legislation on spatial planning and development in order to improve quality of life of the society, enhance economic growth and promote safety and health in human settlements. The LUSP Act prioritize issues of spatial fragmentation, inequality and mixed use development which are preliminary ills of the Joburg spatial planning, despite the efforts for spatial redress this policy draws its setback on exclusion of the marginalised groups in the production and distribution of space.

Spatial Planning and Land Use Management Act 16 of 2013, this act serve as the national law of spatial planning and development in South Africa that was promulgated in 2013. It is mandated to provide a uniform framework for land use managenment and spatial planning in the country, unlock inclusive, developmental and efficient spatial planning across different spheres of government. Amongst one of the key objectives of this law is to address the past spatial and regulatory imbalances that emerged from apartheid government and ensure that there is equitable development across the country. SPLUMA policy becomes relevant to this study as it emphasises redress, social justice, community participation and capacitate public institutions with powers to shape and influence city growth and development. However, the drawbacks of this policy are limited justifications on current pressing issues such as climate change, industry 4.0 and smart city development.

3.3 Strategies in the provision of Spatial Planning and Development

The Municipal Systems Act 32 of 2000 makes a provision for local municipalities in South Africa to produce an Integrated Development Plan, that outlines the future of the cities over the short, medium and long-term period. The Integrated Development Plan consider issues such as spatial planning, economic development, risk management and performance measurement systems. This super plan directs the overall framework of development and attention to a coherent strategies that improve the quality of life for all the society within the jurisdiction of the municipality and look at socio-economic development of an area as a whole including service delivery and infrastructural development. As part of the IDP, there is a component of Spatial Development Framework which makes provisions for future spatial planning and development desirability of cities as well as issuing a directive for coordinated and uniform development.

3.4 Challenges in areas of Spatial Planning and Development

This section outline an overview of key areas that impose various challenges for spatial planning and development, focusing in the City of Johannesburg. These challenges include demographic change, globalization, spatial inequalities and job-housing mismatch, exclusion and increasing informalities.

- Demographic change

The city of Johannesburg metro area is currently having a population of 5 927 000 in 2021 with aa 2.50% increase from 2020. Tracing a year ago in 2020 the city had a population of 5 783 000, with an increase of 2.63% from 2019 (City of Johannesburg IDP, 2020). These demographic trends are a cause for concern to areas of spatial planning and development with regards to coordinated land uses, service delivery and economic development. The growing population in the city give rises to activities such as land invasions, informal erection of dwellings, highjacking buildings, increase criminal activities and pressure on available resources and infrastructure.

- Globalization

The trends of globalization has positive and negative implications for the city of Johannesburg which include the growth of competitive economic markets, limits to the state intervention in developments, the demise to traditional life in the city, economic pressure as the city is benchmarked with international cities, the demand to develop as a world class city which has implications on the environmental sustainability and loss of unique identity of the city.

- Spatial inequalities and job-housing mismatches

In Johannesburg, there are still evidence of spatial inequalities and development fragmentation. The urban poor are still situated in places that are far away from economic opportunities as well as jobs. The large region D of the city which is made of South-Western township (SOWETO) is still undergoing issues of power cuts, lack of connectivity, integrated transport systems and adequate service delivery (City of Johannesburg, 2011). Meanwhile, areas in regions such as Sandton in Region E is kept under constant development and adequate services.

3.5 Stakeholder roles in Spatial planning and Development

Successful implementation of spatial planning strategies and develeopment is largely dependent on the institutional support of all stakeholders including the civil society, non-governmental organizations and public-private sector. Involvement of various stakeholders provides a shared-knowledge, information and skills/support that improves informed decision-making in the processes of spatial planning and implementation of development. The engagement of stakeholder also enhance understanding as well as increased support for proposed policies and strategies. For example, the provincial government of Gauteng in South Africa introduced and implemented the project of e-tolls in freeways of cities including Johannesburg; the systems were developed to fund the R20.1 billion highway upgrade program in 2007-2011, however, due to lack of effective public participation the project is not generating enough revenue as anticipated because of backlash and limited support from the society (National Planning Commission, 2011).

3.6 Review of Experiences (Developed, Transitional and Developing countries)

European spatial planning and development systems are informed by the a document drafted in 1999 called European Spatial Development Perspective (ESDP), which has influenced the spatial planning and development policies in the European Union member states. The European Union emphasised an integrated approach to spatial development planning, and The Urban Agenda calls for an equitable, sustainable and unified approach towards urban challenges, taking into account the Leipzig Charter on sustainable European cities that focuses on major elements of urban development (including social, economic, environmental, cultural and territorial aspects) (European Union, 2008). Furthemore, The Urban Agenda of the EU advocate for a direct relationship with the New Urban Agenda of the UN as well as sustainable development goals to unlock potentials of sustainable urban land use and focus on issues of affordable quality housing, eliminating poverty, limit urban sprawl and social inclusion (Faludi, 2003:09).

In the Federation of Russia, there are various types of spatial planning and development systems adopted by the state: strategic, spatial, socioeconomic and financial. These approaches in all forms of planning are administered by the normative legal acts and legistlave frameworks. Across the spheres of government there are Land use planning schemes of the state Federation that regulate and monitor fields such as federal transport, urban sprawl, quality of life and service delivery (Petrov, 2011).

In the case of Uganda, spatial planning and urban land use are facilitated under the Town and Country Planning Act Chapter 246 of 2000 and the Physical Planning Act of 2010. The urban growth in Uganda is described as unplanned, with high levels of urban sprawl, lack of uniformity between sectoral and spatial planning, poor provision of basic services, significant financial constraints and weak urban management capabilities (Somik Lall, 2012:17). The spatial planning and land use development system in Uganda are closely linked with corruption and political power. As a result, unplanned and chaotic development is prevailing the cities and making it difficult for spatial planners to develop towards urban sustainability and adequate living environments. Over 60.1% of the urban population is found in slum dwellings of poor infrastructure such as poor road network, drainage, sanitation, solid waste and unplanned neighbourhoods that are vulnerable to natural hazards.

3.7 Theoretical Framework

Lefebvre's theory of production of space models the analysis of this study. As a Marxist thinker, Lefebvre (1991) elaborate on the production of space through a three-part system betwen everyday practises and perceptions, representations and the spatial imaginary of time. The primary argument is that the space is a result of a social product which is based on the value and social production of meanings that moulds the social practises and perceptions (Lefebvre, 2014). Therefore, it is reasonable to use this theory as a guide to assess the efficacy of spatial planning and development system in improving the quality of life in the city of Johannesburg because the foundation of this theory assume that that spatial practise, development of space and representations of spaces contribute in various ways to the qualities of the society and as well production of space.

4 STUDY AREA

The city of Johannesburg is classified as the economic powerhouse of Gauteng, South Africa and Southern Africa at large. It was founded in the late 1880s during the discovery of the gold Reef on the Witwatersrand. The metropolitan of Johannesburg emerged in 2000 by the merger of five interdependent municipal areas which covered a total area of 1 644 km2 with a density of 1 963 persons per square kilometre (City of Johannesburg IDP, 2020). Johannesburg is surrounded by the two independent metropolitan areas of Gauteng, namely: City of Tshwane and Ekurhuleni. The city is made up of a 5,92 million population currently spread across 1 434 856 households with an average of household size of 2.8 persons per household (StatsSA, 2013).

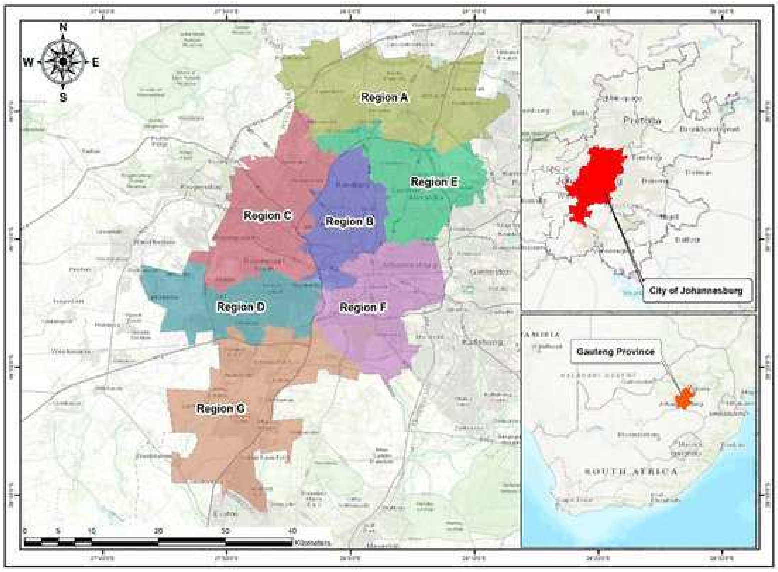

Figure 4.1: Study Area of the City of Johannesburg. Source: City of Johannesburg (2015)

The development in the city is priotised within and spiralling outward from the urban centre with high densities of residents, amenities and economic activities. At the heart of the vision compact polycentric Johannesburg consist of a strong metropolitan core and the inner city. This core embodies the urban qualities that details the spatial transformation themes of building a compact, connected, inclusive and resilient city.

5 APPROACH AND METHODOLOGY

This research adopted a case study phenomelogical design to generate in-depth, multi-dimensional and critical understanding of spatial planning and development system in the city of Johannesburg. The case

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

study design allows for the exploration and understanding of complex issues, it can also be regarded as a robust research method especially when a holistic, in-depth and multifaceted investigation is required (Johnsons, 2006). Through case study method, this research went beyond the quantitative statistical results and analysed the behavioural conditions through the actor's perspective. It was noteworthy to note that despite problems in the city such as lack of affordable housing, fragmented pockets of development, limited infrastructure, criminal activities, gentrification and areas of poor living conditions- the Inner City has the capacity to intensify and realise the growth needs through spatial planning and development systems to develop a vibrant core of the city.

Furthermore, this study relied on the mixed methods approach that allows layering of various methods and methodologies in data analysis and collection. It employed both the qualitative and quantitative methods. Purposive sampling was applied to identify key informants from all relevant institutions including the University of Johannesburg, City of Johannesburg and Housing Development Agency. Snow Balling was used for identifying municipal officials that specialize in spatial planning and developmen department of the city. In addition, both the stratified sampling and convenience sampling were also employed to select participants in the human settlement programme and housing delivery for the study in the Housing Development Agency. The city of Johannesburg and Housing Development Agency share housing delivery programmes within the city, currently they have adopted a priority project of closing the housing gap and title deeds backlogs. Therefore, Stratified sampling was then applied to sample each individuals into sub-groups to investigate their consumer satisfaction of housing delivery, tenure security and standards of living within the portions of the city.

5.1 Data Collection methods

Both the primary and secondary data types were collected to inform this study, through employing various data collection techniques including conducting interviews with officials, distribution of survey questionnaires, field observations, desktop study using literature sources and municipal documents to guide the research.

5.1.1 Survey Questionnaires

According to De Vos & Fouche (1998), questionnaires are research instruments that are composed of open or closed questions or statements to which a respondent must react to. For this study, questionnaires were structured in an objective manner and consisted of four sections each, of which were categorised on the objectives set for this study excluding the profiling of demographics for participants. A total 100 questionnaires were distributed electronically to the municipal officials who are responsible for land use planning and development, also 50 questionnaires were distributed to community leaders and citizen within the jurisdiction of the city of Johannesburg.

5.1.2 Interviews

Formal interviews were conducted with relevant key stakeholders of spatial planning and development in the University of Johannesburg, City of Johannesburg and Housing Development Agency. The interviews were conducted through Zoom and Microsoft teams in order to adhere with covid-19 regulations set by the South African government. The interview questions varied across the participants, the first badge of questions were specifically on spatial planning and development within the city and the second badge focused on quality of life, human settlements and service delivery. Professor Trynos Gumbo who is serving as the Head of Department for Urban and Regional Planning at the University of Johannesburg was engaged in this study as the potential spatial planning researcher and involved in consultation stages for development of spatial development policies of the city of Johannesburg. Ms Nokuthuka Thusi (Director: Land Use Development) in the city of Johannesburg was interviewed, whom is identified as the relevant stakeholder involved in influencing spatial planning, land use and management of the city of Johannesburg. Chief town planner in Housing Development Agency was interviewed for his role in human settlement development in the city, Mr Leroy is involved in drafting of Regional Spatial Development Framework for the city.

5.1.3 Literature sources

Extensive reviewof legislative and policy frameworks such as SPLUMA, IUDF, SDF, IDP was conducted to track the efforts taken by the city to improve quality of life through inclusive and effective spatial planning systems. Also, key scholarly journals focusing on areas of spatial planning were used for information relating to studies done previously on the analysis of the city.

6 RESEARCH FINDINGS

This section of the study presents the research results of the efficacy of spatial planning and development systems in improving the standards of living of the communities in the City of Johannesburg. The section further integrates the research results with objectives and aim of the study and apply the research results to draw up conclusions and recommendations. The argument of this study is based on the understanding that the City of Johannesburg is the driving force of economic development in Gauteng, South Africa and Southern Africa, which is why the city is associated with active economic growth, high urbanisation rates, poor service delivery and opportunities that comprehend the quality of life. Johannesburg spaces are hubs for innovation, science, infrastructural development, commerce and culture including challenges that may hinder the city from developing sustainable development frameworks, creating jobs, enhancing quality of life for communities etc. Primarily, Johannesburg continue to prove legacy of spatial segregation, development fragmentation, poverty and exclusion of socio-economic opportunities. Therefore, there is need to assess the extend to which spatial planning and development systems can be utilized to improve the standards of living in the city.

6.1 The current state of spatial planning and land-use development in the city

The regional map of the City of Johannesburg divides the city into seven (7) various regions, however, for the results of this study greater attention is focused on Region F of the city which is made up of the inner city (Central Business District). Below in figure 6.1 is a spatial representation of the inner city and various land uses as well as the current development implementation.

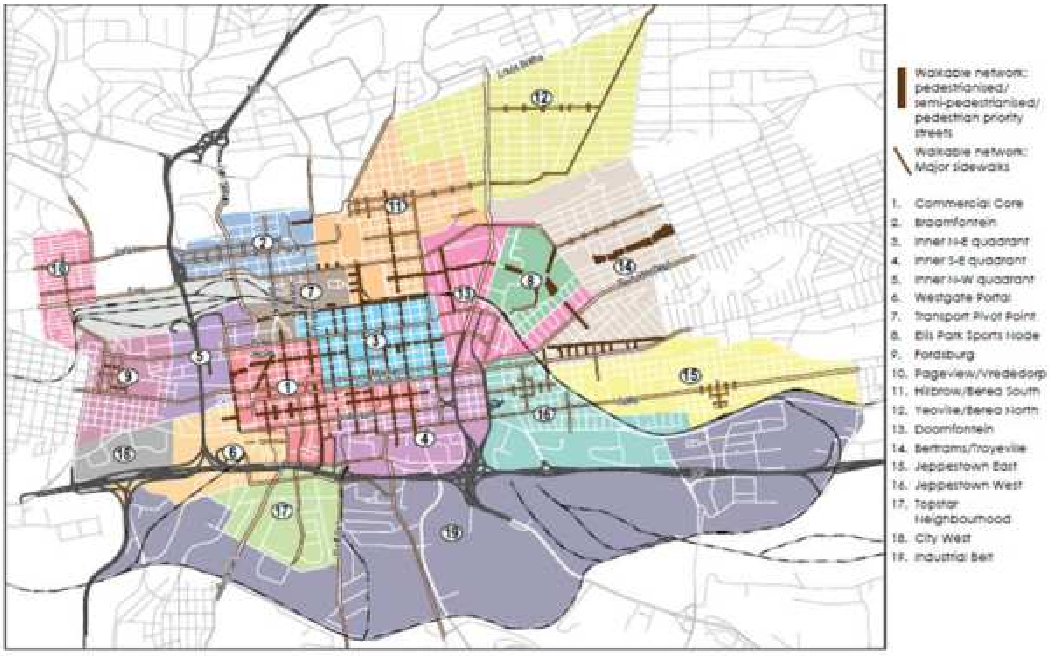

Figure 6.1: The spatial representation of the inner city of Johannesburg. Source: City of Johannesburg Municipal Spatial Development Framework (2016/17)

The inner city of Johannesburg is planned and developed into various land-uses, this is influenced by one of the justifications of municipal spatial development framework which emphasis mixed-land use development in the city to address the past spatial injustices of spatial segregation, development fragmentation, lack of connectivity etc. Above in figure 6.1, it is represented that across various areas of the city there are portions of mixed-use development mainly consisting of residential, business, commercial, recreation, industrial, municipal, transportation etc. This type of development continues to prove the commitment of the city to employ tools of spatial planning and development to improve the quality of life in the city. Over the past years, the city of Johannesburg has been earmarked the most growing city in the SADC region and economic hub of South Africa based on the development systems adopted by the city.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

6.2 Challenges that hinder appropriate living conditions and Urban transformation

The National Development Plan (particularly, Chapter 8: Transforming Human Settlements) and Integrated Urban Development Framework (IUDF) emphasis that spatial planning and space development in cities are the primary priorities for reducing inequalities, poverty, unemployment and managing high urbanisation rates in South Africa. The city of Johannesburg is faced with urban challenges of high urbanisation rates, basic service delivery, high rentals and unemployment (specifically youth unemployment) which require intervention at a city-level and other organs of the state. Prioritizing spatial planning initiatives, targets, development investments, plans and sustainable legislative frameworks can assist the city in strengthening economies, boost quality of life through creation of employment, social inclusion, spatial justice and sustainable development.

Through engagements with municipal officials using interviews and questionnaires, it is safe to conclude that the City of Johannesburg is confronted with massive spatial paradox, where socio-economic development investments tend to intensify existing spatial segregation and developments fragmentations, particularly in urban areas. The city of Johannesburg demonstrates the need for institutional coordination in various parastatals of the local government to enhance the city's spatial transformation vision as envisaged in Municipal Spatial Development Framework.

6.2.1 Service Delivery

The city of Johannesburg through its spatial planning and development tool, Integrated Development Plan (IDP) that is reviewed annually, committed itself to provide adequate access to basic service delivery across all households of the city. The basic service delivery in the city of Johannesburg is currently high with the number of households in both (formal and informal areas) having access to sanitation (96.4%), electricity (92.3%) and piped clean water (98.8%) in 2020.

Service	Households Serviced %	Approximate Backlog in Households	Backlog %
Housing (formal dwellings)	75.1%	448 200	24.9%
Water	98.8%	22 200	1.2%
Sanitation	96.4%	66 601	3.6%
Electricity[19]	92.3%	133 540	7.7%
Refuse removal	92.9%	131 352	7.1%

Figure 6.2.1: Service delivery and backlogs in the city of Johannesburg. Source: City of Johannesburg Integrated Development Plan (2020/21)

The city has a total of 1.8 million households currently in 2021 and of these households, the aforementioned service backlogs have been realised (refer fig 6.2.1 above): formal dwellings (24.9%), Water (1.2%), sanitation (3.6%), electricity (7.7%) and refuse removal (7.1%). These backlogs are a cause for concern because there continues to be evidence of a deficit, specifically in informal settlements in which less than 50% of the households have access to basic sanitation.The following backlogs are manifested by the high population growth in the city and expansion of informal dwellings developing from illegal land invasions which have led to almost 211 informal areas between the years 2016 and 2021 (Oranje, 2014).

6.2.2 Too many Spatial planning and development strategies

There are multiple planning and development strategies introduced at the national, provincial and city-level which may derray the focus of development goals, due to contradiction of one another. For example, the NDP has realised the negative impacts that its inefficient spatial arrangements impose on the urban poor group and introduced the new spatial transformation that transform economic activities and livelihoods for the poor, while reducing high levels of urbanisation (National Planning Commission, 2011). Meanwhile, the city of Johannesburg used the Transit-Oriented Development as a tool to fight spatial inequalities to bridge the gaps of jobs-housing mismatch. The corridors of freedom strategy which is a resultant of the Joburg 2040: Growth and Development Strategy is the spatial vision of the city to allow the urban citizens to have increased freedom of movement and allow people to live closer to economic opportunities and allow accesss to jobs or places of learning to the unemployed groups also bring school learners closer to the schools in the city (City of Johannesburg, 2014). Too many strategies and legislative frameworks of spatial planning and development may contradict each other, address spatial visions differently and introduce different approaches on how to deal with transformation which is a setback for sustainable development goals. There is a need for uniform and single priority strategy that address development and spatial planning across various cities and the country regions.

6.2.3 Proliferation of Informal Settlements

The majority of informal settlements in the city has been developed before the year 2000 with approximately 135 settlements erected already after this record, there were no new informal settlements developed after the year 2003 (Oranje, 2014). Currently, statistics shows that the percentage of the city's households living in informal areas is below 7.51%. According to Housing

Development Agency Status Report (2016), there has been a greater increase in the number of population residing in formal dwelling within the city of Johannesburg since the year 2001. Between 2000 and 2001, almost 77% were residing in formal dwellings, by the year 2011 this number has increased to 81.5%. In addition, the number of households residing in shacks and not backyards has decreased by 8 228 form atleast 125 750 over the period of ten years meanwhile the number of households living in shacks instead of backyards has decrease to 9% in 2011 from 13.1% in 2001 (Gauteng Dept of Human Settlements, 2015). According to Census (2011), the city of Johannesburg has recorded a database of 180 informal settlements across various regions of the city.

6.2.4 Transportation challenges

The city of Johannesburg is faced with numerous mobility challenges. There are key public transport interventions and implementation introduced such as Gautrain system (project invented provincially) and Bus Rapid Transport (Rea Vaya) system (project led by the city), they both play an important role in a new era of inclusive mass public transit between regions of the Gauteng province and at city-wide level. However, the utilization of these modes of transport is relatively low as compared to other existing modes of transport such as the minibus taxi system which consume 45% of the city‘s commuters. Even thou the minibus taxi industry is proven as unreliable, unstable and normally associated with violence, criminal activities and use of poor quality of routes. This effect has resulted in 28% of the residents using their private cars with aorund 4% to 0.5% people using Rea Vaya BRT or metrobus as well as Gautrain (Turok, 2014). In this regard the city's sector for transport continues to lead with 38% in terms of carbon emission as compared to other sectors including the industrial sector with 28% and residential sector with 26%.

6.2.5 Unemployment in the city

Despite efforts of growth over the past ten years and the city of Johannesburg's status as the economic engine of the national economy adding to 16% of the country's GDP, the city economy still show traits of unequal city economies in the world. Formal employment have not matched the standard of the GDP growth, given that only 12% of formal job opportunities were traced in the city and currently the city's unemployment rate is at 32.7% with youth unemployment estimated to be above 40% (City of Johannesburg IDP, 2020).

Based on figure 6.2.5 above, it is shown that unemployment rate in the city of Johannesburg in 2019 was estimated at 26.5%, which has increased with 3.19% in a period of one year from 2018. The unemployment rate in Johannesburg is relatively low as compared to the provincial rate of Gauteng. In 2018, South Africa recorded unemployment rate of 27.18% which shows an increase of 3.59% from 23.60% recorded in 2008. Meanwhile, currently unemployment in Johannesburg is recorded at 32.5% in the year 2021.

6.3 The implications of adopted spatial planning and development systems in the City

The city of Johannesburg first development its Growth and Development strategy in the year 2006 as a strategy for long-term development path for the city. During this time other strategies were in place such as Joburg 2030, Human Development Strategy (HDS), City safety strategy and the Integrated Transport Plan. Currently, the city development the Joburg 2040 Growth and Development Strategy which provides an opportunity for the city to consolidate all the spatial planning and development systems into a single cross-city strategy. This strategy also serve as a guideline to the conceptual foundation of the five-year Integrated Development Plan of the city.

The Growth and Development strategy, 2040 is an effective strategy that seeks to identify the type of the society that the city aspires to attain by the year 2040 (City of Johannesburg, 2011). Nevertheless, The

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Joburg Growth and Development Strategy 2040 is a contemplate for medium-term, strategic and spatially-oriented plans of housing, infrastructure, transport sectors and service delivery. Furthermore, this city Growth strategy does not delegate/outline the functions, operational activities and institutional powers. On the other hand, it directs a set of strategic guidelines that shape the five-year city IDP together with other supporting medium-term plans.

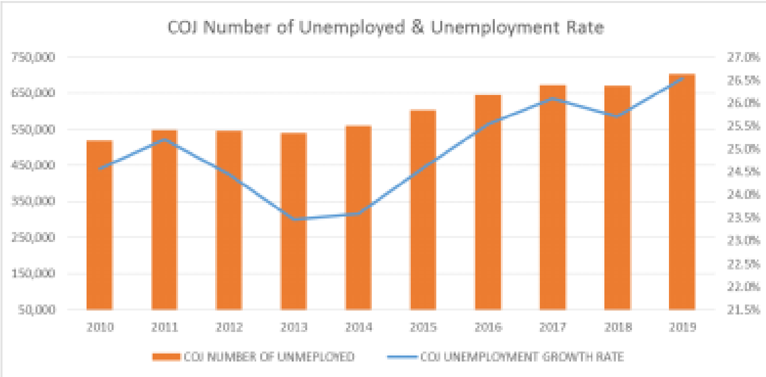

Figure 6.2.5: Unemployment Rate in Johannesburg. Source: City of Johannesburg IDP (2020/21)

The city of Johannesburg Spatial Development Framework 2040 (SDF) is known as an adopted city-wide spatial policy document that outlines the main city challenges and spatial development opportunities derived within the city, sets out a spatial vision of the metro and identifies the strategies to achieve the visions set by the city. This spatial policy document advocates for transformation zones which include the areas that are prioritised for investment to deal with future urban intensification, urbanisation and urban growth. The transformation zone also outlines areas where the development of informed spatial plans and visions will be prioritised, especially previously spatially disadvantaged areas such as townships.

The SDF emphasis the strengthening of the metropolitan core employing various measures such as Inner City Transformation Roadmap, Transit-oriented Developemnt, Inner City Housing Implementation Plan and improvising on the opportunities of the City centre as a congested economic hub of the city and addressing arising challenges such as fragmented spatial development, criminal activities, lack of affordable social housing, delayed service delivery etc. This strategy is based on developing a compact precincts of inclusive mixed use development densification surrounded by public transit and economic opportunities. In addition, the implications of this strategy is to support support economic nodes in the Inner city through different interventions such as investment programmes in engineering infrastructure and social facilities (Ebrahim, 2017).

The Corridors of Freedom strategy as envisaged in the Joburg 2040 Growth and Development strategy prioritize measure of consolidating development and urban growth opportunities around the current and future transport nodes, which are mobility spine to the city starting from the Corridors of Freedom integrating Soweto (South Western Township), through the Central Business District to Sandton (along the Louis Botha Ave and Empire-Perth) and also integrating Turffontein into the CBD. This strategy enhance the focus towards the Transit-Oriented Development nodes such as Rea Vaya (Bus Rapid Transit), PRASA and Gautrain stations. The vision of the corridors of freedom is to transform the entrenched patterns of settlements within the metro which have placed the majoirty of the citizens to the outskirts of the city, where there are no economic opportunities, access to adequate housing, jobs and growth. This strategy aims to increase the norm of people-oriented city where the needs community needs, comfort and socio-economic well-being are at the core planning of the city.

7 CONCLUSIONS AND RECOMMENDATIONS

Spatial planning and development systems shape the urban built environment, on the other hand, the built environment dictates the extent to which cities are sustainable, productive, inclusive and well developed (Harrison & Todes, 2015). This study is centred around assessing the efficacy of spatial planning and development systems in improving the living conditions of the society in the city of Johannesburg, throughout the study the city space was examined closely as the epicentre of understanding the state of the city in terms of the status-quo of quality of life, service delivery, land use planning and development strategies that are applicable to the city. However, the spatial configurations of the city have been altered by various dimensions of development such as inclusivity, finances, governance, productivity and sustainability.

Using various methodologies of data collection, i.e interviews, questionnaires, desktop tools, observations and others; the study realised the immediate urban challenges which require greater attention in the city such as addressing urban sprawl, exclusion, development fragmentation, unemployment, transport issues, proliferation of informal settlements and inadequate service delivery. Therefore, the city need to change the perception of solo-driver in the functions and activities that inform spatial change, there is a need for collaboration across various stakeholders in making decisions of the space as well as development.

The Joburg 2040 Growth and Development Strategy provided an initiative of Transit-Oriented Development (TOD) through the Corridors of Freedom programme, the TOD strategy has the capabilities to consolidate and transform zones around the inner city that requires spatial redress and justice through integrating the peripheral, poor settlements/townships with mixed-use, nodal development of industries where the economic and social opportunities exist. The findings of this study reveals that the land use in the City of Johannesburg is predominantly assigned for residential, industrial, business, commercial, recreational etc, which are nodal development requirements to promote economic growth, improved quality of life and facilitate sustainable development. The Land-use management and spatial planning approaches in the city should facilitate a direction for prioritising human well-being, economy, residential activities and investments.

There is an urgent need to apply measures and empowering instruments that enable participation of the urban communities in finding solutions to their urban challenges through active engagements with the city officials and other relevant stakeholders. In order to address these urban challenges of urban sprawl, proliferation of informal settlements, lack of connectivity, high urbanization rates and poor service delivery; there is a need to reflect on the effectiveness of the current spatial planning and development legislative frameworks and strategies, identify their critical gaps and progress in terms of achieving the desired society and urban development in the city (Integrated Development Framework, 2016).

To improve the standards of living in the city, attention should be given to spatial policies that drives the development of infrastructure, economic growth and social inclusion. This can be attained by making sure there is an adequate public participation in decison-making of developments in their space, also foster relationship between the informal and formal sectors of economy to boost the economy and livelihoods of the urban poor. High urbanisation rates and Proliferation of informal settlements can be dealt with by decentralizing small-scale activities to the outskirts such as manufacturing activities.

(Prof. Hany Ayad, Alexandria University, hany.m.ayad@alexu.edu.eg)

1 ABSTRACT

Planning of cities during this decade is oriented to car use, and therefore physical environment that encourages physical activity in the streets is neglected and drastically affected. Studies showed that features that have the strongest effect on residents differ from a community to another depending on culture, social norms and others. This paper identifies the built environment factors that have the most significant influence on engaging residents to physical activity in Alexandria City, Egypt. It also investigates the barriers and facilitators that the residents face while commuting the city. In this study two surveys were conducted, the first (survey I) assessed the value and frequency of participation of residents to physical activity in Alexandria city and identified the specific facilitators and barriers that affects their participation in any kind of physical activity. The second survey (survey II), followed the International Physical Activity Questionnaire – Long Form (IPAQ-LF) to measure the current level of the residents' physical activity. The two surveys are complementary and both revealed the relationship between urban environment features and the associated impacts on physical activities of residents. The results demonstrated the level of physical activity of residents, the satisfaction level of main features with a photo demonstration and locations that affect the ability to frequently engage in physical activity in Alexandria city. It is resulted that urban and street design is the highest motivator that could increase the physical activity of residents. The "availability of open and green areas" has the least satisfaction level from residents, but it is the highest influencing facilitator for physical activity. "Congestion of streets", "lack of time" and "pollution" are from the significant barriers that reduce the engagement of residents in any form of physical activity.

Keywords: Physical Environment Features, Facilitators and Barriers, Satisfaction, Physical Activity Engagement

2 INTRODUCTION

People living in cities are facing various barriers and challenges to being physically active every day. According to Frank and Engelke (2001), urban planning was dominated by a strong focus on cars for decades. The widespread implementation of car-oriented land use and transportation developments have ignored or underestimated the underlying public health consequences. In such environments, where there is heavy reliance on car use, people spend more time on travelling instead of on health-improving activities. This is now changing to a focus on creating cities for people. Today's current concern in cities is to plan urban environments that are responsive to the citizen's everyday needs, improve their quality of life and maintain their health.

Relationships between physical activity and health status are more and more recognized in the literature (Ulijaszek, 2018). The Transportation Research Board and Institute of Medicine (2005), indicated that although individual engagement in physical activity results to some degree from personal choice, it is also a function of the built environment. Researchers and practitioners have come to appreciate the importance of the built environment in facilitating or constraining walking and physical activity (Saelens & Handy, 2008). Salvo, M. Lashewicz, et al. (2018), Ivory, et al. (2015) and Belon, et al. (2014), among other researchers suggest that the physical environment has an influence on the physical activity of people. Thereby, the physical environment can operate as a barrier, a facilitation condition, or contextual influence and the way we build our cities, design the urban environment and provide access to the natural environment can be a great encouragement or a great barrier to physical activity and active living (WHO-Europe, 2006). With the majority of the population living in cities, it is sensible to look at how urban environments have changed, influenced lifestyles, and contributed to the increase in overweight and obesity (Frumkin, 2002). It is challenging, yet essential to develop a better understanding of the features that mostly influence the physical activity.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

2.1 Physical activity status in the Middle East and Egypt

Evidence suggests low levels of physical activity among arab adults living in Middle Eastern countries. According to the WHO (2014), barriers to physical activity in the Eastern Mediterranean Region include competing family demands, such as childcare and household chores; long working hours; heavy school workloads; other competing priorities, such as socializing; lack of affordable leisure facilities; lack of outdoor spaces, such as parks, to be physically active; inadequate public transport systems and heavy reliance on cars; lack of 'walkable' neighbourhoods; feeling unsafe; and climate.

2.1.1 Status in Egypt

In 2009, A Survey of Young People in Egypt (SYPE) by the Egyptian ministry of planning, monitoring and administrative reform with contribution from the Population Council and the Central Agency for Public Mobilization and Statistics (CAPMAS) was conducted for the first time. A second round of the survey was conducted in 2014. The survey concentrated on youth of ages between 10 and 29 and focuses on key aspects of their lives including education, employment, health, family formation, migration, reproductive health, social issues and civic/political participation.

These survey included a series of questions asking about their daily physical activities, including biking and walking, going to a gym, playing sports, or physical work on the job. The results showed that nearly half (45.8%) of SYPE respondents do not engage in physical activities daily. Nearly twice as many young women (59.2%) did not exercise as men (33.3%). SYPE participants aged 13-17 were more likely to indicate daily exercise (66.8%) than the those aged 30-35 (49.0%).

This can be attributed to the lack good streetscape in most of the streets in Egypt as indicated by Rehan (2013), where this adversely affects the behavior of users and esthetic aspects of built environment, and thus deterioration of the visual image of most Egyptian cities. Other reasons for less engagement of physical activity is what Traill (2006) stated, which is that people engage less in physical activity due to urbanization, the sedentary nature of jobs, as well as the speed and convenience of driving rather than walking or biking. All these features promote an unhealthy lifestyle with low physical activity levels specially that being physically active is not common in Egyptian culture. This contributes to a sedentary lifestyle and consequently, to obesity and various non-communicable diseases.

2.1.2 Urban Environment in Alexandria City

According to Elsawy et al. (2017), Alexandria city witnessed an evident shift during the last few decades due to its rapid urbanization. This has contributed to numerous urban, social and environmental issues; such as traffic congestion, environmental pollution, decrease in green areas and degradation of the urban quality of living

As a consequent to rapid urban densification and population growth in the past recent years, the problem of squatting has occurred. The speedy construction of illegal 20-story high rise apartment blocks (Fig. 1) in major cities in public defiance and violation of building laws caused high population density, which jam traffic flows and burden services and utilities beyond their limited capacities. All these problems have had a mass effect on the individual's health (physically, mentally and physiologically) (Zahran, 2014).

Fig. 1: High apartment blocks

Another kind of squatting that appeared fiercely, was the infectious infiltration of venders squatting and invading sidewalks (Fig. 2 and 3), squares, streets, public parks and public land, forcing pedestrians to walk in the streets and to mingle chaotically with cars. The common use of sidewalks by shop owners, cafeterias, coffee shops (Fig. 4), repair shops, and garages had become a familiar scene, compounded by their habitual occupation by parked cars (Fig. 5,6 and 7), by vendors and rural women selling their produce. This congestion is multiplied by unruly car owners who park their cars illegally in two and three rows on street lanes, especially in city centres and near shopping malls, thus causing traffic snarls and strangling jams (Zahran, 2014). All are considered as barriers for physical activity because people experience very hard times to walk comfortably on the sidewalks.

Fig. 2,3 and 4: Invasion of sidewalks by restaurants and vendors

Fig. 5, 6 and 7: Cars parking on sidewalks and pedestrian paths

This study aims to identify and develop a better understanding of the built environment features that have the most significant effect on the residents and accordingly influence their engagement in physical activity levels in Alexandria City, Egypt. The study also explores the barriers and facilitators that the residents face while commuting in the city.

3 METHODS AND TOOLS

According to Welk, G. (2002), physical activity can be assessed using objective or subjective methods. Objective methods such as accelerometer, pedometer, motion sensors, heart-rate monitors, etc are used as they are easy and small wearable monitoring devices that objectively measure physical activity under free living conditions, yet they do not provide information about the type of activity. Subjective methods such as surveys, questionnairs, diaries, etc. are the most commonly used in studies as they are inexpensive, a reliable alternative in a large sample size and they capture more detail about a diverse range of physical activities which enriches more the data collected. Technological advancement devices such as: GPS devices are used in measring physical activity because they track the route of individual and can assess actual travel behavior, yet compimentary methods are needed with it to specify type of physical activity. McKenzie, (2002) point out that direct observation exceeds other measures of physical activity in providing contextually rich quantitative and qualitative data, especially with regard to the what, when, where and with whom it occurs.

Measuring built environment has also been achieved in studies through various methods and tools. Geographic Information System (GIS), offer accurate indicators (Brownson et al. 2009). Observational audits are also from the efficient methods in studies. Lately virtual observational audit tools such as “Visual STEPS ” and “Google Street View (GSV)” were used in studies Steinmetz-Wood et al.(2019), but according to Lafontaine et al. (2017) they do not incorporate sensory inputs such as noise levels, soundscape, and scent that may contribute to a pedestrians experience of a streetscape. Photo-voice methods, focus groups, face to face interviews and surveys are also from the commonly used methods.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

3.1 Adopted Methodology Framework

To fulfil the main aim of the research paper, the methodology framework adopted investigated how the built environment features in Alexandria city can affect the engagement of resident in physical activity. The features selected for this study cover not only urban aspects, but also social (such as: support from family and friends), and safety aspects (like: from crime, injury and accidents). They are proven to have an effect on residents' physical activity in previous studies such as: Bellows-Riecken et al. (2013) and Belon, et al. (2014). Features like "lack of time", "traditional dress" and "cultural lifestyle" are also selected in the study to cover sociocultural aspects because according to Donnelly, et al. (2018) they are also reported as reasons that hinder physical activity.

This study adopts an analytical framework that started by screening the available tool and methods for measuring built environment and physical activity of residents in previous studies. This step was followed by implementing the selected methodology for the study. The selected methodology comprised two complimentary surveys. Survey (I) assessed the value and frequency of residents' participation to physical activity in Alexandria city. It also measured their current satisfaction level towards 9 determinants (e.g.: quality of streets and sidewalk, availability of green areas, opportunity to walk for certain destinations, for leisure and exercising, opportunity to bike, the availability and quality of public transportation). The survey also identified the specific facilitators and barriers that affects the participation in any kind of physical activity in addition to an onsite observation took place to locate the urban environmental features mentioned in the surveys with photo demonstrations. After collecting the responses of residents, relative weighing analysis method was applied in order to: a) Arrange the 9 determinants in order of the residents' satisfaction level, from the determinant with the highest satisfaction level to the lowest, b) arrange the facilitators and barrier features from those having the highest influence on residents to the lowest.

Survey (II) followed the International Physical Activity Questionnaire – Long Form (IPAQ-LF) to measure the current level of the residents' physical activity in Alexandria city. Hagstromer et al. (2005) indicated that most existing questionnaires focus on physical activity during leisure time or at the workplace, which limits the use of these instruments. Only a few of the existing surveys capture physical activty in a variety of daily situations, such as transportation, occupation, household and family care, and leisure time A key feature of the IPAQ form is its ability to provide, in detail, participation estimates for multiple domains of physical activity, including leisure-time physical activity, physical activity for transportation, physical activity in the home and physical activity at work (Craig, et al. 2003). Figure 8 below, is a diagram that demonstrates the adoped methodology framework.

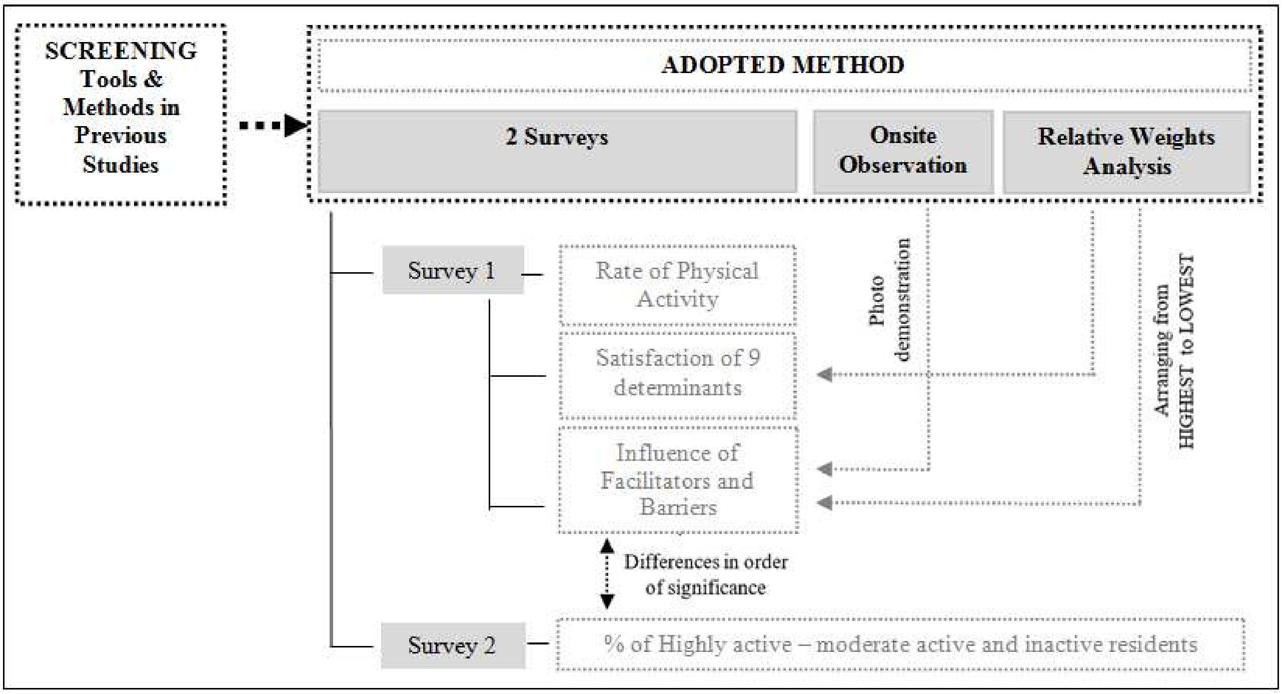

Fig.8: Methodology Framework Diagram of the Study

3.2 Sampling

The Survey targeted Alexandria residents in 6 age groups (>20 years, 22-25 year, 26-30 years, 31-40 years, 41-50 years and <50 years) through online google form (posted in Arabic and English languages) and was spread through social media channels. Most of the responses were from individuals under 50 years old. The survey accepted responses from residents until most variables were covered. Some elderly Alexandrians were intervieved personally.

3.3 Data Collection:

Survey (I) is divided into 4 parts, each part focuses on a particular issue for collecting the data.

- Part 1 is concerned with collecting biodata about the respondents, the value of physical activity to them relative to their other daily activity through a 5 likert scale, data about the respondets' rate of exercising and what motivation would increase that rate.
- Part 2 gathers data about the preferences and satisfaction of residents while commuting. Residents were asked to rate their satisfaction level towards 9 current determinants also on a likert scale from 1 to 5; with 1 for the lowest satisfaction and 5 for the highest.
- Part 3 explores 13 built environment features that would encourage and facilitate the residents to participate more in physical activity (i.e. facilitators)
- Part 4 concentrates on 13 barriers that hinders the residents from participating in physical activity.

Survey II collected data about the physical activity of residents using the IPAQ-long form following the "Guidelines for Data Processing and Analysis of the International Physical Activity Questionnaire (IPAQ)" in three domains; work physical activity, transportation physical activity and Leisure physical activity. Each domain is calculated separately, to scope the most dominant domain for physical activity of participants, then all domains were merged together to specify the respondents' physical activity levels (High, Moderate or Low). There is a fourth domian in the IPAQ long form which is concerned with the outdoor housework such as: gardening, yard work, shoveling snow and chopping wood. These kinds of housework are not common in Egyptian culture. Hence, Part 3 of the survey is excluded from Survey II.

3.4 Data Analysis:

3.4.1 Survey (I):

Responses of residents were collected, filtered and then analysed. Responses were then calcultated in percentages in order to determine : a) the value of physical activity, b) how often do residents exercise, c) reasons for not exercising regularly, d) motivations that would increase their engagement in physical activity, that were then grouped into 5 clusters (urban, personal, social, safety and economic), d) the satisfaction level of residents towards 9 determinants in the city, and finally e) the influence of facilitators and barriers that residents meet while commuting. The respondents were asked to choose the 5 most significant facilitating features (out of 13 feature) that would encourage them to walk more for leisure and for physical activity (part 4), and to choose the 5 most significant barriers (out of 13 barriers) that they meet while commuting in the streets for leisure or for physical activity (part 5). Then the satisfaction level and influence of facilitators and barriers (part 3,4 and 5) were arranged in order of satisfaction and influence by applying relative weight analysis to arrange them from the highest to lowest using the following equation:

Where, each of the corresponding 5-point scale rating was multiplied by the number of respondents who gave that rating, summing them up, and then dividing them by 5 (the highest point scale) and total number of respodents.

3.4.2 Survey (II) - International Physical Activity Questionnaire – Long Form (IPAQ-LF):

To calculate the total physical activity according to the IPAQ Guidelines for the data processing and analysis of the International Physical Activity Questionnaire (2005), the data were transformed into energy expenditure estimated as the total metabolic equivalent (MET) using published values and recommendations from the IPAQ scoring protocol. To calculate the daily physical activity in MET minutes per week, the number of minutes/day reported in each activity level was multiplied by number of days/week then multiplied by its specific MET score (MET-minutes per week: minutes of activity/day x days/week x MET

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

score). MET scores were as follows: walking/light Physical activity = 3.3 METS, Moderate Physical activity = 4 METS, Cycling for transportation= 6.0 METs and Vigorous Physical activity = 8 METS

IPAQ is available in two formats (short and long forms). An important difference between the long and short forms of the IPAQ, the IPAQ long form provides information about time spent in physical activity for each domain, whereas in the short form, the outcome is only a total score for physical activity (Sebastia˜o et al. 2012). The Guidelines for Data Processing and Analysis of the International Physical Activity Questionnaire (IPAQ) (2005), divided respondents into 3 physical activity levels according to their total score (High, Moderate and Low).

- "HIGH" Physical activity is any one of the following 2 criteria: a) Vigorous-intensity activity on at least 3 days and accumulating at least 1500 MET-minutes/week OR b)7 or more days of any combination of walking, moderate- or vigorous- intensity activities accumulating at least 3000 MET-minutes/week.
- "MODERATE" Physical activity is either of the following 3 criteria: a) 3 or more days of vigorous-intensity activity of at least 20 minutes per day OR b) 5 or more days of moderate-intensity activity and/or walking of at least 30 minutes per day OR c) 5 or more days of any combination of walking, moderate-intensity or vigorous intensity activities achieving a minimum of at least 600 MET-min/week.
- "LOW" Physical activity (inactive) is when there is no activity reported OR Some activity is reported but not enough to meet the previous 2 categories (HIGH and MODERAT physical activity)

4 RESULTS AND DISCUSSION

Responses recieved from the surveys were 242 responses from both genders. They were divided into 6 age groups as mentioned earlier. Data collection indicates that the most responsive age group are the age from 31-40 years (42% of respondents). 55% of the respondents has a bachelor degree, 31% has master and Ph.D and the rest are university students. Of all respondents, 79% are employed and therefore they commute every day from home to their work locations. And so the results obtained are from an education level that can be relied on.

Motivation type	Responses	
1.Urban *a. Street Design: (35%)*	Availability of suitable sidewalks (flat, wide, continuous/unobstructed and well paved) to walk and exercise Availability of safe wide green areas, open spaces and gardens with pedestrian paths A place providing services and amenities such as seating Cycling lane	Presence of aesthetic mental image Removing vendors and coffee shops that are invading large spaces of the sidewalk Adequate lighting in the streets at nights Cleanliness Trees and shaded areas
b. *Proximity (5.5%)*	Places close from home	Having gym facilities nearby
c. *Traffic (3.3%)*	Less congestion in terms of cars Available of public transportation modes Presence of traffic light signs that allow pedestrians to cross safely	Away from vehicle noise Less car fumes Low speed of vehicles Fixed itineraries
2. Personal *(26%)*	Having more time Good weather Maintaining health, wellness and weight loss No crowdedness and comfortability	Suitable outfit Shopping Presence of places where practising physical activity is fun
Gym facility *(7.1%)*	Privacy and security Cleanliness Gym offering a kids safe area for children	Clean showers Places for girls only Guided classes in the gym
3. Social *(17%)*	Encouragement and support from friends or family	Having company Seeing people exercising in the street
4. Safety *(4%)*	Safe environment Not getting harassed	Keeping away from vehicles for safety
5.Economic *(1.6%)*	Presence of places with reasonable prices	

Table 1: Categorized Responses to Motivations of Physical Activity

4.1 Survey (I):

Results of part 1 of the survey shows that from the respondents, 38% valued the physical activity moderately (value of 3 out of 5), 34% valued physical activity highly (with value of 4 and 5 out of 5). As for rates of exercising, only 22% of respondents exercise regularly, 58% exercise "irregular/sometime" and 20% do not exercise. Results also indicates that men exercised regularly more than women (30% and 17% respectively).

This can be attributed to the traditional roles that women play within society, such as the responsibility for childcare and household chores, which may give them less time to participate in physical activity.

"The lack of time (45%)" and "the lack of places to walk, stroll or run comfortably (24%)" are the main reasons that is preventing the 20% that are not exercising from exercising regularly. "Cafes and restaurants invading the sidewalks by their tables", "not being used to regularly exercise" and "the lack of awareness of the importance of regular physical activity" are additional reasons that were added by the respondents. Table 1 (below) demonstrates some of the motivations that were mentioned by residents, they are grouped into clusters and represented in percentages. It shows that "urban" motivations, specifically the presence of suitable street design, have the highest percentage (35%) that motivate respondents to do more physical activity. This indicates that urban features in the city are the most important driver of physical activity which directly affects the general health condition, mental health and social affairs of residents. Following to Urban features, was the personal motivations as the second important motivator for physical activity.

Results of Part 2, are represented in Table 2 (below). It displays the 9 determinants, the satisfaction level of each and their arrangement in the order satisfaction levels (from highest to lowest) resulting from the relative weighting method. It depicts that the majority of satisfaction levels of respondents were low (varied between 1 and 3 on likert scale) which concludes that the determinants are not in the expected satisfaction level of residents and that futher analysis is needed inorder to identify the reasons for the dissatisfaction.

Fig. 9: Example to Green/open areas in Alexandria

	1 Low satisfaction scale	2	3	4	5 High Satisfaction scale	Relative weights	Arrangement (highest to lowest satisfaction)	
Availability of public transportation	16%	24%	30%	20%	10%	56.8	1	
Walking to a certain destination (near home)	16%	28%	34%	14%	8%	54.4	2	
Opportunity to walk for leisure	21%	32%	26%	14%	7%	50.8	3	
Opportunity to walk for exercising	38%	27%	19%	10%	6%	44.0	4	
Quality of Public transportation	32%	32%	27%	5%	4%	43.0	5	
Quality of streets	35%	31%	26%	5%	3%	41.8	6	
Quality of sidewalks (walking)	43%	30%	14%	8%	5%	40.2	7	
Opportunity to bike in the streets	51%	19%	15%	8%	7%	40.0	8	
Availability of open/green areas	51%	26%	14%	3%	6%	36.8	9	

Availability of public transportation	busses not available in all routes - no prompt scheduling
Walking to a certain destination	crowdedness - vandalism - pollution
Opportunity to walk for leisure	crowdedness –harassment (for girls) – Lack of adequate lighting – presence of obstacles - no green spaces - no spaces to walk freely and feel safe.
Opportunity to walk for exercising	Limited places (cournich street only or inside clubs)
Quality of Public transportation	not clean – no maintenance - people abuse it
Quality of streets	Always crowded – some traffic street lights doesn't work to cross safely
Quality of sidewalks (walking)	Narrow and high - used by shops/cafes - motorcycles uses sidewalks to park - presence of obstacles – no seating available
Opportunity to bike in the streets	Very dangerous to ride it in the streets with cars - can't ride on sidewalk
Availability of open/green areas	The public ones are not safe - not clean and no maintenance

Table 2: Level of Satisfaction of Respondents (%) and Relative Satisfaction Level. Table 3: Problems Faced by Respondents concerning the 9 Determinants

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

The 3 determinants that took the highest satisfaction level were: “availability of public transportation”, followed by “walking to near destinations near home” because residents are used to the surrounding around their homes, then the “opportunity to walk for leisure” as the third place. The lowest satisfaction level was given to the “availability of open/green areas” because open and green spaces are limited, and the available ones are either neglected or in remote places. Following to Table 2, some general reasons for the respondents’ rating in Survey (I) are displayed in Table 3.

Results of Part 3 and 4 demonstrates the order of features from highest to lowest influence on residents after applying the relative weighing analysis method (Table 4 below). This ordering helps deepen the understanding of the most significant features that affects the behaviour and physical activity of residents postively or negatively.

Table 4 reveals that the physical activity facilitators that have the highest significance is the “presence of trees and green areas”, this is because they provides a better environment for the residents. It makes them feels relaxed and calm instead of being surrounded by cars and fumes causing constant stress and uncomfartability. Hence, it is urgent to start taking more care and increase the urban and green spaces to raise its satisfaction level and therefore induce the physical activity of residents. Trees are more available in some of the streets to provide shade in sunny days, lower the temperature and gives a good surrounding atmosphere. This is why shaded areas came as the second facilitator. However, trees can act as obstacle at places with narrow sidwalks. The presence of “streetlights” was the third facilitator as some streets in Alexandria are not adequately lit, and that induces an unsafe feeling. “Feeling safe from injury or crime” is the fourth facilitators. The sense of safety is essential for one to move freely and comfortable in the streets. Finally “presence of sidewalk network” is the fifth facilitator as it gives the pedestrians their space to walk and enjoy moving freely and safely. This can also be achieved by: a) widening the sidewalks, because there are some places in Alexandria that have narrow sidewalks, and other places have no sidewalk to walk on, and b) removing the obstacles that are on the sidewalk such as vendors, cafe tables, cars parking on sidewalks

Fig. 10 and 11: Presence of Trees in Streets. Fig. 12: Trees as Obstacles in Narrow Sidewalks.

Significance	Facilitators	Relative weight	Barriers	Relative weight
Highest	Trees and green spaces	38.8	Congestion/crowdedness of streets	25.0
	Shaded areas	30.8	Lack of time	22.6
	Streetlights	27.6	Pollution	18.8
	Feeling safe from injury or crime	25.6	Weather conditions	12.8
	Presence of sidewalk network	25.2	Lack of facilities	12.2
	Presence of traffic signals and safe crossings	21.6	Culture and lifestyle	11.4
	Pedestrian only footpaths	17.4	No habit of exercising	10.0
	Presence of benches and seating	15.6	Dependency on cars	9.4
	Seeing other people walking	13.6	Lack of adequate public transportation	7.2
	Outdoor spaces, plazas and squares	11.0	Fear of Accidents	6.6
	Attractive buildings and views	9.6	Traditional dress dress not convenient for participating in physical activity	5.80
	Presence of shopping streets and restaurants	9.0	Exercise is painful	3.4
Lowest	Children’s playgrounds	5.2	Lack of support from family or friends	0.9

Table 4: Order of Significance of Facilitators and Barriers on Residents from Highest to Lowest

The barriers that have the highest significance is the “congestions and crowdedness of streets”. This is because crowdedness causes alot of noise and car fumes, and therefore stress and discomfort. All that repels people from any kind of physical activity. “Lack of time” is the second barrier. It was mentioned earlier (in part 1) that 45% of respondents chose it as one of the main reasons that is preventing them from doing physical activity regularly. This is due to the pressure and long hours that residents spend at work, also some people do more than one job in order to enance their economic status. Thus, they have no time for any physical activity. “Pollution” is the third barrier, and it is resulted from crowdedness and congestion of cars that already has the highest influence as a barrier.

4.2 Survey II - International Physical Activity Questionnaire – Long Form (IPAQ-LF)

After collecting and calculating the weekly physical activity of the respondents, it is found that 52% of the respondents are “Highly active”. This result was expected because most of the respondents (41%) were aged from 31 -40 years. 32% of the respondents are “moderately active” and 13% were “inactive”. The study explored the distribution of the respondents’ weekly physical activity in each of the 3 domains mentioned in IPAQ-LF (work physical activity– transportation physical activity– recreation and leisure physical activity), Each of the domains was divided into males and females for further analysis (Figure 2).

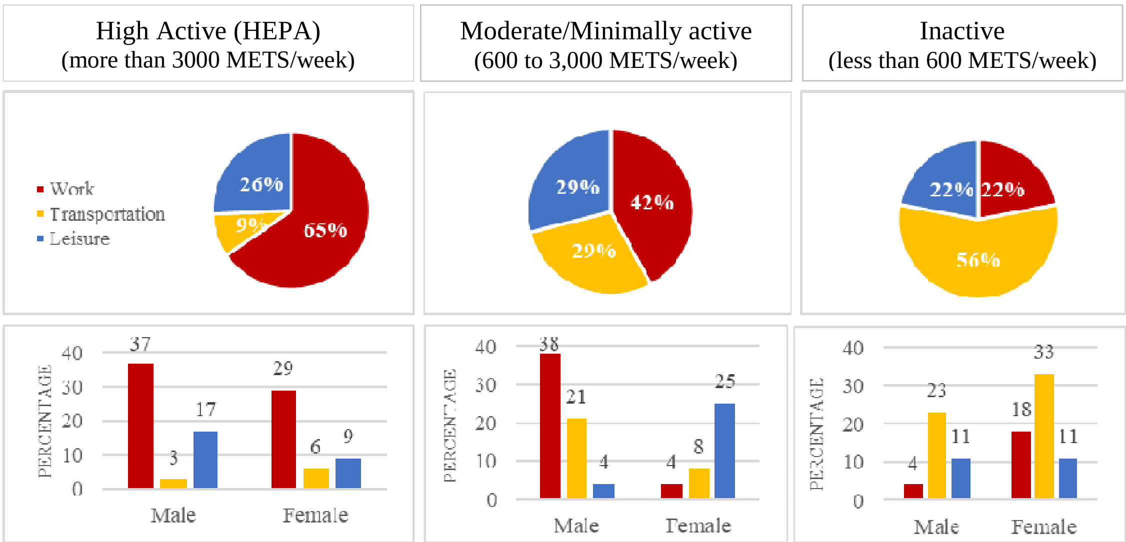

Fig. 13: Physical Activity Distributed on the 3 Domains of IPAQ-LF

From Figure 13, it is shown that most of the physical activity of the “Highly active” respondents are carried out during work by 65%, and the physical activity of males are slightly higher than females (37% and 29% respectively). In addition, the physical activity carried out during leisure and recreational time by 26%. Highly active males spend more time doing physical activity than females during leisure time (17% and 9% respectively) mainly because females already have other responsibilites during day time, such as taking care of children and constant housework, and so their leisure time is limited. Physical activity during transportation is the lowest for the highly active respodents (9%) because the highly active individuals pursue to be in constant movement. Males are less than females in this case, because men commute more than females.

For “Moderately” respondents, activity carried out during work also has the maximum pernentage by 42% of their total physical activities. The difference in physical activity carried out between males and females during work is very noticeable (38% and 4% respectively). Physical activity carried out in leisure time and during transportation were equal for “moderate active” respondents (29%). When comparing physical activity of males and females in both types of physical activity, it was found that males spent more time in physical activity than females during transportation (21% and 8% respectively), while females spent more weekly physical activity activity than males during leisure and recreantional times (25% and 4% respectively).

Physical activity during transportation attained the highest percentage for the inactive respondents (56%), as they do not do any activity willingly. Percentage value of females in work physical activity are more than that of males (18% and 4% respectively) and also in transportation physical activity (33% and 23% respectively).

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

When comparing the order of influence of facilitators and barriers between highly active, moderate active and inactive respondents, some differences were found. Figure 3 &4 shows these differences in the order of significance in percentages.

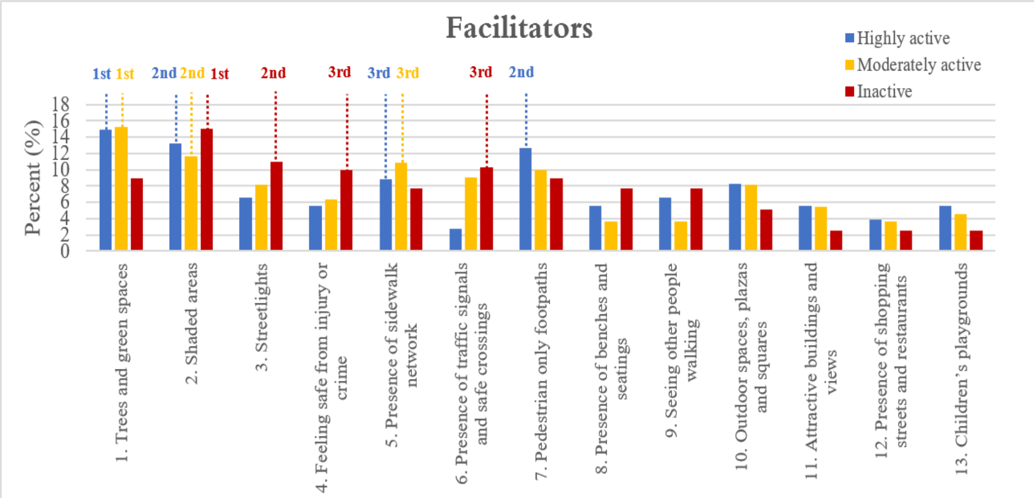

Fig. 14: Order of Significance of “Facilitators” between Highly Active, Moderately Active and Inactive Respondents.

Figure 14, shows that the order of significance of facilitators for the highly active and moderately active respondents are almost close to each other while the order is a bit different for inactive respondents. The facilitators with the highest percentage of significance is “trees and green spaces” for both, the highly active and moderately active respondents. “Shaded areas” received the highest percentage of significance for the inactive respondents, while it is second highest significant facilitator for the highly active and the moderate active respondents. “Pedestrian only footpaths” is also the second in order of significance for the moderate active respondents since people seek to walk around securely. “streetlights” is the second highest significance for the inactive respondents. “Presence of sidewalk network” is the third in the order of significance for the highly active and the moderate active respondents due to the ability of walking comfortably and safely. “Feeling safe from injury or crime” and “Presence of traffic signals and safe crossing” had the third significance for inactive respondents due to the assocaited sende of safety.

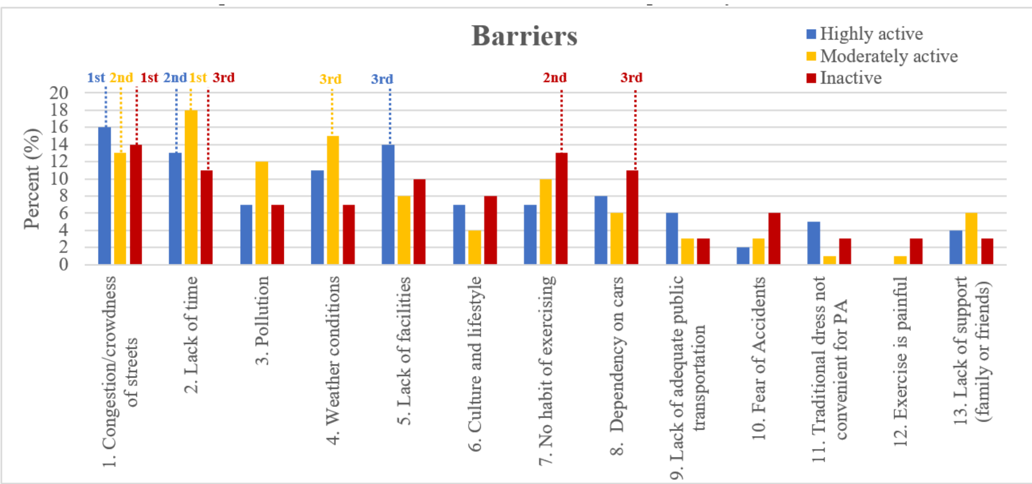

Fig. 15: Order of Significance of “Barriers” between Highly Active, Moderately Active and Inactive Respondents.

Figure 15 indicates that the barrier that has the highest percentage of significance from engaging in physical activity was “Congestion and crowdedness of streets” for both highly active and inactive respondents, it is the second in order for the moderately active respondents. “Lack of time” is from the significant barriers for the three types of respondents, due to long hours of work for residents and other responsibilities. It is the highest in significance for the moderately active respondents, second in order of significance for the highly active and the third in order for the inactive respondents. “No habit of exercising” is the second highest significance for the inactive respondents One of the main sociocultural reasons for that is because most of the parents concentrate on their children’s educational studies and neglect their participation in regular physical activity. “Lack of facilities” is the third in the order of significance for the highly active respondents, because availability of facilities is essential for their regular physical activity. “Weather conditions” is the third in the order of significance for the moderately active respondents, where good weather conditions give a push for physical activity in leisure time. “Dependency on cars” plays an important role for the inactive respondents because they mostly have no time to do any physical activity and so they do most of not all their chores using cars.

5 CONCLUSION AND RECOMMENDATIONS

The results of this paper indicated that walking decision depends mostly on urban motivations, and that urban determinants and built environment features affect physical activity of people both positively and negatively. It also shows that streets design parameters shape residents’ behaviour as they need to experience pleasure while commuting such as good scenaries, natural views, the presence of open and green spaces, network of sidewalks with no obstacles. Residents also seek to avoid any stressful factors such as crowdedness of streets, pollution and vandalism.

There are several features that act either as facilitators that induce individual’s physical activity or barriers that hinders individuals from engaging in physical activity and become more dependent on motorized transportation.

Conclusions of this study were found to be in line with most of the studies related to physical activity and its relation to urban determinants. Several recommendations are produced, and are directed to decision makers in local government. It is recommeded to:

- Consider highly open and green areas, as it has the highest influence as a facilitator for engaging in physical activity.
- Maintain the existing open areas with green spaces, and other shaded areas with trees to lower the temperature and provide a good surrounding atmosphere for residents and thus induce the physical activity of residents.
- Maintain street lights to enhance the feeling of safety while walking particularly in quiet places.
- Construct and maintain sidewalk network to provide the pedestrians with space to walk and enjoy moving freely and safely.
- Pay more attention to sidewalks to be well paved, with no obstacles on it and provide pedestrian footpaths or sidewalk networks for increasing physical activity in the streets.
- Consider highly the problem of vandalism that are invading the sidewalks. Once the sidewalks become walkable, it will attract residents to walk more often
- Increase public transportation to motivate people to use them more and increase their activity routine.
- Install bike lanes to help increasing physical activity, especially among youth. This will avoid risky situations of cycling in the crowded streets of Alexandria city.

1 ABSTRACT

Child-friendly urban spaces promote safe, independent and active mobility of children. This paper explores which indicators can be used to assess the quality of urban spaces in the context of child-friendly mobility. For this purpose, indicators from literature, guidelines etc. are collected. In total, 77 indicators are identified, described in terms of their relevance for child-friendly mobility and divided into four categories: (i) traffic situation and traffic conditions, (ii) urban space - infrastructure, (iii) urban space - amenities and other conditions, and (iv) other. For each indicator, very good (grade 1) and very poor conditions (grade 5) with regard to the quality of urban spaces in the context of child-friendly mobility are defined. A weighting is applied to evaluate the indicators according to their relevance for child-friendly urban spaces. In addition, a (more user-friendly) reduced set of 30 indicators is developed. The full catalogue of indicators, the subset and the associated evaluation scheme were used for an on-site inspection of a road section in the city of Vienna. The road section is also inventoried "digitally" based on geodata to analyze to what extent freely available geodata can be used to conduct the assessment without being on-site. By comparing the results (full set versus sub-set as well as manual versus digital assessment), the user-friendliness of the catalogue(s), the possibilities and limitations of a digital assessment of urban spaces in the context of child-friendly mobility are shown. The results show that processed indicator sets are suitable for the evaluation of the quality of urban spaces. In general, it can be stated that the results of the manual assessment agree very well with the entire catalog of indicators and with the shortened indicator set. The digital evaluation with indicator set also leads to comparable results, although outliers can also be identified for many "non-assessable" indicators. Due to a lack of data availability or quality, a (partially) automated digital evaluation is technically feasible, but many indicators have to be analysed or interpreted in-depth, which contradicts an automated evaluation. In the future, an automated evaluation of the quality of urban spaces in the context of child-friendly mobility could be possible and therefore offer a need for further research.

Keywords: child-friendly mobility, transport planning, urban spaces, indicators, children

2 INTRODUCTION

2.1 Starting point

The Federal Constitutional Law on the Rights of Children states, among other things, "Every child has the right to appropriate participation and consideration of his or her opinion in all matters concerning the child, in a manner appropriate to his or her age and development" (BVG Children's Rights, 2011). "Matters concerning the child" also include all those related to children's homes and living spaces. However, in urban or transport planning and related political decisions, children's opinion and specific requirements are usually secondary. Although comparably vulnerable road users, such as pedestrians and cyclists, are becoming increasingly important in cities' strategies (e.g. MA 18 - Stadtentwicklung Wien, 2015), existing spaces have been and continue to be used primarily for cars respectively car users. This contradicts the requirement that children as a particularly vulnerable group must be able to use public space safely and need to access their destinations to play and stay without barriers.

In addition to these ethical aspects, some worrying trends can be observed with regard to young age groups. In fact, one of that is the decline in physical activity: In Austria, only 17.4% of 11 to 17 year olds meet physical activity recommendations of the World Health Organization (WHO) (Maier et al., 2017). These low rates of physical activity are also reflected in the development of everyday mobility of children: Accordingly, results of the Austrian national household survey show that walking decreases by 15 percentage points between 1995 and 2013/14 for the age group of 6 to 14 years old children (Tomschy et al., 2016; Tomschy et al., 2017). At the same time, car-passenger trips increased by 12 percentage points. 36%

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

of education trips as car passenger are shorter than 2.5 km. Furthermore, studies in different European countries indicate that children's independent mobility is on the decline (Shaw et al., 2013, Shaw et al., 2015). These developments clearly show that urban spaces need to be designed in a way that active and independent mobility is promoted.

2.2 Child-friendly mobility

The quality of urban spaces in the context of child-friendly mobility cannot be considered one-dimensionally. Many factors simultaneously influence whether children can move, play and stay in urban spaces on foot, by bicycle, scooter, inline skates, or skateboard. This refers, for example to spatial / structural, social, and economic factors.

Spatial characteristics refer to the traffic situation in the vicinity (e.g., speed limits), presence of parked vehicles, existence of barriers such as roads heavily used by motorized traffic within walking distance, or noise pollution, to name a few (Blinkert et al., 2015). They include private areas (e.g. type of house, presence of a garden/(front) yard) as well as public areas (e.g. distance of the front door to the street, existence of green areas, playgrounds). When collecting indicators in this field one can make use of studies on walkability which have recently been published around the globe (e.g., Zuniga-Teran et al., 2017; Kostovasilis, 2013; Wey & Chiu, 2013; Khder et al., 2016; Leslie et al., 2006). However, one must take into account that children and adolescents have different demands on their (built) environment than adults. Exemplarily, while walking trips for adults are primarily relevant for errands and recreation (Leslie, et al., 2006), for children it is playing and meeting friends (Blinkert et al., 2015). This results in different requirements for the design and equipment of public spaces. In addition, child-relevant factors for other travel modes such as bicycle, scooter, etc. must be identified. Several Austrian guidelines are an important basis for the collection of indicators on child-friendly mobility in this study. Those guidelines contain recommendations, mainly in the spatial context; they are, however, not exhaustive. The guidelines "RVS 03.04.13 - Child-friendly mobility" (FSV, 2015) and "RVS 03.04.14 - Design of the school environment" (FSV, 2016). Another guideline on child-friendly transport planning and design, was published by the former Federal Ministry of Agriculture, Forestry, Environment and Water Management (BMLFUW, 2014). Another important basis is also a study of Blinkert et al. (2015) which has investigated how areas can be described and evaluated in terms of their qualities for children and what influence the residential environment has on children's play and everyday life.

Besides spatial characteristics, social and economic aspects influence the amount of free time spent outside by children, most of them indirectly via selection/distribution to favorable or unfavorable residential areas. These include f.e. the parents' level of education and the social climate in the neighborhood. In addition, the economic resources of the family, the family status of the parents (single parent or both parents), the employment of the parents, and an existing migration background all influence the unsupervised time spent outside the home.

It can be summarized that there are many factors which are difficult to capture in their entirety. In this work, only spatial and structural characteristics are considered.

2.3 On-site inventories

Spatial characteristics to assess child friendly mobility can be collected by on-site inspections / inventories conducted by observers (see for example Blinkert et al., 2015). Maps and photos can also be used to support the data collection. However, walk-throughs are time-consuming. Therefore the question arises, to what extent it is also possible to obtain information on the basis of existing geodata on a small scale. It could also be helpful to make assessments by combining objective data (GIS, open data) with data from on-site inventories. The development of automated evaluation tools would help cities to address the challenge of assessing socio-ecological qualities of urban spaces and to promote livability.

2.4 Objectives

Based on the starting point and challenges described, this paper deals with an evaluation of urban spaces in the context of child-friendly mobility. The main objective is to investigate which indicators can be used to assess the quality of urban spaces in the context of child-friendly mobility. A user-friendly set and evaluation scheme should be developed. Bases on on-site inspections in the city of Vienna the applicability is to be tested. In addition, it is analyzed to what extent freely available geodata can be used to conduct the assessment without being on-site. By comparing the results (full set versus sub-set as well as manual versus digital assessment), the user-friendliness of the catalogue(s), the possibilities and limitations of a digital assessment of urban spaces in the context of child-friendly mobility are shown. The paper is structured as follows: In section 3 the approach is described. In section 4 the full catalogue of indicators is presented, the weighting procedure and the limitations. Based on that, the sub-set of indicators and the digital evaluation are presented. Section 5 presents the results of the application of the evaluation procedure. In section 6 conclusions are derived.

3 APPROACH

A multiple step approach is used to address this complex topic:

In a first step, relevant factors are researched based on guidelines and other literature. This results in a compiled list of indicators for assessing urban spaces in terms of child-friendly mobility. These factors can have an impact both directly and indirectly by influencing each other. The majority of the indicators have an effect through the reduction of motorized traffic, the reduction of motor vehicle speed and the creation of good visibility conditions in urban areas. In addition to road safety, some indicators also have an impact on subjective perceived social safety, but also on other aspects such as aesthetics of urban spaces. This, in turn, affects parents' decisions to let children go outside unsupervised.

In a second step, the list is summarized and shortened to a sub-set of 30 indicators to make it possible to evaluate individual street sections quick and simple.

In a third step, this sub-set of indicators and the associated evaluation scheme are applied for three different road sections in the city of Vienna. The application is carried out both "manually", that is, by walking and assessing the conditions on site, and "digitally", that is, by means of available data and computers.

4 INDICATORS

4.1 Catalogue of indicators

Based on literature, 77 indicators were identified. Two thirds of them are mentioned in several sources and largely overlap in content. Although studies contain a description on the positive or negative effect on child-friendly mobility, in the majority of cases no detailed information can be found regarding the indicator’s expression in order to lead to this effect. This leaves a lot of room for interpretation as well as for the evaluation of the indicators. Although there are indicators that belong at least partially to private space (e.g. "type of house", "presence of gardens") they are nevertheless included in the catalogue.

The collected indicators are divided into four categories: (A) traffic situation & conditions, (B) urban space - infrastructure, (C) urban space - amenities and other conditions, and (D) other. Tables A1-A4 (Appendix) contain the description of all indicators, references, and (if available) specific recommendations. Most of the recommendations found in literature are qualitative; only occasionally (additional) quantitative information can be found. In principle, the aim should be to evaluate each indicator as objectively as possible. It seems, however, sometimes unavoidable to subjectively assess the indicators. For the evaluation, a five-part rating scale was used. The scale points were defined with 1 - very good, 2 – good, 3 – average, 4 – poor, 5 - very bad. For the endpoints (very good and very bad conditions with regard to child friendly mobility) a verbal description is given (Tables A1-A4, Appendix).

4.1.1 Category A: Traffic situation and traffic conditions

Current traffic conditions are summarized under this category; this concerns information on cross-section design (e.g. dimensioning of cross-section elements), traffic organization (such as legal regulations like the speed limit) and the prevailing traffic situation (e.g. compliance with the speed limit, traffic volumes, share of trucks). The indicators of this category can be considered together as "k.o. "-criteria for child-friendly mobility - conditions that must be met in order to achieve desired goals. This means that a majority negative rating in category A, cannot be outweighed by indicators of other categories. In total, 19 indicators are assigned to this category (Table A1, Appendix).

4.1.2 Category B: Urban space - infrastructure

This category contains 26 indicators regarding the infrastructural design which can promote safe, independent and active mobility of children (Table A2, Appendix). In contrast to category A, indicators of category B have a supporting but not decisive effect on child-friendly mobility. Examples include selective elements such as crossing aids, traffic light signal systems with green times adapted to the walking speed of children, floor markings, pictograms, or the combination of structural measures for traffic calming. Many indicators identified in literature differ only slightly. For example, four different indicators for the implementation of crossing aids can be found.

4.1.3 Category C: Urban space - equipment and other conditions

Indicators of category C allow to evaluate the local conditions that are not directly related to traffic. A total of 27 indicators are assigned to this category (Table A3, Appendix). The equipment of the urban space can especially contribute to child-friendly mobility, if indicators of categories A and B are evaluated positively. For example, private spaces such as the type of house (e.g., single-family home), or the presence of a yard may have a positive effect on children's unsupervised time spent outdoors (Blinkert et al., 2015), and thus particularly on active and independent mobility. In addition, low air pollution, low noise pollution, and seats in public space may promote active, independent mobility. However, if traffic conditions or infrastructure (A, B) are otherwise poor, these criteria have little influence on children's freedom of movement.

4.1.4 Category D: Other

This category includes 5 criteria that cannot be assigned to any other category, but find mention in literature several times (Table A4, Appendix). They include many different effects at the same time - for example, opportunities for interaction with peers, or the connectivity of the urban space. Strictly speaking, the expression of these indicators results from the effect of other indicators.

4.2 Weighting

A weighting procedure was applied to be able to evaluate the indicators according to their relevance for child-friendly urban spaces. We propose (i) an intra-category rating of the indicators and (ii) a category weighting. For the intra-category weighting, each indicator is assigned a weighting factor of 1 to 10, with 10 representing the strongest weighting based on the findings collected in the literature and a subjective assessment of Neuhauser (2020). These weighting factors are used to determine the percentage by which the respective indicator is included in the overall category result. The indicator "traffic volume (motorized)" receives the highest weighting with a prioritization of 14% in category A. In category D, all five indicators are considered equally important and are therefore all assigned a weighting factor of 1 (corresponds to 20% each). The weighting factors are included in Tables A1 to A4 (Appendix). A category weighting is additionally introduced. According to Neuhauser (2020), the findings of the literature review underline that the traffic situation and traffic conditions have the greatest influence on the child-friendliness of urban spaces. Urban space infrastructure is less significant, but still has a stronger impact on child-friendly mobility than urban space amenities. Other indicators only have a minor impact on the overall result. Thus, the proposed weighting clearly prioritizes category A (Traffic situation and conditions) with 55%, followed by category B (Urban space infrastructure) with 25%, category C (Urban space amenities and other conditions) with 15%, and category D (Other) with 5% (Neuhauser, 2020).

4.3 Limitations of the catalogue

4.3.1 Number of indicators

An attempt was made to include all indicators evident from the literature in the catalog. This leads to a complex list of 77 indicators. This contradicts the demand for a tool for “quick” and “easy” assessment of urban spaces.

4.3.2 Similarity

Since all indicators based on literature are included in the catalog, some of them differ only slightly. As an example, “curb extensions as crossing aids” and “roadway narrowing” are mentioned. Both serve mainly to improve the visibility of other road users, although narrowing the carriageway can also lead to a reduction in speed. By grouping similar indicators together, multiple mentions in the list can be countered, although care must be taken not to lose any relevant information.

4.3.3 Qualitative information

It is striking that there are much more indicators in category B and C than in A, although the traffic conditions are much more important in the assessment of the child-friendliness of urban spaces. It is equally striking that there are only qualitative recommendations and descriptions for most of the indicators. Only for six indicators specific recommendations for measures are discovered. This is logical in that urban areas differ greatly from one another. There are only a few recommendations for traffic regulation and infrastructural design and equipment that are valid for different urban areas. For example, it can be stated as a general rule that a speed limit of 30 km/h is better than a speed limit of 50 km/h in terms of child-friendly mobility. The situation is different, for example, with the indicator "presence of planting (e.g. trees, hedges)". Thus, it makes no sense to assume that a tree every 20 meters is "better" than a tree every 50 meters. Many indicators interact with each other and can only be evaluated in their entirety. It follows that the assessment of many indicators must be made subjectively and the urban space must be considered as a whole. However, this makes it difficult to derive specific recommendations or to assign the indicators to individual user groups such as pedestrians or cyclists.

4.3.4 Impact assessment

It is difficult to distinguish whether indicators affect children's safe, independent and/or active mobility. It is assumend, that if an indicator has a positive effect on safe mobility, children move more independently because they are allowed to. If children move independently, this inevitably leads to higher level of active mobility. It is not examined if children in better rated urban spaces have higher rates of active mobiliy. It is only evaluated based on literature whether the expression of the respective indicator has a theoretically positive/negative effect on child-friendly mobility.

4.3.5 Loss of information through "digital" evaluation

Additional information may be lost through the digital assessment. For example, if the presence of a pavement is determined via a digital data, no statement can be made about its quality. It is possible that the pavement is not sufficiently dimensioned so that vehicles can drive over it and it does not lead to more child-friendly conditions. This circumstance can only be taken into account by on-site inspections.

4.3.6 Incompatible combinations

Some of the indicators are interdependent (e. g. "presence of playgrounds" and "playground equipment"), but not all of them can be combined with each other (e. g. "presence of median islands as structural crossing aid" and "pedestrian zone"). In this case, the respective indicator must be removed from the evaluation. By creating different lists for different frameworks, incompatible combinations of indicators could be avoided. For example, separate lists could be created for pedestrian zones, one-way streets, the school environment, or possibly also for different user groups such as pedestrians, cyclists, or scooter riders, which are equipped with different indicators and weightings.

4.3.7 Indicators not assessable

With each indicator that drops out of the evaluation as "not assessable", the weights of the remaining indicators change. A direct comparison of two urban areas/road sections is only possible based on indicators that form the "lowest common denominator". How many indicators must remain as the lowest common denominator is not investigated. It should be noted, that the omission of too many indicators can lead to a distortion of the results.

4.3.8 Transferability

In their present form, the indicators can only be used for the city of Vienna. The definitions of the indicators take into account the specific cityscape, the infrastructure and the legal framework. For the use of evaluations in other cities, countries or in the rural area, the indicators must be modified accordingly and adapted to possibly different circumstances. It must be checked, to what extent data are available for a digital assessment outside Vienna.

Full catalogue	Indicator	Subset
A1+A2	Restricted motorized traffic	A1*
A3	Existence of one-way streets	A2*

4.4 Subset of indicators

Based on some of the limitations mentioned above, the full catalogue is shortend to create a more suitable set of indicators for faster application. The most relevant indicators for child-friendly mobility will be retained; rather unimportant indicators are omitted. If possible, similar indicators are combined. This favors having fewer very similar or incompatible indicators in the list. However, the problem that mainly qualitative information is available and no statements can be made about the actual impact of indicators cannot be counteracted by creating the shortened indicator set. Likewise, the loss of information due to the “digital” evaluation and the problem of non-assessable indicators remains. The subset of indicators contains 30 indicators (Tables 1 to 4).

4.5 Digital evaluation

For the “digital evaluation” based on the indicator subset, different sources for free available geodata are used. Almost all indicators are assessed digitally via ViennaGIS. Only the indicators “sidewalk/walkway” and “noise pollution” are partially assessed using information from other data sources (data.gv.at; maps.learminfo.at). In addition, for each indicator, the quality of the data is reported. This includes whether the data can be assessed automatically and whether all information necessary for the assessment is included. The better the quality of the data, the faster and more accurate the assessment can be performed. Based on the quality of the data, indicators can be evaluated directly, after further analysis, or not digitally at all. Three quality levels are described:

- Level 1 data can be displayed automatically, i.e. “at the click of a mouse”: The data contain all information and details. An example is the indicator “presence of speed limits”; speed limits can be displayed clearly and directly for the entire urban area.
- Level 2 data are available, but need to be interpreted in more detail to allow an assessment. The data contain only partial information and/or need to be further processed or analyzed in more detail for the evaluation. This applies exemplarily to the indicator “structural crossing aids”. For example, sidewalk extensions or median islands are visible via ViennaGIS. However, these are not automatically displayed, but have to be identified piece by piece on the map. It may be necessary to review level 2 data again by performing a “virtual walk-through” (e. g. Instantstreetview.com) in order to be able to give a valid assessment. Another example is the indicator “playground” which includes not only the presence, but also the equipment of playgrounds. However, via the available data, it is only possible to determine where playgrounds are present, but not how they are designed.
- Level 3 data is not available or cannot be evaluated on a digital basis. For example, no data can be found on the lighting.

5 ASSESSMENT

5.1 Case study

The evaluation scheme is applied for three inherently homogeneous road sections in the city of Vienna by using the full catalogue as well as the subset on-site (Neuhauser, 2020). In this paper, only one example is presented. In a second step, the assessment is also conducted “digitally”. The use case described in this paper is Köstlergasse – a one-way street about 200 meters long.

Figure 1: Köstlergasse, Maps data: ©2021 Google Street View

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

It is located in the 6th district of Vienna and connects Gumpendorfer Straße with Linke Wienzeile. The on-site inspection took place in January 2020 and lasted about 120 minutes.

5.2 Results

Table 5 includes the average values of the assessment of the indicators per category (with intra-category weighting and unweighted) as well as the number of assessable indicators. The results are distinguished between on-site assessment (full catalogue, subset) and digital assessment (subset). For the digital assessment also the data quality is displayed. It should be noted that, strictly speaking, averaging across the indicators in the categories is not permissible. However, the median represents a strong coarsening, so that the mean is used as a good approximation.

Table 5: Average scores of child-friendly mobility, 1 (very good)-5 (very bad). **Quality level of data level 1 to 3, see chapter "digital evaluation"

The results show, that based on the on-site assessment, 88% of the full catalogue indicators and all of the indicators in the subset can be evaluated. The digital assessment is based on 21 out of 30 indicators. Overall, the selected road section is rated "good" to "average" regarding child-friendly mobility. The worst conditions are achieved in category C (Urban space – equipment and other conditions). Due to the tight space conditions and the inner-city location, Köstlergasse lacks open spaces, green zones, seating areas, retreats and the like. The results appear plausible, especially when compared to the results from applying the evaluation procedure to other road segments, e.g. a pedestrian zone (Neuhauser, 2020). Comparing the total scores, the results of the on-site assessments agree well. With the full catalogue of indicators, values of 2.90 to 2.95 are determined; with the shortened set of indicators, values of 2.85 to 2.97. The overall results of the digital evaluation based on the sub-set are 2.35 to 2.68 and therefore differ by about 7% from the "on-site" result. This can be attributed to the higher scores in category B and D with rather low numbers of assessable indicators. The results in category A differ only slightly from each other; this category has the greatest influence on the overall result with 55% if the category weighting is applied. In fact, the data for the digital evaluation is only available to a limited extent (70% of indicators). In addition, some indicators could only be assessed inaccurately digitally. In total, level 1 data (highest quality) can be found for six indicators, level 2 data is available for 15 indicators. No usable data (level 3) can be found for nine indicators. Due to the poor availability and quality of the data, there is a large margin for interpretation. However, it should also be noted, that the digital assessment could be completed in about 30 minutes. Thus, the "digital approach" is 75% faster than the walk-through (120 minutes; arrival and departure not included). However, it has to be considered that the street section had already been walked before from the same observer and therefore the digital assessment could possibly be more time consuming for an unknown urban space. The walk-through is therefore significantly more time-consuming, although more precise results can be determined as a result.

6 CONCLUSION

The current study reflects the complexity of the assessment of the quality of urban spaces in the context of child-friendly mobility. Lots of indicators and criteria have been gathered from literature; some of them could be added in the Austrian RVS guidelines. As a result, a catalogue describes 77 indicators which are relevant for child-friendly mobility. However, the application of the full indicator catalogue is associated with limitations. By defining a subset (30 indicators), some limitations can be counteracted, but some remain. Comparable results are achieved, however, it should be taken into account, that this reduction of the catalogue is made subjectively. In addition, only the small-scale theoretical effects of indicators are evaluated. Effects outside the selected road section are not taken into account. More research is needed to test the assessment method for different road sections. This can help to verify the results stated above. As the weighting can have a significant influence on the results of the evaluation, experts could be involved to refine the weighting process. Furthermore, before-and-after evaluations (e.g. change of use of travel modes, of the share of independent mobility of children, of attitudes) in the course of the implementation of road redesign measures could help to assess the direction of action respecitvely the effectiveness of measures. Future research could also lead to more specific (quantitative) recommendations for the dimensioning and design of elements in the urban area.

The current study also shows that it is possible to evaluate urban spaces in the city of Vienna by indicators both manually by means of inventory and based on digital data. According to the subjective assessment of the observer, the results of the manual evaluation reflect very well the conditions found on site with regard to child-friendly mobility (Neuhauser, 2020). Although the evaluation based on geodata lead to comparable results, it seems, however, necessary to critically review the results determined in this way. In particular, the availability and quality of data is a challenge as most of the data belong to quality level 2 or 3 and cannot be used without further ado. Decisive influencing variables can possibly be considered only insufficiently or not at all. Therefore, it should be kept in mind that a digital assessment brings not only opportunities but also risks.

Given sufficient availability of data, in the public sector, “child-friendliness” could be taken into account in the future, for example, in urban and transport planning with a similar collection of indicators or used to prioritize investments. By visualizing the quality of urban spaces in the context of child-friendly mobility in the entire urban area, it may be possible in the future to bring this to the attention of decision-makers. But also for the private sector, additional data may be available in the future and processed accordingly. Subsequently, it would be conceivable to weight the indicators online according to one's own preferences and to display the results for the entire urban area. In this way, parents and children could use smartphones to find out about child-friendly areas in their neighborhoods. Possibly, these results could also be linked to traffic models and real-time data. For parents, this could be decisive for choosing the location of their residence and thus subsequently also influence rents and real estate prices.

1 ABSTRACT

The Upgrading Informal Settlement Programme (UISP) has been identified as an approach to improve the lives of informal settlement dwellers with minimal interruption to their livelihoods and social networks. In addition, it has been recognised as a progressive approach in human settlements that moves away from the traditional approach of providing housing in the periphery of the city. This approach requires community participation to be at the centre of the development taking place within the settlement. Recent studies reveal that commonly, the state lacks institutional capacity to conduct effective community participation. The paper presents the results of an assessment of community participation in the upgrading process of informal settlements, as implemented at the Slovo Park. The study was conducted using a qualitative approach by means of in-depth interviews with the residents of Slovo Park to gather information on the possible impact of ineffective community participation during the UISP process. The paper reveals that community participation was ineffectively facilitated and this is reflective in the residents' lack of information pertaining the design layout of the future projects to be implemented in the settlement. Moreover, the paper highlights that ineffective community participation hinders residents of informal settlements from accessing self-provided adequate housing and results in provided basic services such as electricity, inaccessible to the beneficiaries due to their known socio-economic status. Results in this paper can be used to emphasise the importance of meaningful community participation for a successful UISP process.

Keywords: Community empowerment, community participation, informal settlement, in situ upgrading

2 INTRODUCTION AND CONCEPTUALISATION

Globally, the urban population is predicted to reach 6.5 billion by 2050 (Feleki et al., 2018). UN-Habitat (2010/2011) indicated that in sub-Saharan Africa, approximately 14 million people migrate to urban areas annually. According to Ragheb et al. (2016), of this number, about 61.7% live in informal settlements. It is acknowledged that in most developing countries, the existence of informal settlements is a representation of poverty trap. Residents of informal settlements often exist in conditions that expose them to health risks, lack of prosperity, unsafe and undignified way of life and over the years, this has been justified by their illegal occupation status (Talukdar, 2018). Despite over 3.6 million new houses built since 1994 through housing strategies such as Reconstruction and Development Programme (RDP) or Breaking New Ground (BNG), development and expansion of informal settlements have been a recurring problem in South Africa (Brown-Luthango et al., 2017). The growing demand for housing and urban infrastructure has been exacerbated by the sudden influx of people into urban areas especially in large metropolitans such as Cape Town, Johannesburg, and Ekurhuleni (Møller, 2007). It is undeniable that the various strategies to eradicate informal settlements including demolitions and evictions have failed to cease the development of informal settlements.

According to Huchzermeyer (2014), BNG projects under the National Housing Subsidy Scheme also came along as informal settlement eradication strategy in which households qualifying for the once-off capital subsidy were often removed from the informal settlement and relocated to an identified suitable land where completed units were allocated. Although this programme provided many poor communities with low-cost housing, residents were disadvantaged due to the relocations to the peripherals of the city, where economic opportunities are scarce. It was recognised that this housing subsidy strategy was only dedicated for developments on vacant land, which presented a policy gap in terms of the availability of subsidy system designed to facilitate in situ upgrading of informal settlements (Huchzermeyer et al., 2014). Although Upgrading of Informal Settlements Programme (UISP) was initially launched in 2004, together with the BNG, implementation has been insufficient because it lacked political support. However, it was considered the most progressive housing policy to achieve integrated sustainable human settlements with minimal interruption to people's livelihoods. Implementation of UISP become apparent five years later, after the programme was introduced as Chapter 13 of the National Housing Code and National Upgrading Support Programme (NUSP) was incorporated to promote and support the implementation of UISP (Huchzermeyer et al., 2014).

Not only was this an attempt to close the policy gap, it was also an acknowledgement that informal settlements are a part of the urban topography and have the potential to address the increasing housing backlog (Wekesa et al., 2011). In situ upgrading of informal settlements has been regarded as an approach with minimal disruption to the livelihoods and social networks of informal settlement residents while improving their living conditions. Any upgrading intervention including UISP should consider the socio-economic status of the informal settlement to enable provision of basic services that can be accessible to the beneficiaries. UISP requires that there be a proactive community involvement in addressing their own developmental needs (Del Mistro & Hensher, 2009). The role of community participation in the UISP process is to ensure better planning and increase efficiency during the project, ensure that communities' real needs and issues are reflected upon, resulting in better cost recovery after the completion of projects. Furthermore, it enables skills transfer, ensure effective use of resources and ensure affordability (Marais & Krige, 1997; Marais & Ntema, 2013 and Wekesa et al., 2011).

Community participation in the planning process of in situ upgrading goes beyond just allowing community members to make decisions on the suitable product (Meredith & MacDonald, 2017), it can also be a key tool to enhance the community's self-reliance which could encourage innovative self-built or upgrade of their housing structure (Georgiadou & Loggia, 2016). However, Ziblim et al., (2013) observed that in practice, community participation is an administrative façade comprising of arranged meetings, with experts already designed and finalised plans, thus allowing little room for community participation and influence. Public officials often avoid real participatory processes in project planning, because they assume that these are not only "time-consuming," but also, can be "unpredictable" and "messy" (Ziblim et al., 2013).

Recent literature (Mathekga & Buccus, 2006; Ntema et al., 2018; Wekesa et al., 2011; Ziblim et al., 2013) only focuses on the lack of institutional capacity to facilitate real community participation which results in unsuccessful in situ upgrading of informal settlements. However, there has not been enough attention on the impact of ineffective community participation on the beneficiaries of upgrading processes. Given the gap in literature, the study assessed the barriers and opportunities of community participation and possible impact of ineffective community participation, with specific focus to the upgrading process of Slovo Park informal settlement. Subsequent sections of this paper highlight the review of related literature, the methodology adopted, the results, and based on the findings conclusions are drawn.

3 LITERATURE REVIEW

3.1 The history of South African housing and informal settlement upgrading

The South African post-apartheid government inherited a housing backlog from the apartheid regime. However, since 1994, the housing backlog has worsened and continue to grow especially in the major cities (Moola et al., 2011). A democratic South Africa resulted in the sudden influx of people into urban areas especially in large metropolitans such as Cape Town, Johannesburg, eThekwini and Ekurhuleni. With growing population, the demand for housing and urban infrastructure accelerated beyond the metro's capacity to keep up with the pace (Møller, 2007). The first approach to curb the housing backlog under the new democratic South Africa was through the RDP which focused on ownership and delivering starter home on a plot of land for the poor, with the target to deliver 1.6 million units by 2004 (Ojo-Aromokudu, 2013). According Esteri (2018), the first 1 million housing units were targeted to be delivered in the first 5 years since 1994. This appeared to be too much concern on the quantity of housing delivery while quality was compromised. The launching of BNG in 2004 was a shift from quantity to quality, presenting a comprehensive plan to developing sustainable human settlements. The key objective of BNG was to eradicate informal settlements, yet in 2018, 14 percent of the urban population was recorded to be living in informal dwellings (Esteri, 2018). Despite over 3.6 million new low-cost housing built since 1994 through the traditional subsidy-linked housing programme, development and expansion of informal settlements have been a recurring problem in South Africa (Brown- Luthango et al., 2017). In 2014, South Africa had a housing backlog of 2.3 million, this backlog was further estimated at 2.3 million in 2018, increasing with around 178 000 units yearly (Esteri, 2018).

It is argued that RDP and BNG have had unintended housing policy outcomes as it is evident that they are not successfully curbing the housing backlog, there is slowdown in delivery; inadequate housing has been delivered and continued growth of informal settlements in the major metropolitan cities (Ojo-Aromokudu, 2013). Both policies haven been largely criticised for their lack of inclusion of community participation and common practice of relocation of residents of informal settlements. These housing policies have undermined the livelihoods and existing fragile social networks of the poor and have perpetuated the apartheid urban planning strategies which have marginalised the poor (Cirolia, 2017). It became clear that the conventional model and largest subsidised housing programmes were not cost effective, inflexible and environmentally unsustainable and this presented a policy gap in terms of the availability of subsidy system (Huchzermeyer et al, 2014).

Upgrading Informal Settlement Programme was regarded the first progressive housing policy which promote in situ upgrading of informal settlements in suitably located land with minimal disruptions to livelihoods, social networks and minimal relocation while enhancing community participation (Huchzermeyer, 2014). Although UISP was introduced in 2004 through the BNG, there was insufficient political will and consensus to operationalise the incremental upgrading approach. Yet, through UISP, incremental provision of essential services for informal settlements can achieve immediate relieve residents of informal settlements are in desperate need of and it is cost effective (Misselhorn, 2017). However, since the incorporation of UISP into the Chapter 13 of the National Housing Code and NUSP in 2008, the country has witnessed pilot projects of in situ upgrading aiming at achieving National Development Plan 2030 (NDP) Outcome 8 'Human Settlements' – upgrading of 400 000 households in informal settlements by 2014 (Huchzermeyer, 2014). NUSP's main task is to promote and support the implementation of the UISP in terms of co-ordination with sectors and partners involved as means to ensure that government's capacity and professional practitioners is strengthened to implement community-based incremental upgrading, mainly in the metropolitan cities (NUSP, 2015). When implemented, UISP can benefit many amongst the 2700 informal settlements that have been developed over 2 decades ago as temporary transit camps or reception areas and have since been awaiting formalisation and incremental provision of basic services (Huchzermeyer, 2014). Nonetheless, it is evident that the target to upgrade 400 000 informal settlements in well located land by 2014 could not be achieved and it is argued that ineffective community participation and partnership have been a major impediment to effective in situ upgrading (Misselhorn, 2017).

3.2 Community participation in in situ upgrading process

3.2.1 <u>Developing countries context</u>

Developing countries such as to mention but a few, Egypt, Nigeria and Kenya have undertaken an initiative to achieve the UN Millennium Development Goals (MDGs), Goal 7 Target 10, to expressively enhance the lives of more than 100 million informal settlement dwellers by the year 2020 (Ziblim et al., 2013). Egypt's approach to informal settlement was the incorporation of Participatory Development Programme in Urban Areas (PDP) on the Informal Settlements Development Facility (ISDF) in 2008. The PDP promotes the implementation of participatory practices in urban upgrading between local government and civil society organisations (including residents of the informal settlement) to ensure adequate service provision (Khalifa, 2015). However, ISDF review conducted by El Maabady (2015) indicated that there was no real community participation in the ISDF process. According to El Maabady (2015), although this upgrading programme was only focused on providing funding for the construction of housing units for the residents, this was done without taking into consideration the needs and socio-economic circumstance of the beneficiaries. As such, living in the provided units was a high-priced option for the poor and the non-provision of power supply resulted in many reinstating illegal electricity connection in the newly provided housing units (El Maabady, 2015).

Ineffective community participation in the Nigerian Re-development project has been a contributory factor for poor response to informal settlements. Although the re-development policy was focused on improving the quality of life of the residents of informal settlements, beneficiaries were largely dissatisfied with the standard of housing provided. As such, the government's purpose was defeated by the selling and renting out of the provided housing units. It was argued that the re-development project was a top-down initiation, thus a size one fit all strategy not precisely suitable for the informal settlement upgrade of Port Harcourt.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Furthermore, the upgrading project was planned and implemented without involving the residents as an important part of the project (Obinna, et al., 2010).

Kenya's Slum Upgrading Programme (KENSUP) of 2003 also suffered from the barriers and missed opportunities of community participation which consequently reflected disregard for the existing socio-economic circumstance of the beneficiaries. Although the initial project was to upgrade the Kibera-Soweto village, the housing units that were prearranged were accommodative to the middle-class standard and posed affordability challenges to the intended beneficiaries. The provided housing units consisted of a two-bedroom and a multi-story single unit unsubsidised mortgage that was intended to be rented out for beneficiaries to afford mortgage repayments. Many recipients leased their units and found alternative and affordable accommodation elsewhere, in poor living conditions. It is argued that the redevelopment "upgrading" strategy undermined aspects of affordability and tenure security, therefore, it is perceived as a suspension to addressing informal settlements and not a solution (Huchzermeyer, 2008).

3.2.2 Defining community participation and its significance

It is important to note that the shift to informal settlement upgrading is stimulated by mainly the growing demand for adequate housing and expansion of informal settlement. The urban poor have nowhere else to go and have found an alternative affordable accommodation commonly closer to their workplace. Over the years, they have managed to turn informal settlements into a functional space, often through illegal connection to water and electricity supply. When providing incremental upgrading of basic services, the municipality is building on what has already been built by the community in order to integrate the settlement into the town or city. For this to be achievable and sustainable, residents are to be made partners in the upgrading process and stakeholders in the town or city. Thus, community participation is a pre-requisite (Misselhorn, 2017). Community participation can be defined as a process where the concerned individuals are consulted, empowered, and influence the change that is meant to better their life (El Menshawy et al., 2011).

Although community participation is a process politician find to be forced on them and unfruitful because in many occasions, it becomes a platform for complaints and protests against non-delivery of services, but if conducted effectively, it can benefit politician too (Misselhorn, 2017). Meaningful community participation is crucial for the sustainability of the in situ upgrading post-implementation (El Menshawy et al., 2011). It also has the potential to achieve an everlasting collaboration between communities and government (Simone et al., 2005). Thus, community participation is a key principle of UISP, as such, funding is made available to municipalities and are encouraged to apply for additional funding for external capacity to support participation processes (NUSP, 2015). According to El Menshawy et al. (2011), capacity building, both on leadership skills and technical knowledge is imperative for an effective community participation.

3.2.3 Stakeholders in in situ upgrading initiatives

According to NUSP (2015), participation must be undertaken through ward committees, and or Community Development Workers (CDWs), ordinary members of the community and other relevant key stakeholders (e.g. NGO's and or expects in the field). It is from such a structure that community participation process can lead to municipalities making well informed decisions that are based on the real needs of the community they serve. Simone (2005) highlights that in situations were varied interests are to be delivered, community consultation presents an opportunity for invloved stakeholders to openly bargain or negotiate and renegotiate functional compromises allowing greater flexibility, creativity and effeciency in the planning process. There will be better understanding of government's intentions and resource limitations it works under and gain community's buy in into the project through inclusive decision-making. Although not everyone within the community may have interest in participating, but for the purpose of meaningful participation, it is necessary that everyone be afforded an opportunity to do so (Burns & Heywood, 2004). The involvement of the vulnerable groups in the key stages of the upgrading can promote community empowerment and capacity building, develop sense of ownership in the project rather than being passive beneficiaries (NUSP, 2015).

3.2.4 Good practice and stages of participation process

Whenever a development strategy is considered, including for informal settlements, government must consider the following participation practices that have emerged from court cases in South Africa; respect and partnership, meaningful engagement, individual engagement, mutual consensus, adequate consultation and active participation. Although all the other practices must be considered, meaningful engagement is at the core of UISP as it encourages that all parties involved (community and municipality) have an open discussion to reach favourable decisions. As such, it is no longer considered meaningful if decisions were taken before the discussion took place because community members would not have been treated as partners in the process (NUSP, 2015).

Participation is an ongoing activity that may vary based on different stages but must be included in the entire UISP process. However, it is most crucial during discussions about development plans of the community. There are 4 phases in the UISP process that require participation. Phase 1: Application – an opportunity for grassroot development where gathering information to assess and categorise of the community can be provided by the community members to form part of the pre-feasibility report. Thus, shared control or collaboration between municipality and community is required. Phase 2: Initiation – submission of the business plan will require cooperation from both the municipality and the community to ensure that the real needs of the end users are reflected. This can also be achieved at minimal consultation unless the community is of the opinion that unneeded project or business plan is drafted. Both application and initiation phase require all parties involved to participate because they involve much negotiation and decision-making, this is an important stage of participation. Phase 3: Implementation – due to the technical complexity, active community participation is rarely expected unless in a case where community involvement is optimal. Thus, the municipality takes full control of this stage. Phase 4: Consolidation – depending on the consolidation undertaken, participation will differ. If housing is provided through the subsidy, informed participation will apply but if there will be People’s Housing Process, the community will take full control (NUSP, 2015).

3.2.5 Participatory methods and techniques

Participation methods are not a size one fits all. The best method to choose depends on the purpose, the desired level of participation and the guiding principles. With respect to upgrading, community-based planning method is commonly recommended, but action planning method has proven to work successfully. Action planning has elements of community-based planning, therefore, goes beyond community-based planning. The aim of action planning method is to empower communities to design their project layout, undertake implementation process and manage their own upgrading projects (NUSP, 2015). This method is highly recommended on a re-blocking process, which is another approach to upgrading. Re-blocking has been a common practice under UISP as an initial indicator for interim intervention for informal settlements. Re-blocking aims at addressing issues of safety and unhealthy living spaces especially in very dense informal settlements (Tshabalala & Mxobo, 2014). Re-blocking process is a community-driven exercise which results in the reconfiguring or rearranging of shacks according to the community-drafted spatial framework. The community members are in full control of the process of negotiating floor sizes, tearing down shacks and creating a community-based plan, subsequently building a stronger social cohesion and solidarity (Moreschi et al., 2012). During this process, officials and other involved stakeholders have the privilege to gain wisdom and better understanding of the community’s perceptions by listening to stories, which form a significant part of a meaningful community engagement (Pinfold, 2015).

3.2.6 Challenges in the South African context

The South African challenges of community participation are not on the policy guidelines, but implementation. The principles of participation for informal settlement upgrading are clearly stipulated. Build common ground and knowledge between institutions and communities. This includes internal knowledge (life experience and skills) from the communities and external knowledge (technical and specialised knowledge) by municipalities and or specialists. Build mutual trust, make and deliver realistic promises. Stimulate engagement and communication that goes beyond the specific project deliverables, especially because post-implementation there is a continuous operating, maintenance, and urban management issues to address. Establish transparency during the entire process where the municipalities share information with the communities about problems, obstacles and challenges encountered including delays with funding or development approvals and do so as they arise. Perhaps some of these challenges can be dealt with collaboratively. Ensure that there is a community-based partner to effectively represent the community as this plays a key success factor (Misselhorn, 2017).

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

However, in practice these principles are not implemented, and this has a negative effect on beneficiaries. According to Mathekga & Buccus (2006), lack of community participation has characterised the post-apartheid South Africa over the years. Common reasons for the recurring culture have been the issue of lack of technical skills and lack of adequately trained personnel at local government level. However, this has been largely viewed as an indication that government undermines the importance and effect of active citizenship as crucial elements in a democratic setting, in which citizens should be recognised beyond just customers of social services. The numerous protests within communities are an indicator of dysfunctional relationships between citizens and government. Citizens are not well informed, particularly regarding participatory governance and public officials are yet to be educated on how to facilitate the process (Mathekga & Buccus, 2006). Thus, communities are not empowered with the knowledge and understanding necessary to make informed decisions. As such, instead of a meaningful community participation, in practice, communities play an advisory role. Top-down decision-making and planning of service delivery approach remains unchanged as participation by ordinary people is perceived as interfering with effective delivery of basic services (Thwala, 2009). In practice, community participation is an administrative façade comprising of arranged meetings, with experts already designed and finalised plans, thus allowing little room for community participation and influence. Public officials often avoid real participatory processes in project planning, because they assume that these are not only "time-consuming," but also, can be "unpredictable" and "messy" (Ziblim et al., 2013). An example would be the implemented in situ upgrading in the community of Makhaza (Khayalitsa) and New Rest (Gugulethu) Cape Town. The City of Cape Town only focused on the quantity of houses needed to be built and leaving little opportunities of open spaces for cooking stokvel, shop spaza, sewing groups, cultural activities, burial societies and socials which women in this community used as survival strategies, social interaction, communication and reciprocity. This was evidence of lack of participation and consultation with the community during the planning process and the City of Cape Town also admitted that designs commonly do not put additional consideration of women and their social networks (Massey, 2013). Informal settlement upgrading projects that were supported by NGOs such as Shack Development International (SDI) have been more bottom-up, grassroot approach of participation and have better responded to the needs of residents (Cirolia, 2017).

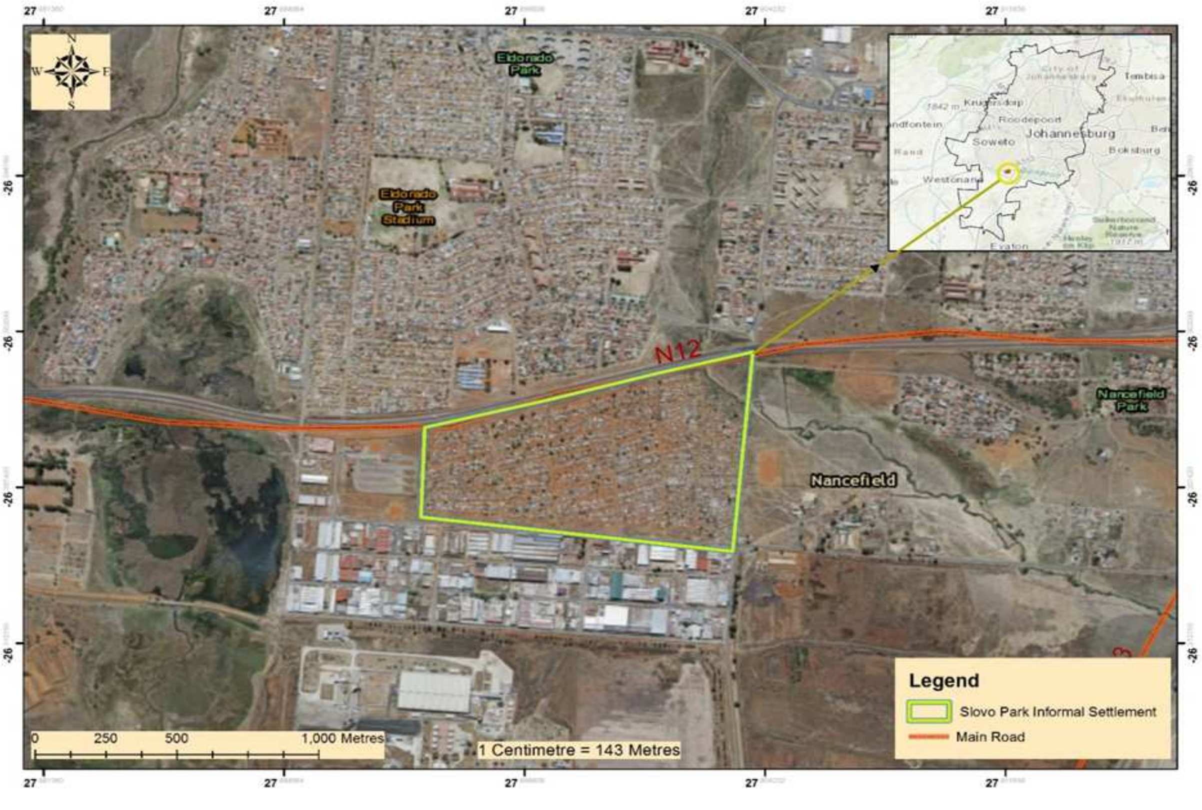

Fig. 1: Location of Slovo Park, Gauteng, Johannesburg.

4 UNPACKING THE CASE STUDY

Slovo Park informal settlement is in Johannesburg, Region G, next to the Nancefield Industrial area between Nancefield, Eldorado Park and Bushkoppies. The settlement was established in the early 1990s by mainly individuals seeking accommodation closer to their workplace and it has since been expanding (Tissington, 2012). In 2011, Slovo Park consisted of a population of more than 5000, about 1600 households amongst the 1 050 stands. There are no recent statistics of the total number of the population currently living in Slovo Park. Figure 1 below, displays the location of Slovo Park informal settlement within the Gauteng Province, Johannesburg.

Justification for this study area is that it is one of the oldest informal settlements in Johannesburg and recently received a favourable court ruling to have the settlement upgraded through the UISP. City of Johannesburg (CoJ) has submitted a business plan in application for UISP funding from Provincial Housing MEC. Nonetheless, Slovo Park is at Phase 3 of the UISP because incremental provision of basic services such as water supply, pit toilets, electricity and weekly refuse removal have been implemented. Therefore, "moving towards bulk engineering service provision which includes sewerage and storm water drainage, housing provision and roads" Respondent 1. As discussed in the previous section, phase 1 and 2 of UISP process are the most important stages requiring community participation and by the time in which the study was conducted, these phases have been concluded in the study area. This research focused on exploring the barriers and opportunities of community participation that took place during these phases as well as phase 3 and implications of ineffective community participation on the beneficiaries of the upgrading.

5 RESEARCH METHODOLOGY

The research objective is set out to assess the barriers and opportunities of community participation and the implications of lack of real community participation in the UISP process, studying Slovo Park informal settlement upgrading. This study is qualitative, thus, explores the objective of the study under investigation in the natural setting in terms of behaviours, varied perspectives, and life experience. In this study, in-depth interviews and field observation were conducted. Snowball sampling was utilised to identify ten interviewees that participated in the study, targeting specifically individuals older than 20 years, preferably the elder in the family, until sample saturation was reached. The researcher had purposefully selected ten interviewees consisting of ordinary community members, a community leader who is a local church pastor and member of the community development forum, and an additional two municipal officials. The collected data was analysed through latent content analysis, through which theme development from the interviews was applied. Interview questions were written in English but the interviewees were interviewed in the participants preferred language, which was mostly Southern Sesotho and IsiZulu. Translation from English written questions to these indigenous languages was simplified by the researcher's understanding of the language, cultural norms of the participants and elaborations were necessary. This is because the researcher avoided compromising the quality of the response, thus, this approach helped in preserving high quality in the answers provided by participants. Within 24 hours of the interview sessions, the recorded interviews were translated into English by the researcher and a transcription of each interview was created. Through the transcribed interviews, the researcher established several themes that emerged consistently. Including the following:

Officials' incapacity to facilitate community dialogue

Uncertainty about tenure security

Unaffordability of the provided services

6 STUDY FINDINGS AND DISCUSSIONS

This paper provides details of views emerging from interviews and the literature, with an emphasis on the barriers and opportunities of community participation and the impact of ineffective community participation in the UISP process.

6.1 Officials' incapacity to facilitate community dialogue

In the study conducted in Slovo Park informal settlement, ordinary community members did not seem to be actively involved in the participation process because they formed a community development forum named

Slovo Park Community Development Forum (SPCDF) to represent them. As such, the committee members consisting of a small proportion of the entire community generally consult and compile a list of the community's needs to present them at core meetings with other stakeholders. From interviews conducted with the CoJ municipal officials, it was discovered that the meaning of community dialogue as an important part of UISP process was not fully understood. The officials were not fully capacitated to handle challenges that arise when engaging a community that commonly have different opinions. This was indicated by Respondent 1 when he said "groups of political infighting whenever department conduct meaningful consultations with entire community blocks. Frivolous interruptions with planning processes especially during engagements with each and every stakeholder. Stakeholders availabilities during critical decision-making points in order to move forward with project plan. For instance, layout plan was objected against at a very late stages process after agreeing about it earlier. Earlier agreements on contents of draft layout shaped the following activities, any amendment changes entire complexion of previous agreements".

This was also admitted during an interview with Respondent 2 who is also a municipal official from CoJ. When the participant was asked to identify challenges in planning and implementing in situ upgrading, he expressed his views and indicated that "….lack of understanding of the programme by government… lack of skills and interest by government".

From what had been said, it is clear that understanding of the UISP process, particularly the aspect of community dialogue where planning process is consent was lacking. Thus, presenting a barrier for effective community participation. There were no capacitated agents from the municipality to facilitate community dialogue that will result in mutual agreements. NUSP (2015) indicated that phase 1 of UISP process thrive on meaningful community participation as these are the key stages were negotiations and decision-making occur concerning the development plans of the community. This presents a missed opportunity to understand the real needs of the end-users and open discussion to allow better understanding of government's resource limitations. This is also evident to Mathekga & Buccus (2006) argument that public officials are yet to be educated on how to facilitate community participation process. Marais & Krige (1997) argued that community participation to an effective and successful project is complicated, as such cannot be accomplished without conflicts, however, it is essential to lead to effective resource utilisation. According to Wekesa et al. (2011), it remains the officials' responsibility to educate and build capacity to enhance their participation, liaising between the community, local authority, and landowners to decide the most appropriate intervention strategy. Ziblim et al. (2013) urged that in practice, community participation is an administrative façade. Officials tend to create false expectations and subsequent disappointments in the minds of community members, who thought their views, could significantly shape decision-making in the upgrading of their settlement. This is because earlier to arranged meetings, experts would have already designed and finalised plans, thus allowing little room for community participation and influence. Ziblim et al. (2013) further indicated that public officials often avoid real participatory processes in project implementation, because they think that these are not only "time-consuming," but also, can be "unpredictable" and "messy". Unfortunetly stakeholder's unwillingness to create space for bargaining or negotiation within broad base interaction is not an attitude only seen in South Africa but in many African cities. Local authorities tend to avoid the degree of technical frameworks that comes with community consultation (Simone et al., 2005). Thus, the likelihood to implement top-down decision-making where planning and design is concerned and treating people's participation as an advisory role as indicated by Thwala (2009). However, effective community engagement and participation where ordinary community members are actively involved is necessary and can be benefiacial to both the community and the municipality. Besides it being a good practice, scholars (Burns & Heywood, 2004; Misselhorn, 2017; Moreschi et al., 2012; Pinfold, 2015 and Simone et al., 2005) observed that it has the potential to build a stronger social cohesion and solidarity, presents a privilege for stakeholders involved to gain wisdom and better understanding of the community's perspective, and develop sense of ownership amongst the beneficiaries. Most importantly, it has the prospects to achieve an everlasting collaboration between communities and government beyong the project.

6.2 Uncertainty about tenure security

Despite the confidence that eviction is no longer a threat for stand owners, it was also discovered during interviews that some residents needed more than just stand numbers and electrification to have their tenure security guaranteed. Participants indicated that despite the formalisation of the settlement and acquired land tenure security, they are unable to improve their housing structure. Respondent 3 expressed the following views "if we were to be aligned properly in a sense of sharing the plan with us where the installation of sewerage pipe will be, this would enable us to start investing in our properties in a form of building formal structures. Until then, we are compelled to stay in shacks because we don't want to risk our limited financial resources in building where we will be forced to demolish…". Another participant in the study who indicated that the settlement has been regularised and have access to basic services they previously did not have indicated that other community members have started improving their housing structure, if resources were available, she would do the same. These were expressions made by Respondent 4, who said "I have a stand number that reassures me that I will not be relocated. Even if they change these numbers every 10 years, no one can claim my stand. In the yard, I have electricity cable connected only to my house, as such, rentals are not a threat because it is clear to them too that the stand belong to me. If I had financial resources, I would build a formal structure just like some of the community members who have already started".

These are clear effects of missed opportunity for community participation during the planning phase of UISP process. Although the settlement has been formalised and land tenure security is attained, the community is unable to improve their housing structure in order to improve their overall quality of life. This is presnets a clear indication that the community was not actively involved in the layout design of this settlement. Usavaovitwong (2012) indicated that in cases where the community receiving an informal settlement upgrading programme is involved in the planning of the project, such important information is readily available. According to Arimah & Branch (2011), land tenure security should encourage beneficiaries living in informal settlements to improve their housing structure given their organisational skills and resourcefulness. However, this is not the case due to lack of crucial information pertaining the sewerage pipes sites and housing layouts. Residents anticipating housing demolition become discouraged from beginning processes of housing improvements including accumulation of financial resources because only people with good tenure security want to hold better control of their property (Nakamura, 2016). Furthermore, the omitted crucial information underpins the lack of support for Enhanced People Housing Process (PHP). Enhanced PHP policy is an important instrument for informal settlement upgrading to harness community driven initiatives to improve their top structure using own funding or social capital, but it is generally under-utilised (Misselhorn, 2017).

6.3 Affordability of the provided services

During the interviews, it was revealed that although residents have access to electricity, using it comes at a higher cost. It was indicated that most of the community members are unemployed, they do not afford to constantly top-up electricity units. As such, they often have no choice but to go back to using unsafe options for lights and cooking. Respondent 5 and Respondent 6 who were participants in this study had this to say "access to electricity improved our lives because when we could afford to buy the electricity units we are able to charge our phones but because most of us are unemployed, electricity is expensive. As such, if one could not top-up the electricity units we go back to square one, use candles and cook with paraffin stove. Therefore, access is still a problem because of our socio-economic status" Respondent 5. Respondent 6 also highlighted that government provided free electricity in the ealier stage of installation. However, when a charge was implemented it was oberved that the units cost more compared to the rural areas. These views were expressed as follow "electricity is costly and I have come to realise that the units we get are not equivalent to the units people from rural areas get for the same amount of money. We do not get government subsidy towards electricity, yet initially we had free electricity for about 3-4 months".

Without social inclusion, tenure security cannot be achieved through in situ upgrading if the UISP process does not incorporate the enhancement of socio-economies of beneficiaries by means of community empowerment and skills transfers. Based on the statements made by the above respondents, it is evident that the implementation phase of this project missed an opportunity to empower the beneficiaries so that they can be less dependent on state subsidy. According to Huchzermeyer (2006), informal settlement interventions that are not accessible to beneficiaries will result in their displacement to housing options that offer affordability and, in many cases, these are new or existing informal settlements, irrespective of the inclusiveness of the initial allocation procedure. Huchzermeyer (2008) highlighted that displacement due to unaffordability was the reason for ineffectiveness of the Kenya Slum Upgrading Programme and key

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

contributory factor was lack of meaningful community participation. According to El Menshawy et al. (2011) and NUSP (2015), meaningful community participation is crucial for the sustainability of the in situ upgrading post-implementation. Thwala (2009) observed that commonly communities are not empowered with the knowledge and understanding necessary to make informed decisions while Mathekga & Buccus (2006) also made the same observation that citizens are not well informed about participatory governance. On the other hand, local government perceives citizens as mere recipients of service delivery. This presents a barrier of meaningful community participation and empowerment in which socio-economic status of beneficiaries could be matched to the delivered services to ensure sustainability of such services.

7 CONCLUSION

The objective of this paper was to highlight the impact of ineffective community participation in the UISP process. A qualitative study was conducted using Slovo Park informal settlement as a case study. In-depth interviews were conducted with the residents of Slovo Park in order to gather views on the phenomenon. The following were the findings of the study. This paper has highlighted the lack of real community participation in the planning process of in situ upgrading implemented in Slovo Park informal settlement. This was indicated by the various community members interviewed in the study. Conflicts are unavoidable in an effective community participation because they form a crucial platform for negotiations and community buy-in into the project. However, public officials lacked capacity to handle disagreements which arised during engagements with the relevant community representatives. This implies that the final layout design of the project was not concluded with the involvement of community members. Therefore, a top-down decision was made in this regard and this was reflected on views participants in this study had regarding lack of information about where sewerage pipe sites will be. The importance of active citizenships and good participation practice was not upheld in this upgrading process, as such, it is concluded that meaningful community engagement was not achieved.

The paper reveals that some of the residents have the financial resources to build a formal top structure but due to lack of information of the plans for engineering services such as sewerage pipe, are unable to invest in their property and build adequate housing for themselves. Some households have taken the risk for potential demolition when they built formal structures subsequent to acquiring land tenure. Adequate housing influences the environmental domain of the quality of life, as such it is no surprise that some residents of Slovo Park are eager to improve their housing structure. This is also an indication that availability of information pertaining sewerage pipe sites might encourage many others. Even if the consolidation plan for Slovo Park is not PHP, given the current housing backlog, discouraging PHP approach is a missed opportunity to curb an already burdened housing backlog.

The paper also reveals that ineffective community participation has resulted in the provision of services that are inaccessible to the beneficiaries. Community dialogue could have highlighted the socio-economic status of the residents of Slovo Park and ensured that the provided services matches the needs of the community. Since most community members of Slovo Park are unemployed, UISP process should have identified that electricity is an expensive commodity that required service providers to consider community empowerment by means of skills development. Community empowerment during the implementation process is essential, especially where the socio-economies of the poor have a direct impact on the sustainability of the upgrading post-implementation. The impact of unaffordability of services will ultimately result in the displacement of beneficiaries to new or existing informal settlements where affordability is guaranteed. Moreover, the fact that at phase 3 of UISP (implementation), minimal community involvement is expected, limits the community empowerment to cheap labour, rather than skill transfers and large-scale action planning approach where the community can undertake implementation process and manage their own upgrading projects.

8 LIMITATIONS OF THE STUDY

Most of the residents of Slovo Park informal settlement do not understand the English Language fluently. As such, the researcher had to translate interview questions from English to either IsiZulu or Southern Sesotho during the interview in order to accommodate the interviewee. This limitation contributed to time consuming task of translation of all transcripts to English. Fixing of appointments with the relevant municipal officials proved to be another limitation to the study. The researcher had to postpone the interview because municipal officials were unavailable on dates or times previously arranged. Additionally, the research had limitation by methodology, as such further study can be conducted using quantitative approach with a larger sample and in other informal settlements to get a broader view of the topic.

1 ABSTRACT

The main strategic planning policy in Flanders has in view to reduce the growth of the net settlement area. It is important to enthuse people to live closer together in the centres of villages, towns or in more dense urban areas to preserve open areas. The question is how to achieve this.In the last few years, there has been a growing awareness of the importance of convincing citizens to change their behaviour voluntarily. A crucial question is which behavioural change we can expect from the population, whether this can be met at once by everyone and what a government has to change or needs to provide to make the change possible.

In recent years, the Flemish Planning Bureau for the Environment and Spatial Development commissioned several behavioural studies, conducted by Endeavour. It concerns two studies carried out on compact housing, on travel behaviour, on choice of residence in relation to facilities, and a new study on the behavioural influencers of housing. Thanks to an approach that combines the fields of architecture, urban planning, sociology and design Endeavour created a methodology of participation and co-creation with citizens, aiming at different segmentations of the population. This method successfully brought a multitude of experiences to the surface by means of a variety of people who sufficiently represent the diversity in Flanders. Insights into attitudes and motivations of a broad public are the key to understanding how to change certain aspects of behaviour into something more sustainable.

This paper focuses on two themes. The first reflects on practices, tools and knowledge that are nowadays common in (regional) spatial planning and how they relate to human behaviour. The second introduces insights from qualitative research for behavioural change that focuses on how to approach different target groups within the population. The aim is to guide behaviour in function of an inclusive and sustainable spatial transition. As the paper shows, it is important that in this transition process people do not get the feeling of 'losing' something. such as comfort or choice.

Keywords: social innovation, inclusive and sustainable spatial planning, behavioural study, participation, lifestyle

2 INTRODUCTION

The Flemish territory is characterised by large urban sprawl to which great social costs are attached (Vermeiren, Poelmans, Engelen, Loris, & Pisman, 2018). Even over the last years, an additional 6 hectares of undeveloped space is being built on daily. As a consequence open space is highly fragmented in Flanders. Regarding regional planning in Flanders, the main strategic policies have in view to reduce the growth of the net settlement area (Departement Omgeving, 2018). At the strategic level, the Flemish government has decided that the land take should decrease to 0 hectares per day and that development is best done close to facilities and public transportation.

Spatial planning policy in Flanders is mainly based on a hierarchical system. In the past decades, the Flemish government for spatial policy has evolved from a controlling government that supervises the lower government levels (e.g. in the process of granting building permits), to a government that mainly defines the strategic lines in co-creation with the same lower governments. The Flemish government still takes the overall strategic decision on spatial transition, but it gives a lot of freedom to the lower levels on how to shape this transition. However, the Flemish government has not given itself much authority to implement this decision. For many years, the Flemish government's main target group for communication on spatial planning has been municipal authorities and spatial professionals[1], whose role is actually to translate

[1] Spatial professionals are people who are professionally active with spatial policy, planning and implementation: active in governments, research, design and development.

strategic objectives into (municipal) policy and implementation. The Flemish government thus adopts a top-down approach, and does this also in order to tackle big challenges regarding sustainable spatial transitions.

In the last few years, the role of convincing citizens to change their behaviour voluntarily (e.g. by nudging) is getting more important internationally but also in Flemish policy. Examples of strategy for behavioural change in Flanders have been developed with a view to immediate behavioural change, namely to changing a habit (e.g. nutrition, waste, exercise, means of transport). Convincing people to change their behaviour is not an easy task, especially when it means breaking an ingrained habit.The accumulation of know-how on behavioural change is only at the beginning in the field of Flemish spatial planning.So far, this new target group, the citizen, is still strongly approached with the means employed by municipalities and spatial professionals. Spatial planners assume that the highly needed behavioural change is the change of housing behaviour. But, changing one's housing behaviour requires a real location move, something that most Flemish people seldom do: it is a decision that requires reflection (Slabbinck, 2017; Van Den Bergh, Aelterman, Mouton, & Engels, 2018). It requires a different approach than changing a regular behaviour.

Closing that knowledge-gab is why the Flemish Planning Bureau for the Environment and Spatial Development outsourced research to bring in knowledge from behavioural change specialists.There are several (research) questions waiting to be answered.

With these studies, the Flemish Planning Bureau for Environment and Spatial Development explores the potential and possibilities of a behavioural change strategy as a complementary strategy to the more familiar financial, rational and regulatory government initiatives. The first two studies have been completed. They provide first insights to shape such a strategy. A third study is ongoing. At this moment, the actual roll-out of such a strategy within the policy frame has not yet been decided.

3 TOP-DOWN VIEW AND BEHAVIOURAL CHANGE: PRACTICES AND TOOLS

For its regular target groups, the professionals and municipalities, the Flemish government focuses mainly on offering tools, research, information and example projects. In recent years, much spatial planning research has been done to determine the 'best' places to live near facilities and public transportation through modelling: transit node value and facility level (Verachtert et al., 2016) and walkability (Vervoort, D'Haese, Verdeyen, & Van Acker, 2019; Vlaams Instituut Gezond Leven, 2018). The used criteria are population density, diversity of facilities and average bikeable or walkable distance. Municipalities are urged to direct development to the locations with the best scores. Next to that, a lot of effort has been put into design research and good practices selection to address densification on a qualitative way, with respect of Green Blue Networks (Smets & Stevens, 2019) and healthy living environments (Atelier Romain, Osar, & P.PUL, 2020). The Flemish government also provides information about participation methods in spatial policies and implementation projects (Devisch, Huybrechts, & Stieglitz, 2017).

Various campaigns are largely built around showing possible, desirable futures, based on overall policy goals, modelling (e.g. transit node value and facility level) or design. These futures are suitable for the spatial professional and appeal to rational reflection. Three examples of campaigns launched by different parts of the Flemish government illustrate this. The first is a four-year commitment of the former Flemish Government Architect Leo Van Broeck (2017-2020) to preach in the media the often-repeated message: "denser and more compact housing protects open space". He illustrated this statement by designs or picture of –for Flanders– rather dense development with appartements. The second is an online awareness-raising survey (for the campaign "At home in the future? Do the housing test") (Vlaamse overheid, 2020). After completing questions about housing preferences, the respondent gets a picture that corresponds to its answers. This image differed greatly from the existing situation in most parts of Flanders. The third is the Mobiscore(Van Den Bergh et al., 2018), an online tool to determine whether a housing location is 'sustainable' in terms of nearness to facilities and public transport. The tool gives the users a few possibilities to include their own behaviour in the score.

While the intentions are good, offering a picture of a possible and better future and giving scores to an actual spatial situation seem to strike a nerve. When the campaigns were picked up by the media, they evoked a lot of public resistance. It led to a polarised debate between urban and rural residents, older and younger generations and progressives and conservatives, good and bad. From a behavioural standpoint, people's frustrations are not surprising: a housing choice is one that people seldom make, and can even be a choice they do not have. For many, it is a behaviour they cannot change easily.

All this recent attention to personal behavioural changes, raises some ethical questions within the Flemish planning community too. To what extend should citizens take the responsibility for systemic transitions? Van Eenoo argues that people do not always have the free choice to live somewhere or to use a certain means of transportation and that 'Urban Sprawl' is not just the result of a sum of individual –wrong– choices (De Maeyer et al., 2021; Van Eenoo, 2020). The 'ill-considered use of space' is according to several policy document analyses and expert opinions (from different fields, such as spatial planning, mobility,…) in significant part due regulatory instruments, built environment and financial mechanisms (Ryckewaert, Van den Houte, Brusselmans, Hubeau, & Vermeir, 2018). Current legal and fiscal policies work against sustainable spatial use. Another argument against the strategy of expecting too much from citizen behavioural change is, according to Van Eeno, that people do not always act consistently and that the place of residence is not the only aspect of sustainable (residential) behaviour.

4 FRAGMENTARY KNOWLEDGE ABOUT BEHAVIOUR IN AND PERCEPTION OF THE LIVING ENVIRONMENTAT THE START OF THE RESEARCH APPROACH

These discussions triggered the Flemish Planning Bureau to commission a first behavioural study: "The Experience study about compact living" (De Maeyer, Deprez, Cherroud, & Bambust, 2020). The aim was to call in external behavioural expertise. The literature section examines existing research on moving and residential motives in Flanders through the lens of behavioural insights. Besides a lot of images of possible physical forms, people have to experience it, to make that experience their own, so it becomes a lived story. For this, they not only need to see 'the' future and its imagined or calculated benefits, but also the path to and the connection with their own future, with empathy and guidance for the sometimes difficult decisions that need to be made along that path. To this end, the 7E/12E model for behavioural change (Bambust&Vanhove, 2015) is used as a theoretical framework and supplemented with theory on constructing narratives and using frames. A crucial question is which behavioural change we expect from the population, whether this can be met at once by everyone and what the government has to change or needs to provide to make it possible.

The literature reveals that there is some knowledge about the importance of life stages and housing career. Behaviour can be very different over time. So a lot of young adults are attracted to the range of aspects that are part of city living (e.g. cultural and social events). There is a lot of research showing that households with (a desire for) children move to a more suburban environment. Housing preference research also shows that a majority of the population prefers less compact forms of housing. Little attention is paid to the results of those who express a different housing preference and/or live in a different type of housing. This leads to the dominant discourse of "Mr./Mrs. Average" who think of a house with a garden in the more 'child-friendly' suburban periphery as the most ideal place to live. There is also research that shows that Flemish people are not inclined to move once they are settled. As a result, the focus of research and policy efforts on housing is often (one-sidedly) on young people and young adults for whom an alternative to the suburban home is sought.

Subsequently the literature section of the second study "The Behavioural study on proximity of facilities versus travel behaviour" (De Maeyer et al., 2021) summarises the existing knowledge about the topic. It is clear that the presence of facilities, travel behaviour and place of residence choice are interrelated. The higher the density, the closer the possible destinations are to each other and the more opportunities people have, the easier it is to choose a sustainable means of transport. Although the spatial condition plays a role in people's choices, it will not automatically lead to sustainable behaviour. Reality is much more complex.

In spatial planning and mobility practice in Flanders the effect of the built environment (occurrence and distribution, density, distance) (Van Den Bergh et al., 2018; Van Meeteren, Boussauw, De Kool, & Ronse, 2013; Verachtert et al., 2016), socio-economic and demographic factors (gender, age, family composition, education level, wealth, income …), and car ownership –nowadays still encouraged in Flanders by company and salary cars– are widely accepted determinants of that complex reality. Whether or not people own a car and/or are attached to its use influences their choice of where to live in favour of residential areas that are easily accessible by car and where parking is easy and inexpensive. In literature this is referred to as the concept of 'residential self-selection': people select a residential environment where they can best get around by the mode of transportation they prefer. However, existing data on all these relationships are rather scarce in Flanders. Some data hardly exist (e.g. frequency of visitors to facilities), others are not available on a relevant spatial scale for reasons of privacy.

The literature review in both researches reveals that collecting data on spatial behaviour in relation to those psychosocial factors is still in its infancy. Qualitative experience research is an interesting method to gain more insight into these relationships. The behavioural studies on compact housing and facilities are intended to contribute to this knowledge.

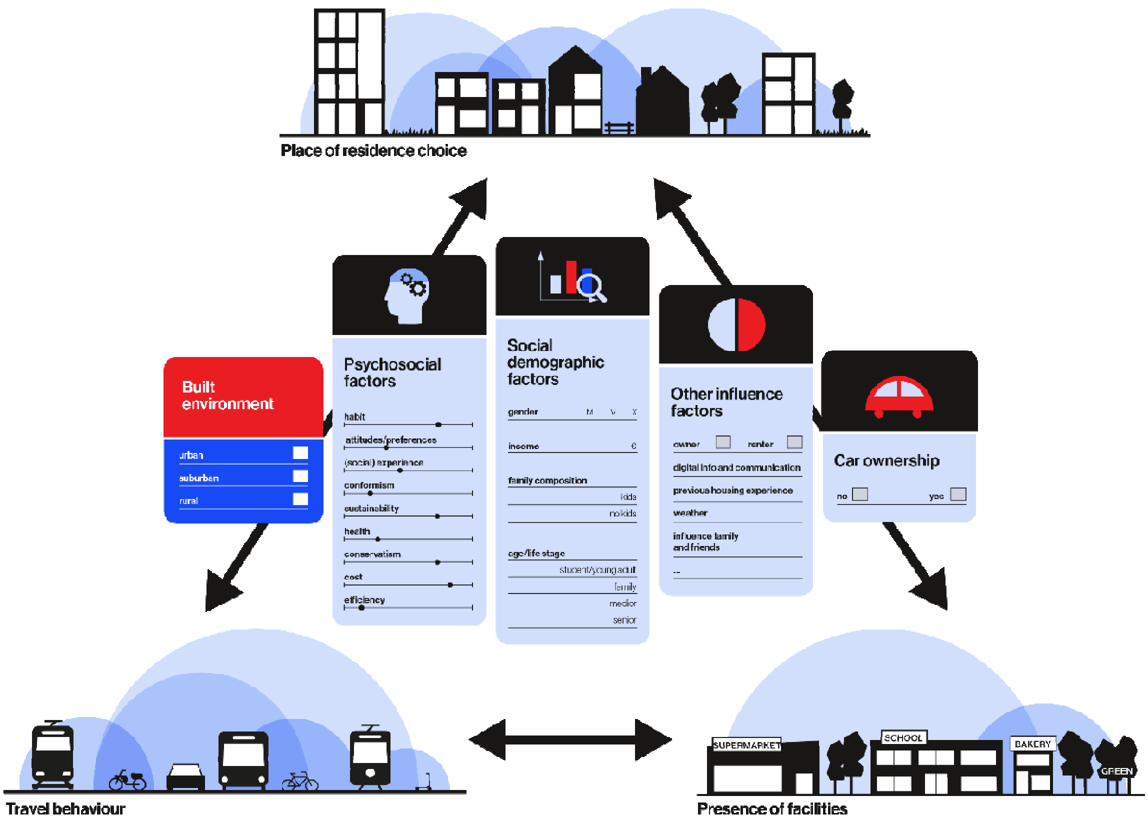

Figure 1: Summary of the different factors that influence people in their travel behaviour and housing choice

5 QUALITATIVE EXPERIENCE RESEARCH

Qualitative experience research is a bottom-up technique used to analyse knowledge of behaviour with the aim of integrating it into top-down planning policies for sustainable spatial transitions. In recent decades, participation has become inevitable in urban transitions in Flanders as people demand it more and more. While traditional public participation takes place through a public enquiry when the government has provisionally decided on a plan, the current trend is to consult those affected before the provisional decision is taken. In this way, the diversity of experiences and opinions of people participating in the pathway can help in customising decision-making. For more generic measures, instruments and policies in spatial planning that affect spatial transitions, the use of public participation is still less developed. By using interviewing techniques integrated into playful workshopsaimed at an audience that is as representative as possible of the population, the research attempts to transcend social desirability and reveal people's real preferences. In both studies, qualitative experience research was used through different methods.

The first study on housing aimed to understand the positive experience of compact housingbetter. Workshops were organised with local residents living in different typologies in five different compact neighbourhoods in Flanders and their experiences were translated into narratives and images of desirable living environments. A next round of workshops tested the appreciation of these narratives to a public living in spacious and sprawled areas and tried to understand how behavioural change could be implemented through storytelling.

Thetranslation ofqualitative data into useful communication and narratives are important. People have different values that can conflict with each other. Our choices do not always conform to the particular values we pretend to uphold (which is called 'cognitive dissonance'). That is why we want to legitimise our choicesboth to others and to ourselves. Narratives are used for this purpose. If people need narratives to legitimise or validate their behaviour, they can be helped by providing (existing or new) narratives. For people who act against the values of their peers or against their internalised values, cognitive dissonance can be anticipated and the likelihood of intrinsic motivation increased. This can be done by framing the behaviour within the Values, Themes, and Concrete situations ('VTC framing') of the target group. For individuals where the values are already aligned with positive behaviour, stories can be offered as reinforcement as a means of self-telling. This framing cannot be just fiction, but needs to be built on true experiences to be successful, so that new choices must also fulfil the promises told in these stories.

For the second study qualitative experience research was used in two rounds. In the first round, as much personal information as possible was collected about past and planned residential choices, regularly used facilities and services, and the movements to these facilities. In between, we drew up hypotheses for psychosocial segmentation in the behaviour of citizens. In the second round, these hypotheses were tested, as was the willingness to undertake personal actions related to goals of Flemish policy. When testing actions and policies, this qualitative experience research comes close to the principles of a deliberative democracy (Bessette, 1981) and experiments with citizens panels like the G1000 that took place in Belgium and the Netherlands over the past decade.

6 A ROADMAP FOR SPATIAL TRANSITION

The research of the behavioural series has already envisioned that the transition needs both governance, including policy action and citizens behavioural change, but also the collaboration of shapers of our environment and society (De Maeyer et al., 2020, p. 93). In the first study, 'handles for behavioural change towards compact living' were elaborated in which both are linked to each other. One type of recommendations concerned communication and policy. Other recommendations were addressed to local authorities and spatial professionals who stressed the importance of qualitive neighbourhood- and housing developments from a user perspective. The study also formulated a working method based on psycho-social insightssuggesting to translate the strategic vision of the Flanders Spatial Policy Plan into Roadmap, a (operational) work plan supported by a motivation plan(De Maeyer et al., 2020, p. 89). The work plan is equivalent to an approach in terms of governance, the work that the government itself has to take up, changing laws, rules, mechanisms, etc. The motivational plan is necessary to keep (especially) citizens on board. The roadmap consists of 10 phases and going through them will take years.

The experts in behavioural change confirmed that the polarised debate and current campaigns will not be sufficient to get enough people on board to make the necessary transition. In the current phase of policy making, it is too early to show images, or to give people the feeling that they are not compliant. It is time to wait until the government has decided about what is necessary and acts accordingly, so that change is actually possible or easier, and that the first initiators have gained experience.

In the current phase of policy-making about the transition (first and second phase), De Maeyer et al. (2020, p. 94) advises to work with prognostic and motivational frames: asking for help with ideas of what the future may look like. This could be a higher-bar approach: accepting the challenge and even raising the bar. Or an additional approach that counters fear of loss, identity, quality of life and therefore emphasises that multiple interpretations will be possible. In these frames, the emphasis is much more on preserving and strengthening residential quality than on higher density. Maybe it is interesting to show what people (the next generations) will lose without transition. In motivational frames, people are not framed as co-problem owners, but as solution selectors.

7 GETTING STARTED WITH PEOPLE WHO HAVE TO CHOOSE ANYWAY

Since a transition towards a more sustainable choice of transportation and of housingfor a large part of the population can only take place step by step, it would be rather counterproductive to mobilise everyone at once. The roadmap takes into account that the spatial conditions are not yet ready for a rapid transition. Pilot projects for resettlement and reorganisation of mobility to more desirable spatial conditions are already being implemented and will be scaled up step by step. Regarding Roger's adaptive model (Rogers, 2003), Innovators and Early Adapters are needed to mobilise a broader population in time, meaning the early and late majority and laggards. In addition, the behavioural studies have taught that not every innovative or desirable product (in this case, a house or a mode of transportation) will be equally attractive to different segments of the population. Behavioural theory additionally teaches us that behaviour is usually consistent.

Breaking moments can trigger new behaviour. Preference for a new home and housing type is strongly influenced by life stage, which often goes hand in hand with age. Life stage factors such as graduation, starting work, moving in together or getting married, having children, etc. are often the cause of a move (De Bruyne&Iserbyt, 2011).

The "Experience study about compact living" discusses a socio-demographic segmentation not just by life stage (which is a frequently used method in literature) but via four important breaking moments that give rise to choosing a new home, often in relation to a specific target group. For each of these target groups, narratives were constructed. The first group is looking for independence. This usually involves young adults leaving their parents or adults dealing with a relationship breakup. The second group is looking for more space. This group consists mainly of young and new families who are expanding. A third group is looking for community and free time. This group of people is faced with more free time as children grow up or one retires while still living in spacious single-family homes and social life again takes more place outside. The last group is looking for security and accessibility to health care. This group usually consists of the elderly and those in need of care. Generally less drastic are the breaking moments that can cause a change in travel behaviour. A new job or having children are often triggers though that can influence this behaviour (e.g. picking up the children on the way to work). But apart from that, a choice of transport mode is a result of a complex system of factors that acts on the choice process. Acting on behavioural change, big choices like a new house are therefore important moments to nudge or inform people. To gain more insight in the key-factors that determine the decision making regarding housing, the new research that just started will collect more knowledge. Regarding the change of transportation habits, insights in breaking moments will be crucial as this type of decisionmaking is less drastic and easier to implement.

8 THE AVERAGE PERSON DOES NOT EXIST: ABOUT SEGMENTS AND MOTIVATIONS

If the Flemish government wants to encourage citizens to behave in a more sustainable way, it has to know what actions it must or can take with respect to certain segments of society. Not everyone acts for the same reasons or encounters the same barriers. What is an obstacle for one person is a motivation for another to live in smaller space or to change his/her mode of transportation. By taking into account the diversity of persons and better connecting to the living and mobility behaviour of the Flemish people, measures can be used more efficiently to stimulate certain choices. A better understanding of behaviour can therefore be an important factor in a spatial transition in Flanders.

Whereas with a socio-demographic segmentation, it is already known and broadly accepted, which persons should be addressed to make behavioural changes possible (e.g. young adults), it is much more difficult from a psychosocial point of view. Merely targeting behavioural change according to a socio-demographic segmentation would not be sufficient to capture the complexity of choices. An extensive segmentation based on psychosocial factors makes it possible to also focus on changing the behaviour of persons on the basis of their underlying motivation (whether or not unconsciously) that plays a role in making choices. In the second study a psychosocial segmentation three types of motivation are discussed that can lead to behavioural change, in relation to some specific target groups: socially motivated people, intrinsically motivated people and extrinsically motivated people.

By allowing policy measures to respond to these motivations, the framework through which people look at the world can be adjusted in order to establish new consistent behaviour. This is also called frame bridging. These measures are particularly important for intrusive questions such as finding a home or determining a lifestyle, but accompanying circumstances can also have a major influence. Behavioural studies conducted in recent decades have shown that these accompanying circumstances, which cannot be traced back to any of the above motivations, are more important than previously estimated. People do not always get around to testing the dilemmas or the possibilities against their value hierarchies, even when making important choices, because getting to the bottom of all the effects of choices takes a lot of energy and time. It requires a form of ‚meta-intrinsic motivation‘ to give priority to this. People prefer to be led by the path of least resistance. Thus, nudges do not interfere with motivational measures, but help them.

9 AN INITIAL PSYCHOSOCIAL SEGMENTATION FOR CHANGE OF RESIDENTIAL BEHAVIOUR AND USE OF FACILITIES

The behavioural studies not only allowed us to paint a more complete picture of a complex reality, it also gained us more insight into the relations between different factors for different people. The barriers experienced by the various persons were noted as well as the levers for making more sustainable choices. Because positive perception is an important lever for future behaviour, the focus is primarily on the motivations behind those choices, as social, emotional and cultural motivators can ultimately determine or impede someone‘s choice. The analysis of psychosocial factors led to very different groups of people motivated according to different categories; namely intrinsic, extrinsic and/or social motivation. Of course, special attention still needs to be paid to the various breaking moments in a person’s life.

First of all, it is important to recognise a group of people that is not yet motivated for the time being. This group may eventually find its way within other motivations but it is not easily persuaded to change its habits. We can find this attitude in Rogers' late adopters. Similarities can be found with a group of people that is more conservative, but can be guided by intrinsic motivation. The living environment where these persons grew up is often a crucial factor in the choice of a place to live. The home is preferably located near friends and/or family and in a quiet area with its own garden, where one feels secure. These people attach importance to traditions and conventions in which they are embedded and often see these as part of their identity. This behaviour is also often expressed when moving to facilities, usually using the most familiar mode of transportation, interwoven with their identity, even though it may not be the most efficient way. They prefer to go to already known facilities: "I feel comfortable in stores that I know and where I automatically know the layout. The same store can look totally different in another town, which makes me feel a slight panic". Because these people often show resistance towards what they can lose, it is important to frame (ENLIGHTEN) what they also lose within the non-engagement of the strategic objectives. The levers for choosing where to live and sustainable travel behaviour are therefore best explored within the 'Nudging area' as well as within motivation: we want to bring about a disruption within the identity of this target group and immediately present an alternative, consistent story. An example of this is making it impossible to drive your car up to the school gate (ENFORCE) while telling people that they will be fine with this because they are concerned about the safety of their children (ENTHUSE).

Besides that also other intrinsic motivations can be decisive in determining one's behaviour. People who value sustainability for example are concerned about the ecological and social consequences of their behaviour. In many everyday actions they make critical choices in favour of the environment in terms of mobility, type of (online) facilities but also place of residence. For another (and often partly overlapping) group, health is the most decisive factor. For this group, the (proximity of) a green and healthy residential environment is often a determining factor in the choice of a place to live. In terms of the home, criteria such as peace and quiet, air quality, availability of a (collective) garden and/or the proximity of green spaces therefore play a role. Health is also a factor in the choice of certain facilities and more effort will be made, for example to purchase organic products. This behaviour continues when moving to facilities where active modes of transport such as cycling are consciously and consistently chosen: "I really enjoy cycling immensely, because it's pure relaxation. It's a lifestyle which I also carry through into everyday life". These individuals are best persuaded by designing healthy urban living environments with proximity to facilities (ENABLE). The lack of this today often prompts them to choose more peripheral locations. With good and safe bicycle infrastructure (ENABLE), they are often willing to travel sustainably and cover long distances anyway. Mapping sustainable mobility options or technology to make goals measurable can help them do so (ENLIGHTEN).

Social motivations also determine location choice as well as travel behaviour. We distinguish two social motivations that differ greatly in their spatial behaviour today. The first group to which social motivation is important is that to which experience is the core of the behaviour. For this group, travel behaviour is often socially determined. Running into people, the chance to have a chat, discovering something new, etc are important to them: "We love cafés and restaurants, which is why we wanted to live in the city. We also like to walk because on the way we always meet someone we know.“ They are therefore more likely to use active forms of travel and public transport and are more likely to live in city and village centres. With this group, it is important to capitalise on that experience and also to highlight expectation (ENLIGHTEN).

The fact that today in Flanders a majority does not live in village centres or urban areas means that people who are easily influenced by others, have limited reason to make that choice.This second group are people who seem to strongly conform with their peergroup and it contains persons who are strongly group oriented and who consciously or unconsciously allow themselves to be influenced („FOMO“) by the opinions and/or choices of their peers with regard to choice of transport mode, type of (online) facilities and choice of place to live. Behavioural changes occur in the context of the peer group and in imitation of role models, influencers and opinion leaders. If picked up by the "right people" they may be able to be steered. The timing of moving this group is important here: they may be difficult to address as a first sub-target group, but often come up in a second or even third phase, when we can show that 'others like you' are doing it too, an attitude that we find especially in Rogers’ early and late majority.

In addition to social motivation, extrinsic motivations also play an important role for certain people. For example, cost is for many the most decisive factor in making choices. Cost plays a role in the choice of a home and place of residence but for some can also be quickly seen as an investment rather than "a home". It offers better value for money, so it is worth looking at the total cost (energy and travel costs, location, subsidies, etc.). For this group of people, this behaviour is also seen for movements to facilities, where cost savings usually take preference over comfort or time: "I regularly use 'Toogoodtogo' because it is cheaper. However, there is not so much choice in my own neighbourhood so I drive further for this. 15 km is the maximum though because otherwise it is no longer profitable." They seem to be late rather than early majority (unless there are economic triggers), and sometimes laggards - with a relatively low degree of reflection on their own behaviour patterns. This segment is most susceptible to extrinsic motivation linked to financial incentives (ENCOURAGE) such as a bicycle allowance. In addition, their behaviour can be steered by informing them about the financial benefits of desired behaviour or also by helping them visualise future profits (ENLIGHTEN).

For another group however, efficiency is the most crucial factor. The location of the residential environment is therefore often important in choosing a place to live so that family and work life can be organised well. The home is preferably located near an easily accessible centre with different facilities and work. 'Efficiency above all else' is their motto. This behaviour also sets in when moving to facilities where the easiest and fastest (or combination of) mode(s) of transportation is always chosen. These persons will also take other factors into account (travel time 'from door to door', parking space, infrastructure, ...) and often visit linked facilities so that time loss can be avoided. 'Win-win situations' such as exercising or working during a commute are nicely taken into account to make good use of their precious time: "I always try to look at where I need to go and how I can combine it so I can do it as efficiently as possible." This group is most sensitive to extrinsic motivation linked to time savings/convenience (ENCOURAGE) and, in addition, can be steered in its behaviour by informing it on the benefits of desired behaviour through data (ENLIGHTEN). Flexibility of the car pushes many in this group today towards unsustainable travel behaviour. Public transport is often impractical, the bicycle too slow and alternative sharing systems still too limited. By removing these barriers, the desired behaviour can be more easily achieved than the undesired behaviour (ENABLE). Efficiency often goes hand in hand with comfort, for example by making public transport sufficiently high quality (e.g. Wi-Fi) so that time can be used usefully but also by making car facilities (e.g. parking) less accessible. At certain breaking points, such as having children, this group is being 'pushed' into being efficient. At such a breaking point, it is important to be able to offer solutions quickly. Change causes discomfort and stress, which often causes people to hold on even more to what they do have. The panic button –named for the user's underlying sense of panic– then ensures that we not only unburden them by offering other solutions in this one area but also help them to integrate those solutions into their lives. Therefore it is advisable not to propose one single solution (the bicycle) but also multiple ones (car sharing, bus, car...) in search of what better suits them (ENTHUSE) and their social middle and status (ENGAGE).

10 CONCLUSION

Aspatial transition needs abehavioural change.This is a process that takes time and the ambitions must growstep by step, together with the group of people that is able and motivated to step into that process. To help politicians with this complex task we suggest the creation of a detailed roadmap for sustainable spatial transition. It contains a systemic approach in which a (operational) work plan is supported by a motivation plan. Every step within the plan has to be well defined and measured. To reach the next step the goals of the previous have to be reached. We suggest an extension to the roadmap presented in the perception research of ‘compact living’.At the same time it should also contain at least aspects regarding mobility and the provision of facilities and services. This roadmap should take into accountthe following advice:

(1) Which behavioural change by whom?

Which behaviour people need to change remains a complex question to answer, and relates to the wishes and situation of each individual. In today's reality, there are many people who have no immediate role to play in reducing urban sprawl, e.g. because they live in a city or village centre or in a home that is adapted to the size of their household. Other people(still) live alone or with their partner in a house that is suitable for a family. In their case, the behavioural change could be to move to a smaller house. Other people dream of moving to a newly built, open house in a non-urban environment. The behavioural change for them could be to buy an existing house instead of a greenfield. Situations differ among people and psycho-social factors also do. How to address the right people at the right time and facilitate desired behavioural change in an appropriate way is not yet clear in the current state of research. It will be addressed in further researchin order to feed policy.

(2) The choice of place of residence and mode of transport are two behaviours that are intertwined and ask for an integrated strategy

The concept of residential self-selection teaches us the intertwining of two behaviours. Understanding that the choice of a home is a long-term issue and is made less frequently than that of a mode of transportation means that we can assume that efforts to achieve more sustainable mobility behaviour will lead to more desirable spatial organisation in the long run. A focus on the accessibility of facilities and services can work complementarily to this approach to enable more sustainable choices.

(3) Positive experiences are key

Recent efforts to encourage people to cycle to work or use co-mobility (car or bicycle combined with public transport) may, through positive experiences, increase the general appreciation for sustainable modes of transport. Positive experiences can then influence the long-term choice of where to live. We need to emphasise "positive" in positive experiences. Bad experiences are detrimental to a sustainable transition. While today electric bikes are widely promoted, qualitative perception research taught us that many perceive it as too dangerous given a lack of safe or adequate bike infrastructure. Bad experiences with overcrowded and delayed public transport would also have that effect. The perception research also confirmed that quality control of new development is important in order to compete with the successful suburban alternative. Non-quality densification can even create resistance to desirable spatial transitions.

(4) Political courage is needed to create a financial shift

How does a strategy on voluntary behavioural change fit into the overall policy to bring about the transition? Behavioural science clearly shows that the government cannot expect a change in behaviour if there are great difficulties to overcome for the desired behaviour.Policy will have to remove the obstacles to make the demand for behaviour change credible. A financial shift will be crucial to create a multi-shift in our behaviour towards mobility and housing. If transport-oriented development is to be encouraged, the capacity, frequency and network of public transport and cycling infrastructure must also be significantly expanded and desirable housing conditions will need to be affordable. Next to that, financial incentives for unsustainable behaviour will have to be phased out while nudges for sustainable behaviour will need to increase. That means an overall consistent policy from different fields: all legal and fiscal policies (mobility, housing, salary cars, …) must work together to achieve a sustainable spatial use. A good deal of political courage will therefore be needed to implement changes that could provoke resistance, not least because these decisions will limit some acquired privileges of a broad population.

(5) Diversity in the modes of participation in the transition is needed

To convince politicians to make such drastic changes, a significant part of the population must already be convinced. Therefore it must be possible for everyone to be able to become part of this transition process. Contributing to sustainability sometimes risks being a story of the privileged creating aversion among a broader group. Therefore every small contribution counts and can be a stepping stone for a larger transition over time. By gaining good insights into the values, themes and concrete situations of different segmentations in the population, policies can work in a more targeted way and offer everyone opportunities to get motivated and contribute to the change. Therefore, pilot projects should not always seek the extremes, but also find common ground for everyday people. Within different segments it is also important to focus on all ages. A focus on different breaking points in people's lives will initiate a broad transition over time.

(6) Communicate empathetically

Accusing people of making the wrong decisions works counterproductively.Not everyone will or can be motivated to change his/her behaviour at an early stage of the transition process (cf. Rogers). Judging behaviours of the late majority and laggards will encourage demotivation and a sense of loss.It is better to give people opportunities and support to change aspects that they themselves can control and to communicate with them empathetically at the right times. It is important to understand that change can be difficult for certain groups of people: policies and context must help people understand that they do not lose but win something.

1 ABSTRACT

City resilience has gained increased recognition due to the COVID-19 pandemic situation and thus the topic has become one of great research interest, with several research projects focusing on city resilience within the last few years. However, in order for the project results to have an impact, meaningful stakeholder involvement needs to be centered. Acknowledgement of this need has lead to the use of different approaches in research, such as the use of co-creation activities and standardization, which aim to integrate city resilience stakeholders in the development processes of different tools and methods. This paper assesses the approaches of two city resilience-related research projects (Smart Mature Resilience or 'SMR,' and Climate Resilient Cities and Infrastructures or 'RESIN') and suggests an enhanced approach for combining co-creation and standardization – in a model called a Mutual Learning Framework – that is being used in an ongoing project called Advancing Resilience of Historic Areas Against Climate-related and Other Hazards, or 'ARCH.' The outcomes of this research will support the development of robust stakeholder engagement within city resilience, particularly in tool development and validation processes; ensured by a mix of co-creation and standardization methods.

Keywords: stakeholder engagement, city resilience, standardization, co-creation, research projects

2 INTRODUCTION

The topic of resilient cities is not new (Rockefeller Foundation and ARUP, 2014). However, the COVID-19 pandemic has put city resilience in the spotlight, more than ever (e.g. McCartney et al., 2021). This applies also for all city stakeholders and especially citizens, who also see the urgency of (climate) resilience. But involving all relevant stakeholders in research activities for the development of resilience-enhancing tools has not been simple thus far. The European Commission identified this issue a few years ago and requires the integration of research relevant stakeholders and end-users in the dissemination and exploitation of research projects: As noted by the Commission, intended audiences of research and tool development often includes groups such as city representatives (European Commission, 2015). One approach to bridge this gap, proposed by the European Commission within European Framework Programmes (FP) such as Horizon 2020 and Horizon Europe, is the tool of standardization, which can be used to actively support the exploitation and dissemination of FP projects (European Union, 2013; European Commission, 2018).

However, when reviewing FP projects, dissemination and exploitation activities during the implementation phase remain shallow and seldom reach affected stakeholders in a meaningful or actionable way. Only a few research projects have made specific progress on this topic and successfully integrated relevant stakeholders to enhance city resilience tools. The integration of cities within FP projects is key if the goal is to involve relevant stakeholders in achieving the common goal of becoming resilient cities in the future. This is primarily because a city cannot be resilient without the resilience of its critical infrastructures, citizens and network of cities to which it is connected in various ways. However, successfully involving the stakeholders and cities into projects depends very much on the approaches chosen, and depends heavily on the ways used to bring the theory of research into practical future uptake by cities. Different approaches are available, such as co-creation or standardization, but these approaches remain under-examined.

Therefore, the aim of this paper is to propose an approach for combining the methods of standardization and co-creation in research projects. To achieve this, the two EU-H2020 projects SMR 'Smart Mature Resilience' and RESIN 'Climate Resilient Cities and Infrastructures' on city resilience were assessed, with special focus on the success and impact of co-creation and standardization activities. The results of this assessment are used within the EU-H2020 project ARCH 'Advancing Resilience of Historic Areas Against

Climate-related and Other Hazards' to develop a methodology for enhanced stakeholder engagement by co-creation and standardization.

The aim of ARCH is to make areas of cultural and historic value more resilient against climate-related and natural hazards and risks (ARCH, 2021). To this end, the ARCH team will develop a suite of tools to: (1) collect existing and new information about hazards and vulnerabilities; (2) assess risks and resilience of historic areas under different scenarios; and (3) identify effective pathways and action plans to increase resilience. These solutions are developed using a co-creation method combining mutual learning activities, co-creation workshops and standardization activities. The city-focused project includes partners from the cities of Bratislava, Camerino, Hamburg and Valencia, who will co-create project tools in efforts of helping their respective cities and others to protect their historic areas from the effects of climate change. From the outset of the project, the co-creation method included different principles such as equality, openness, transparency, flexibility, inclusiveness and reflexive/iterative learning, as well as trust, accountability and credibility (ARCH, 2020). Based on the co-creation activity, a Mutual Learning Framework has been set up to foster direct knowledge exchange and experiences among the partners of the four initial project cities, which are also called the Foundation Cities, and a larger group of European cities called the Keystone Cities who aim to increase the resilience of their historical areas.

The paper is structured as follows: the topic of city resilience is further introduced and some approaches for using co-creation and standardization are presented in Section 2. Section 3 describes the methodology used for this research, and Section 4 includes the results of the assessment of the two projects to support the methodology used in the ARCH project. Finally, Section 5 summarizes the research and provides an outlook for further research.

3 CITY RESILIENCE WITH SUPPORT OF CO-CREATION & STANDARDIZATION

Research done in EU-funded projects has intensified over the last decade and has shown that while negative impacts of climate-related hazards (such as heavy rainfall, heat waves and earthquakes) and human-induced ones (such as industrial pollution, radiation, toxic waste or transport accidents) on urban areas are widely discussed their impacts and cascading effects are not yet understood to their full extent. All of this, in addition to the layered impacts of the COVID-19 pandemic, remain a gap in our shared understanding.

In existing literature, several frameworks have been developed to describe city resilience, tools have been suggested for the enhancement of city resilience, and the importance of stakeholder engagement and interaction for city resilience has been identified (e. g. Kontokosta & Malik, 2018; Hernantes et al., 2019; Mourshed et al., 2016).

The need to transform our societies towards climate protection and sustainability has become more urgent due to climate change and the overuse of natural resources. The global COVID-19 pandemic has caused an economic crisis and made long-standing social inequalities within and between our societies more visible (e. g. Blundell et al., 2020). By working on resilience, cities may ensure that a functioning local and regional economy and a just urban society respect planetary resource boundaries, while remaining driven by solidarity and cooperation. Work on city resilience seems therefore not only urgent, but inevitable. Moreover, increased attention and efforts in the area of resilience lead to sustainable development in cities, towns and municipalities. To do this, cities need to safeguard and protect their critical infrastructure and assets (e.g. historic areas), often while simultaneously dealing with pressing chronic social and economic stresses.

To further understand and work with the topic of city resilience, a common definition is needed. Derived from the SMR project, city resilience can be defined as: the ability of a city or region to resist, absorb, adapt to and recover from acute shocks and chronic stresses to keep critical services functioning, and to monitor and learn from on-going processes through city and cross-regional collaboration, to increase adaptive abilities and strengthen preparedness by anticipating and appropriately responding to future challenges (Maraña et al., 2019).

In order to achieve city resilience, standardization is one approach for transferring outcomes of research projects into practice; especially attractive as an option because it follows a transparent and open process. In this regard, it has to be noted that standardization can be conducted twofold: The first and most common process for standardization is formal standardization within technical committees. In these committees, experts of all relevant fields are part of developing different kinds of standards for the benefit of everyone

(ISO, 2021). However, these committees address many different subjects, so not all possible relevant research and innovation activities can be easily integrated and adopted in this technical committee system. As a result, a second route has been developed for standardization deliverables, such as Workshop Agreements. This method provides an additional tool for bringing research and innovation outputs into standardization (Poustourli, 2016). On the European level, CEN Workshop Agreements (CWA) can be used for research projects (CEN, 2021). Figure 1 shows the different steps of initiating and conducting a CEN Workshop to develop a CWA.

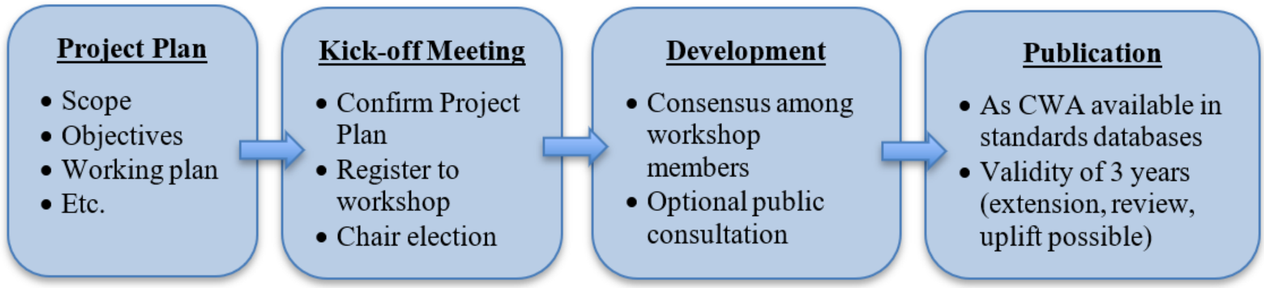

Fig. 1: Process of a CEN Workshop to establish CWAs

Due to the different process steps to develop a CWA, several possibilities to involve relevant stakeholders for the topic of the standard can be exploited and fostered. For example, as the CWA project plan is made publicly available for at least 30 days, interested stakeholders (even from outside of the project) can join and give input during the process. Also during the development phase of the CWA, relevant stakeholders can be easily and quickly integrated (CEN, 2021). However, the later that the stakeholder integration takes place, the more difficult it becomes to reach consensus among the workshop members. As standardization activities generally rely on developed tools and methods of a specific research project, the CEN Workshop process can also be used for co-creating the envisaged project outcomes.

Several references on co-creation methodologies for research and innovation projects in general, as well as on resilience exist. For example, Weichselgartner and Kasperson (2010) assessed successes and failures in collaborative knowledge production within the domain of resilience, based on 20 scientific assessments. With regard to research projects, the action research method of co-creation is of major interest. Here, the consideration of co-creation of the inputs and outputs of the research translates into practical outcomes, such as an example of a study with the public and governments (Cook et al., 2013). The benefits of participatory research approaches, in which we include co-creation, are that these bring the scientific process closer to decision-makers, enhance the perception of research outcomes and facilitate interaction among relevant stakeholders (e.g. Cvitanovic et al., 2019). Furthermore, existing literature on general co-creation activities refers to the objectives of the co-creation method itself and the influence factors and the outcomes of co-creation; whereas the discourse in this literature is limited as it relates to the eventual outcomes of the co-creation processes (Voorberg et al., 2015).

Standardization processes can adopt a co-creation approach. For example, in the practice of creating standards for city resilience, city officials and other experts come together to share their views and input in co-developing standards. Standardization around city resilience tools and processes can add to the co-creation process, as detailed input is requested from experts and stakeholders in a guided and facilitated way, where each workshop builds on the work that is done in the previous ones. This does not mean that the process is not flexible, but rather the opposite; one in which all voices have the opportunity to be heard and ideas the chance to be addressed. However, existing literature is lacking information on how co-creation and standardization activities can be combined successfully.

The presented research overcomes this gap and provides details on how both approaches can be successfully used within research projects to transfer theory to practice; and with regard to city resilience, to provide the cities with resilience-enhancing tools - ones that are especially easy to identify with, understand and adopt thanks to the fact that they co-developed them. Furthermore, as the inclusion of standardization in research projects is currently not addressed in the state of the art research, the link to standardization as a supportive tool for co-creation activities has not been well investigated. Therefore, it is important to review projects having successfully implemented standardization in the context of co-creation activities.

4 METHODOLOGY

This research was conducted by using the action research methodology. Chein et al. (1948) suggested the four dimensions of action research: diagnostic; empirical; participatory and experimental. Thus, they define participatory action research as a method in which researchers and practitioners actively participate in all stages of research. Furthermore, participatory action research has been verified as a method to make scientific findings useful for practitioners (Ottosson, 2003).

The information flow between research and practice, and vice versa, is crucial. This is especially true when it comes to achieving applicable resilience-enhancing tools for cities. Thus, this method can be a win-win relationship: firstly, for the researchers, as their tools will be directly brought into practice and be applied to the research projects assessed in this paper; and also for the practitioners, like city representatives who gain access to tools for which they provided essential input. In this way, action research has previously been used in other research projects.

In the framework of this action research, the RESIN and SMR projects have been assessed through the direct participation of the researchers in these projects. RESIN was an interdisciplinary, practice-based research project, funded under Horizon 2020, investigating climate resilience in European cities. The project was completed with direct co-creation activities involving the cities of Bratislava (Slovakia), Bilbao (Spain), Greater Manchester (United Kingdom), and Paris (France) and knowledge brokerage with 17 additional European municipalities. The project developed practical and applicable tools to support cities in designing and implementing climate adaptation strategies appropriate for their local contexts. RESIN also compared and evaluated methods that can be used to plan for climate adaptation to move towards formal standardization of adaptation strategies.

SMR was also a Horizon 2020 project, the objective of which was to develop a European Resilience Management Guideline (ERMG) consisting of a set of resilience-enhancing tools such as a Maturity Model, Resilience Information Portal and Risk Systemicity Questionnaire. These were intended to support city decision makers in developing and implementing resilience measures. Therefore, the project used a co-creation method to involve further cities and stakeholders. Furthermore, SMR implemented within the co-creation process their tool development, validation and, finally, approval by city councils. In order to ensure the usefulness and reliability of the results, the SMR project involved the cities of Bristol (United Kingdom), Glasgow (United Kingdom), Kristiansand (Norway), Riga (Latvia), Rome (Italy), Donostia-San Sebastian (Spain) and Vejle (Denmark) in the project consortium and adopting a co-creation approach throughout the project to foster the integration of project-external cities in the tool development, verification and future application.

The lessons learned during the course of the co-creation and standardization activities conducted in these two projects have been gathered in this paper, setting a specific focus on the stakeholder involvement and the impact the conducted activities provided. The results of this assessment are being implemented, reflected upon and further enhanced in the ARCH project to successfully combine standardization and co-creation activities. Thus, the findings lead to the development of an improved approach in ARCH. The outcomes of this research will support the development of robust stakeholder engagement within tool development and validation processes, as ensured by a mix of a co-creation and standardization approach.

5 COMPARISON AND DISCUSSION OF COMBINED CO-CREATION AND STANDARDIZATION APPROACHES

This paper analyzes RESIN and SMR projects separately and provides information on how the standardization and co-creation activities were conducted. The lessons learned in these assessments are integrated in a comparison table. Table 1 outlines the general setup of each project, as related to co-creation and standardization, as well as post-project reflections on success factors, challenges and impacts.

5.1 RESIN project

Generally, the RESIN project employed multiple co-creation approaches tailored to the individuals and organizations involved in different tasks. This resulted in variations in conducted activities, timing of activities and depth of co-creation. Initially (i.e. during project design), RESIN planned a more traditional development process, with finite and separate stages for development, testing and user feedback, where each stage would conclude in the 'handover' of a formal report containing relevant results. Separate stages were envisaged to be guided by close cooperation between technical partners and city partners. However, shortly after the start of the project in November 2015 this approach shifted to focus more on the co-creation of knowledge due to the needs of the city partners and advice from the project's external scientific advisory board. The aim was to align development activities even more closely with the ongoing issues at the local level in the partner cities. Subsequently, the more traditional development process shifted to a more agile process with more frequent and iterative testing and feedback loops between the technical partners and city partners.

The project design (prior to the shift mentioned above) envisaged that city partners' engagement with research partners in the development of tools would be guided through different activities, including: Process Management Workshops to foster an understanding for resilience building; development of a 'City assessment report' to communicate the state of local adaptation work in each city; and bi-monthly webinars between cities and tool developers to provide regular progress reports to one another. Additionally, different workshops, stakeholder dialogues and webinars were conducted in RESIN to integrate additional city practitioners into the project and to support co-creation of the resilience tools (RESIN, 2018a). Thus, the above activities provided a framework for co-creation of the tools. The co-creation processes between tool developers and city partners differed between the three different solutions developed by RESIN and based on the resources available in the cities. For example, while full risk analyses using the new method developed in RESIN were conducted with the cities of Bilbao and Bratislava, only a qualitative assessment was conducted for Greater Manchester, while the city of Paris followed the development processes more loosely. While standardization was originally envisaged as a cross-cutting exercise spanning all city cases, it was not consistently implemented in all the co-creation activities with city partners. Instead, standardization was often pursued from the viewpoint of technical partners developing tools and methods, with city partners being consulted infrequently (see RESIN, 2018a; RESIN, 2018b). For example:

- A survey on city viewpoints on standardization was conducted
- City partners were involved if dedicated standardization sessions were conducted during bi-annual project meetings

Instead, individual partners pursued standardization activities on international, European, and national levels (e.g. via memberships in ISO / CEN / national committees and working groups). An originally foreseen CEN Workshop Agreement was not pursued. Instead, RESIN produced recommendations for future standardization activities, based on the final project results (RESIN, 2018b).

5.2 SMR project

The co-creation approach used in the SMR project ensured the active involvement and engagement of stakeholders in the production of knowledge. This included experts from local, regional and national governments, academic and scientific entities, and public and private companies. Several methodologies such as workshops, surveys, the Delphi method and semi-structured interviews were used to foster co-creation in the development of the five tools that support the ERMG. The standardization of the tools and ERMG was also undertaken as a co-creation process in a transversal way throughout the project. In fact, the standardization activities were envisaged from the very beginning, integrating sessions dedicated to standardization in the co-creation workshops for the development of tools. Once the tools and ERMG were developed, the SMR partners assessed the standardization potential of each solution, which resulted in the development of the CWA 17300 series on 'City Resilience Development' regarding the ERMG, Maturity Model and Information Portal (SMR, 2021). The development of these CWAs enabled further input from other project external stakeholders such as representatives from other cities or other resilience-focused research projects.

The SMR project defined a Circle of Sharing and Learning for the involvement of, and dissemination to cities. The three Tier 1 cities (Glasgow, Kristiansand and Donostia) were the earliest adopters, which implemented the ERMG and served as a testing ground for the pilot tools. Tier 2 included the other four partner cities (Riga, Bristol, Rome and Vejle), which acted as peer reviewers in the pilot implementations, providing advice. Tier 3 included the cities already considered active with regard to resilience, e.g. those who participate in the UNDRR resilient cities campaign or have been selected to participate in the 100

Resilient Cities of the World network pioneered by the Rockefeller Foundation. In the SMR project, the following cities were part of the Tier 3 group: Athens (Greece), Greater Amman Municipality (Jordan), Greater Manchester (United Kingdom), Malaga (Spain), Malmö (Sweden), Reykjavik (Iceland) and Thessaloniki (Greece). Finally, the Tier 4 level of cities is represented by those cities potentially interested in the project tools (SMR, 2021).

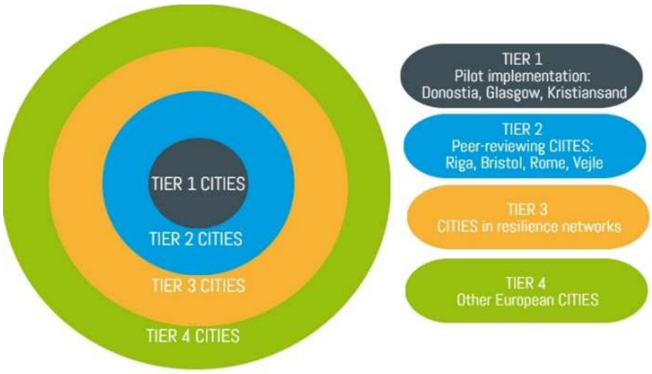

Fig. 2: The four different tiers of CITIES within the SMR project

During the co-creation activities and especially during the conducted stakeholder dialogues, all tiers of cities have been invited to participate in the standardization activities. However, due to the process of standardization, further cities and organizations interested in city resilience and the envisaged standards that are not related to the SMR project joined the standards development. Thus, the standardization activity increased the number of organizations and cities that validated the project's city-enhancing tools.

5.3 Comparison of RESIN and SMR projects

The results of this assessment of the RESIN and SMR project supports the development and enhancement of the co-creation and standardization activities within the ARCH project.

5.4 Combining the lessons learned in the ARCH project

Co-creation is at the heart of the ARCH project, and takes place in two contexts: within technical developments that are led by tool developers with the support of city partners; and in local activities that are spearheaded by city partners with the support of research partners. This twofold approach originated from the aim to make space within the project for not only research-driven developments, but also practical, "on the ground" development of solutions at the city scale. Accordingly, project partners worked to align tasks to ensure that technical developments and methods were appropriate or useful in confronting local challenges.

As an additional part of the co-creation aims of the ARCH project, the Mutual Learning Framework is an opportunity for exchange and sharing between the four cities that are part of ARCH's Consortium (Foundation cities) and a larger group of selected European cities, called the Keystone cities. These cities were selected because of their common interests in increasing the resilience of their historical areas. Both Foundation and Keystone are able to offer up and receive expertise during a series of four Mutual Learning Workshops (MLW), the main result of the Mutual Learning Framework. These interactive and dynamic workshops blend shared plenary discussions with more locally specific breakout sessions in city clusters that strategically match Foundation and Keystone cities with shared goals or challenges.

In addition to this co-creation approach, the ARCH project incorporates standardization, integrating it into nearly all of the other project tasks. To start, standardization-focused project partners have been included in tasks as "observers," and have led collaborative standardization activities during biannual project meetings and the activities of the Mutual Learning Framework, as mentioned above. To support the standardization activities in ARCH, the project will set up a liaison with relevant standardization committee(s) to ensure the uptake of the standardization outcomes of the project directly within the standardization system.

Altogether, co-creation and standardization are central to the methods of the ARCH project. In fact, early on in the project, co-creation tasks were bundled into a dedicated Work Package to ensure ease of coordination. This varied and strategic approach has ensured ongoing cooperation in the work of ARCH partners, and helped project outcomes to stay true to the aforementioned project principles of equality, openness, transparency, flexibility, inclusiveness and reflexive/iterative learning, trust, accountability and credibility (ARCH, 2020).

	RESIN project	SMR project
General		
How was standardization integrated in the project (resources, etc.)?	Standardization Work package Context: Only some technical partners (as well as ICLEI) and none of the involved cities had resources for standardization	Standardization Work package Context: All partners, including cities had resources for standardization Standardization addressed since project start, thus became more 'understandable' by all partners (despite their lack of previous experience)
How was the exchange with relevant (city) stakeholders organized?	Co-creation Work package with tasks focused on general process management, assessment reports, testing and documentation. Inclusion of stakeholders in standardization work only via (ad hoc) project meetings	Co-creation, pilot implementation and testing Work Package with tasks that focused on co-developing the tools having the input by all cities, development of manuals and handbooks to accompany the tools. Inclusion of external stakeholders through project meetings, training workshops and external events.
Reflection on conducted standardization and co-creation activities		
How successful was the stakeholder involvement approach (process)?	No explicit inclusion of (city) stakeholders in standardization processes. Where there was input, it was generally more indirect, coming in the form of results from the co-creation approach between researchers and city stakeholders, which then were transferred either to standardization work conducted by technical partners (e.g. inclusion of city perspective when commenting on the draft of a standard) or reported during project standardization meetings (i.e. meetings conducted for the standardization Work Package as part of other project meetings or as stand-alone meetings).	A number of cities and stakeholders were included in standardization activities, attended workshops and actively contributed to shaping three CWAs.
Which difficulties and challenges have been tackled?	Co-creation approach was not meant to be aligned with the standardization approach, as the standardization approach was more focused on technical partners (in part due to the initial project setup, wherein a less intensive co-creation approach was planned. Instead, a more traditional development and testing approach was planned. Identifying suitable results to standardize was difficult. Even when assigning personnel resources for standardization to city stakeholders, going the route of (individual) participation of organizations in standardization committees and transferring results this way was a challenge, as partners need to allocate time for these actions over a long period (potentially going beyond the project lifetime) which might conflict with their "business as usual."	Identifying which tools and processes would be standardized was a long process and demanded coordination with all partners. The CEN workshop participants made efforts to ensure the reliability and accuracy of the technical and non-technical content of all CWAs, but this does not guarantee the overall correctness of input, as it reflects their way of working and cooperating in their cities or organizations.
Impact of standardization outcomes		
How stakeholders benefit from the standardization activities, their results (impact of results)?	As some RESIN results were transferred to at least one international standard (although after the end of the project) applying these approaches makes sure that processes and methods in cities are aligned with other approaches, and also follow these aforementioned standards.	The SMR results were transferred into three CWAs on 'City Resilience Development' and then introduced to at least one international standard. More specifically, the indicators included in ISO 37123 'Indicators for Resilient Cities' were mapped along the five steps of the operational guidance cycle of CWA 17300.
Which are implications for the future?	Depending on what the desired outcome is (e.g. a "guideline" for a process vs. a more "technical" standard; a direct application in cities vs. a "blueprint" for methods or tools aimed at researchers), a direct alignment between standardization and co-creation would be desirable. This would include standardization tasks being specifically designed in a way to make use of co-creation. However, this can also require very coordinated timing of technical developments in the project, which might not be possible in an adaptive and agile co-creation process (e.g. in RESIN the focus switched from tool to method development).	With the publication of the CWA 17300 series, the topic of city resilience gained visibility. Due to the COVID-19 pandemic, this becomes even more timely. However, the SMR project has shown that, besides the classical research on existing standards and the development of research results out of standards, other benefits arise from the integration of standardization. Among these benefits is the standardization network of experts within the technical committee and the different options to support standardization work, which allows all relevant stakeholders to contribute to standards.

Table 1: Comparison of RESIN and SMR project

6 CONCLUSION AND OUTLOOK

The research on city resilience can only be impactful when all relevant stakeholders are included throughout the development of tools or processes. In recent years, standardization has come to have a major role in many research projects (especially those in Europe), where it is employed to support the dissemination and exploitation of project results. However, the ways in which a project can best exploit standardization to foster the integration of all relevant stakeholders has not yet fully researched. This paper provides practical examples of how co-creation and standardization can be conducted jointly, as reflected in the context of the ARCH project. The lessons learned of the RESIN and SMR projects were used via participatory action research to support the methodology of co-creation linked with standardization activities in ARCH – specifically within the ARCH Mutual Learning Framework. RESIN and SMR both have successfully integrated standardization in their respective project work, of which the SMR project was deemed by the European Commission as a success story for using standardization in an FP project (European Commission, 2019).

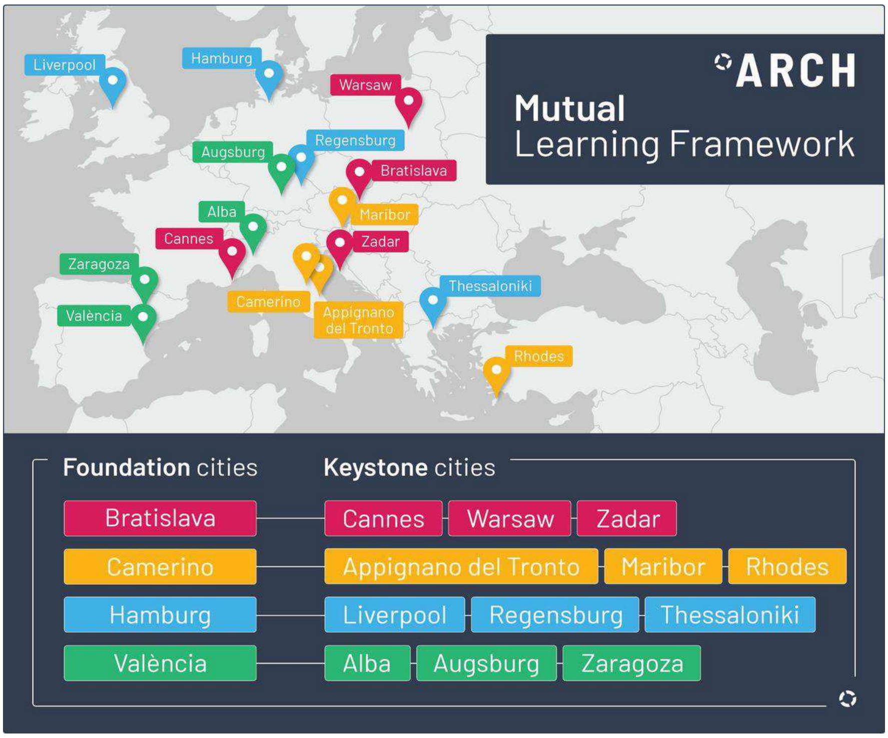

Fig. 3: Overview of cities involved in the ARCH Mutual Learning Framework (ARCH, 2021)

This research has some limitations, as few projects have thus far combined co-creation and standardization; and few among these with a focus on city resilience. The outcomes of this research will be important for the future activities to complement the CWA 17300 series on 'City Resilience Development,' with more resilience supporting standards. In this regard, the ARCH project is currently initiating further standard development within the frame of a CEN Workshop that is called 'City Resilience Development – Framework and guidance for implementation with a specific focus on historic areas' (ARCH, 2021).

The implications of this research should be part of future research on how to successfully integrate standardization in research projects, combining it with co-creation as well as on city resilience approaches in general.

7 ACKNOWLEDGEMENTS

This paper is based in part upon work in the framework of the projects "RESIN – Climate Resilient Cities and Infrastructures", "SMR – Smart Mature Resilience" and "ARCH – Advancing Resilience of historic areas against Climate-related and other Hazards". These projects have received funding from the European Union's Horizon 2020 research and innovation program under grant agreement nos. 653522, 653569 and 820999. 1 ABSTRACT

Urban green infrastructure is a key element in improving quality of life and creating an appropriate framework for sustainable, resilient and inclusive cities. Also, achieving a coherent spatial planning based on development of urban green infrastructure can be an useful solution to negative changes related to environmental quality, segregation and ecosystem services. We use church gardens in Bucharest as a case study to understand how these small green spaces can be integrated into urban planning.

The paper aims to analyse the potential of church gardens as recreation areas at city level in Romania. The analysis focused on three major aspects – the spatial distribution of churches, the accessibility of green spaces located in church gardens (calculated both for adults and elderly people as most important groups accessing the gardens) and the characteristics of those gardens in terms of facilities, use and problems (based on a field survey filled for a 20% sample of the 287 churches in Bucharest).

The results showed that the homogenous spatial distribution of churches with green gardens makes them accessible for residential areas located far from traditional green recreational areas. In Bucharest, the service areas of churches with green spaces cover 84% of the residential areas when accounting for the adult's walking speed and 61% when accounting for elderly people. Green spaces in church gardens amount to over 25 ha in Bucharest, with an average of 1737 square meters per garden, representing a surface which could be designed to respond better to the population needs. The major challenges identified in the church gardens are (a) the use of green space for other purposes than recreations, such as storage space for construction materials (31.5%), waste (17.5%), temporal constructions (12.3%) or car parking (21%), and (b) quality of vegetation.

Our study highlights that through their number and distribution church gardens can represent an alternative to large green areas if they are opened to the population and used for organising activities and events. Their importance and potential could be increased if designed for such purpose. Such analysis can be useful in the planning process of small urban green areas in order to integrate them into urban management process.

Keywords: recreation, accessibility, church gardens, green infrastructure, inclusion

2 INTRODUCTION

The new 2030 Urban Agenda and the Sustainable Development Goals SDGs (specifically SDG 11) reveal the need for public green space interventions to achieve sustainable urban development (UN, 2015). Such actions are required in order to achieve sustainable, resilient and inclusive human settlements which is the goal of multiple international initiatives.

Urban green spaces are highly important both from ecological and social perspectives (Kabisch and Haase, 2013). From an ecological point of view, they provide regulating and supporting ecosystem services, such as climate mitigation (de la Sofia et al. 2019; Jarosińska and Gołda, 2020), regulating the temperature of the indoor and outdoor environment (Liberalesso et al., 2020; Wang et al., 2014), flood control (Latinopoulos et al., 2016; Sun et al., 2019), noise reduction (Sakieh et al., 2017), pollution control (Ariluoma et al., 2021), and providing a habitat for urban biodiversity (Tzoulas et al., 2007, Jabben et al., 2015). The social benefits provided by urban green spaces are related with opportunities for recreation, nature observation, socialisation, artistic, educational and scientific activities, sports and their role in improving both physical and mental health (Dickinson and Hobbs, 2017; Kabisch et al., 2017). Moreover, urban green spaces increase aesthetics and quality of life (Enssle and Kabisch, 2020; Razak et al., 2016).

In the past decades, many studies have focused on the analysis of large urban green spaces, mainly parks and urban or periurban forests, addressing various topics such as the services they generate (Demuzere et al., 2014), their potential to control pollution (Saaroni et al., 2018), their role in promoting social cohesion (O'Brien et al., 2017), the planning principles behind them (Gradinaru & Hersperger, 2019) and administrative aspects (Meerow and Newell, 2017). There are also studies related to the connectivity of urban green spaces and the integration of these areas into spatial planning (Langemeyer et al., 2020) in order to increase the green surface within the cities.

The new paradigm of urban growth promotes compact cities as solution for reducing the human impact on the environment by controlling urban sprawl, preserving natural and seminatural areas around cities and minimising the need for private transportation (Artmann et al. 2019). However, these cities have to include enough green areas to compensate for the deep human transformation and the pollution generated. The development of compact and green cities faces many challenges, such as the existing high density of previously built areas, the high number of inhabitants and the property regime of urban spaces, with many falling under the realm. In this context, small urban green spaces could represent a viable alternative to parks and urban forests and a potential solution for environmental issues in urban areas, especially since they can be developed both independently and complementary to other urban functions (e.g. institutions, commercial areas, residential areas). Peschardt et al.(2012) defined small urban green spaces as places that must have at least some vegetation, their own entrance, and distinguishable boundaries which separate them from surrounding public space. Also, Peschardt and Stigsdotter (2013) mentioned that for a green space to be considered small it must have an area less than 5000 square meters.

Small urban green areas include categories such as pocket parks, residential green areas, playgrounds (Olsen et al., 2019), institutional gardens such as school gardens (Ioja et al., 2014) or church gardens, green roofs (Langemeyer et al., 2020; Shafique et al., 2018) and green walls (Fastenrath et al., 2020). The scientific interest in these areas varies a lot according to the intensity of their use, the targeted population, their frequency in urban areas and the challenges related to their inclusion in a coherent network. Playgrounds, for example, are a hot topic, many studies are focusing on their role, both positive (place for physical activities and contact with nature) (Cohen et al., 2020; Raney et al., 2019) and negative (spaces which may contain chemical contaminants or parasites from other species) (Berman et al., 2018) in children's health.

Church gardens are not a frequently discussed topic in the scientific literature. There are several publications which analyse more widely subjects like church gardens, cemeteries or sacred forests (Byers et al., 2001; Rae, 2021). Most of the publications focus on their contribution toward increasing urban biodiversity (Skorka et al. 2018) and recreational and regulation functions of the cemeteries. Also, they provide valuable information regarding their evolution, floristic characteristics and socio-cultural use (North et al., 2017).

Since in Romania church gardens are considered a distinct type of urban green areas within the broader category of institutional gardens (Romanian Parliament, 2007) we explored their potential to improve the residents' quality of life through cultural ecosystem services. A study in Poland showed that church gardens could perform new functions related to recreation and education, they could contain playgrounds for children, secular exhibition and animal cribs related to traditional holidays (Kaczyńska, 2020). As yet the cultural services provided by urban sacred sites have not been examined in urban sustainability debates, they require investigation because urban sacred sites are often managed for different objectives then other formal urban green spaces.

Only few studies have focused on the potential of small green spaces in increasing the connectivity and multifunctionality of urban spaces (see for example Ioja et al., 2014). Our study will focus on church gardens with the aim to fill the gap related with the assessment of their potential to represent a valuable recreation alternative in cities. The objectives of the paper are to: (1) assess the spatial distribution of church green spaces in Bucharest, (2) evaluate the accessibility of church green spaces for the local community and (3) identify the characteristics of church green spaces and their potential for representing valuable recreation alternatives.

3 STUDY AREA

Bucharest is the capital city of Romania, the largest city in the Central and Eastern Europe. It has a population that exceeds 1.83 million inhabitants (Eurostat, 2019) and a surface of 242 square km. Bucharest was a capital for the past three and a half centuries and this status is visible in the planning and design of the city. After the fall of the socialist regime in 1989 the centralised planning system was replaced by chaotic development and urban sprawl due to the shift to private ownership of land and the weak legislative system (Grădinaru et al., 2020).

After 1989 the surface of urban green infrastructure in Bucharest diminished as a result of land conversion into commercial and residential areas (Iojă et al., 2014). Urban parks have lost around 60 hectares between 1989 and 2019, currently covering around 790 ha (Badiu et al., 2019) but small green areas have been equally threatened especially due to the restitution process that affected pocket parks, neighbourhood greens and other areas which once transferred into private property were transformed into built areas (Onose et al. 2020). Due to public pressure related to urban green spaces, in the last years emerged a tendency of creating new green areas, most of them located on previously abandoned land within or near residential areas.

Many churches in Bucharest are centuries old and represented a vector of urbanisation preceding the building of the residential areas they are currently serving. During the socialist era, in the context of an outspoken opposition between state and church, many churches in Bucharest were demolished, moved or their gardens were diminished making place for the socialist blocks of flats or major transport infrastructure. Most of the churches in Bucharest are Christian orthodox, they are usually physically separated from other urban functions and not always open for the public.

4 METHODOLOGY

We developed a spatial database containing the location of the churches in Bucharest, including all categories of churches (e.g., orthodox, catholic, protestant) located in independent buildings. We used two sources of information: the website of the National Heritage Institute (CIMEC, 2008) and the Open Street Map database (retrieved online from the Geofabrik website). The location of each church was validated using the satellite base map provided by ESRI in ArcGIS Pro (ESRI, 2018). The spatial database contained the build-up area within the church garden and the green space (excluding cemeteries) and information regarding the names, confession, categories of green areas and vegetation coverage and surface.

We identified and validated 287 churches in Bucharest, most of them belonging to the following confessions: Christian orthodox (77%), Christian catholic (3.14%), Baptist (4.53%) and Adventist (5.92%). We also identified 25 places of worship of other confessions. We included in the analysis only the stand-alone locations and excluded the ones arranged inside residential buildings or multifunctional ones.

In order to perform the accessibility analysis, we built a Network dataset based on the open access street layer provided by Open Street Map. The network was configured for walking and included two alternative modes – for adults and elderly people, these two categories being the most probable to use church green areas since they visit these places more often. Based on a literature review, we used an average walking speed of 0.8 m/s for elderly people (Montero-Odasso et al, 2004) and 1.42 m/s for adults with normal weight (Browning et al, 2006). We performed the accessibility analysis using the Service Area wizard in ArcGIS Pro 10.2 and highlighted areas at 5-, 10- and 15-minutes walking distance (see Table 1) from the churches having a green area in their garden. We also calculated the surface or collective and single-family residential areas located in the delineated service areas to highlight the share of urban population having access to these objectives and the potential they have to represent recreation areas.

	Distance walked in 5 minutes (m)	Distance walked in 10 minutes (m)	Distance walked in 15 minutes (m)
Adults	240	480	720
Elderly	427	854	1282

Table 1: Distances used in the accessibility analysis derived based on the average walking speed for adults and elderly people

To identify the characteristics of the gardens, we conducted a field survey to a sample of 57 churches, representing 20% of the total number. The field work was carried out during the summer season (June-July 2020) so aspects related with the green areas could be observed. The survey included items addressing (1) general information about the church (i.e., confession, surroundings, establishment period), (2) characteristics of the gardens (i.e., endowments, use of the garden) and (3) green space characteristics (i.e., categories of green spaces, floral composition, vegetation problems). Statistical analysis was used to analyse the information.

5 RESULTS

5.1 Spatial distribution of church green spaces in Bucharest

Our analysis highlighted the concentration of churches in the old central part of the city, almost half of the identified churches being located inside the first ring of the city, a surface of around 28 square km representing less than 10% of the city's surface.

Only 52% (149 locations) of the churches identified in Bucharest have green spaces within their gardens, with great variations between confessions (Fig. 1). Christian orthodox churches represent 92% of the 149 locations that have green spaces and 62% of those which don't (85 out of 138). The orthodox confession is the only one for which the churches with green spaces are in greater number (almost 60%) than those which don't.

It is interesting to notice that, contrary to the confession, the location of the church doesn't significantly influence the presence of the green space. Therefore, 53% of the churches located inside the first road ring of the city, and 50% of those located outside, have green spaces within their gardens.

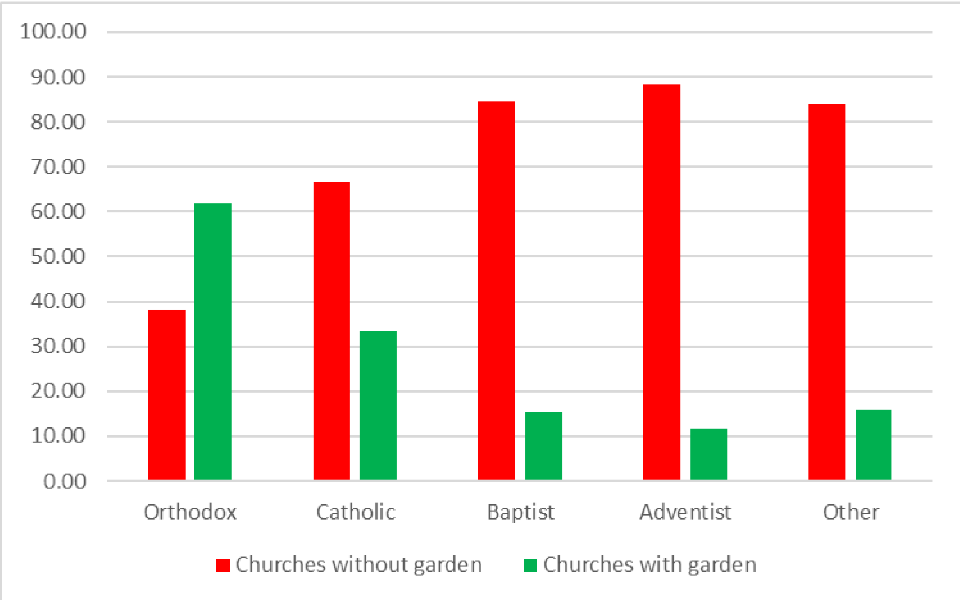

Fig. 1: Distribution of green spaces between churches of different confessions

The surface of the green spaces located within the gardens varies from a few square meters to 1.84 ha (18400 square meters), with an average value of 1737 sqm of green space per garden. Overall, green space located within church gardens in Bucharest have a surface of 25.71 ha.

5.2 Accessibility of church green spaces for the local community

The accessibility analysis highlighted the high potential church gardens have as recreation alternatives for the local population. Even if only half of the identified churches have green areas inside their gardens, they are homogenously distributed at city level and could serve as recreation areas for an important number of residents.

There are significant differences in terms of accessibility between the two groups included in analysis. Adults, who walk faster, enjoy a good accessibility to churches with green areas inside their gardens across the city. Only far peripheral areas lack churches with green spaces, some of them actually lacking churches at all. The situation changes when taking into consideration the limited mobility of elderly people. Apart from the old central part of the city, which is enclosed by the first road ring, almost all neighbourhoods have areas without access to churches with green spaces from the point of view of elderly people (Fig. 2). Their limited mobility heavily restricts the distances they can cover in a given amount of time and also their resistance to effort.

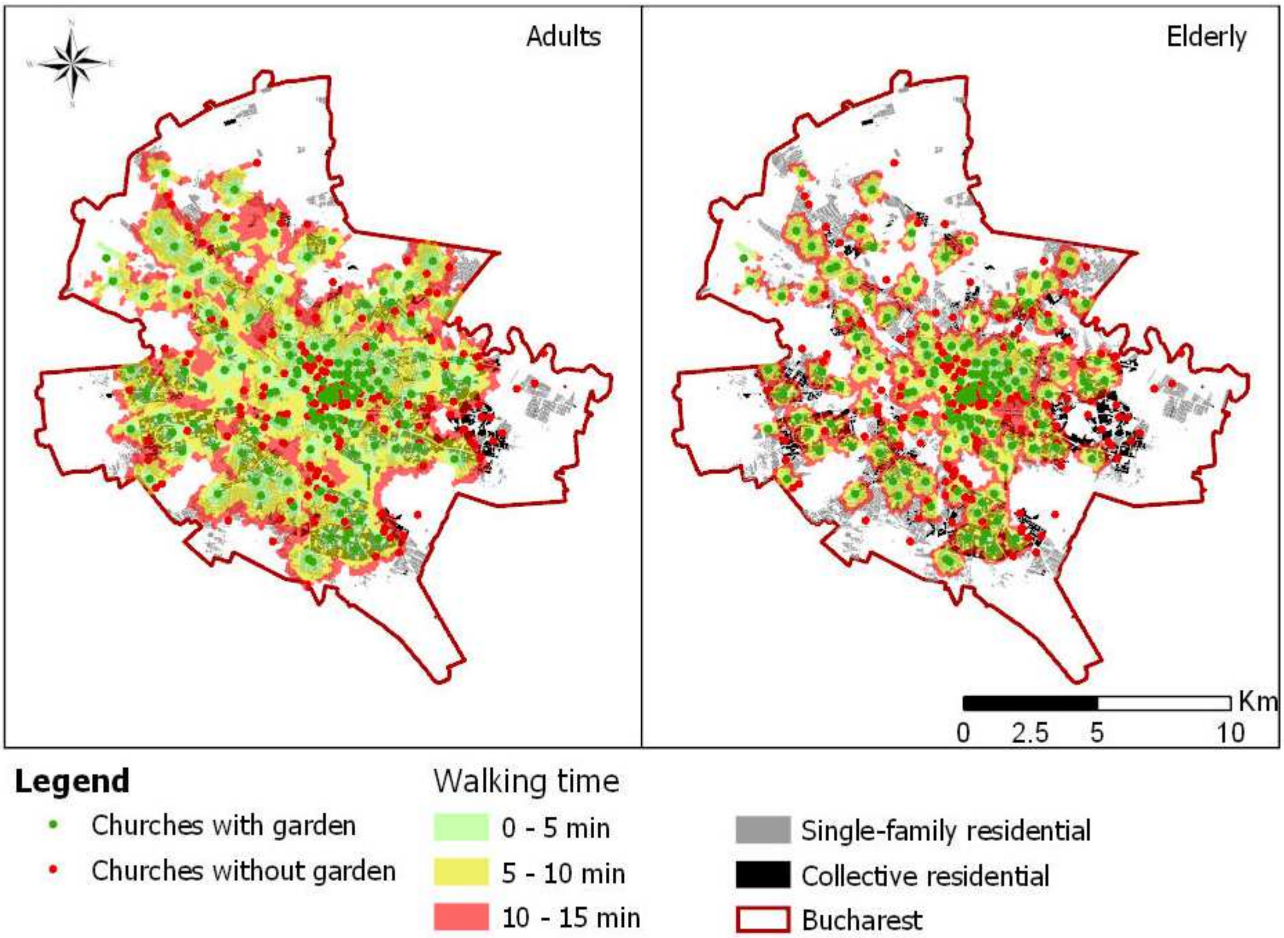

Fig. 2: Service areas of churches with green spaces in their gardens (calculated for adults (left) and elderly people (right))

We assessed the surface of residential area located in the proximity of churches with green spaces in their gardens as measure of the percent of population with access to them (Table 1). The analysis showed that in case of the services areas established for adults, only 13.79% of the residential areas had very low or no access to green areas in churches gardens. Collective residential premises have a better access to green areas in church gardens then single-family homes, 93% of the former having very good (less than 5 minutes), good (5-10 minutes) and satisfactory (10-15 minutes) access compared with only 82% among the latter. It is interesting to highlight that, for both categories of residential areas, the larger surfaces are found in the immediate proximity of churches, with double or triple extension in the first two areas of access (under 5 minutes and 5-10 minutes) compared with the third one (10-15 minutes).

Walking time	0-5 min		5-10 min		10-15 min		over 15 min		Residential surface
Unit	ha	%	ha	%	ha	%	ha	%	ha
Adults									
Collective residential	942.03	37.30	1021.943	40.46	378.34	14.98	183.287	7.26	2525.6
Single-family residential	1258.91	32.06	1287.5	32.79	674.11	17.17	706.37	17.99	3926.89
Total	2200.94	34.11	2309.443	35.79	1052.45	16.31	889.657	13.79	6452.49
Elderly									
Collective residential	418.36	16.56	689.1	27.28	645.22	25.55	772.92	30.60	2525.6
Single-family residential	652.77	16.62	788.78	20.09	747.1	19.03	1738.24	44.27	3926.89
Total	1071.13	16.60	1477.88	22.90	1392.32	21.58	2511.16	38.92	6452.49

Table 2: Surfaces of residential areas located inside the service areas of churches with green spaces in their gardens

In the case of the service areas established for elderly people, the distribution of the residential areas is more balanced. An important share of the residential areas doesn't have access to green spaces in church gardens – 30.6% in the case of collective residential and 44.27% in the case of single-family residential. The results showed that around 17.5% of total residential areas (20.7% of collective residential and 15.4% of single-family residential) has very good access to green spaces in church gardens for adults, but not for elderly people (Fig. 3). The same situation is also characteristic for 12.9% of residential with good access (5-10 minutes walking distance) in the case of adults, but not in the case of elderly people. In contrast, the residential surfaces with satisfactory (10-15 minutes walking distance) and low access (over 15 minutes walking distance) are larger in the case of elderly people.

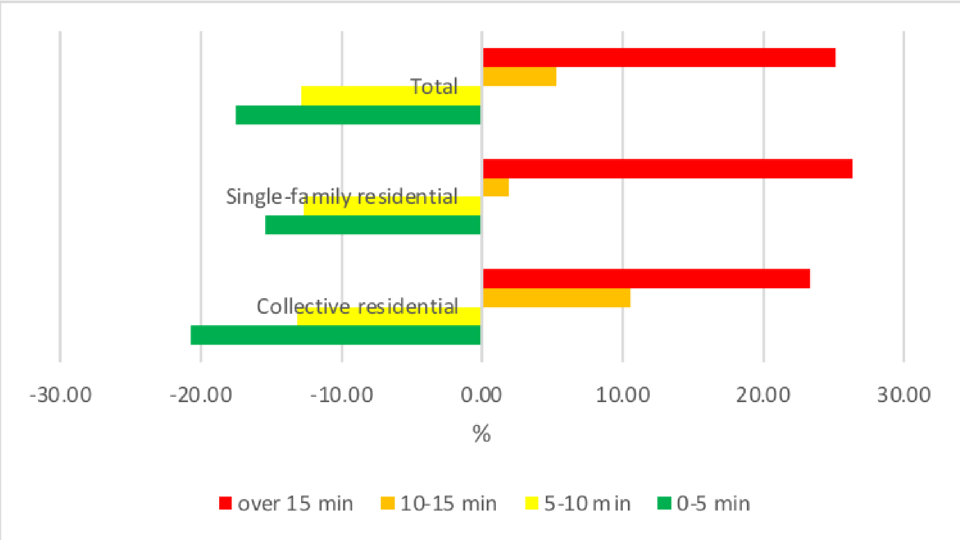

Fig. 3: Difference between the shares of residential areas inside the services areas calculated for the elderly and for the adults

5.3 Characteristics of church green spaces

The field survey highlighted that the most common urban functions found in the proximity of churches in Bucharest are collective residential (86%), single-family residential (51%), commercial areas (42%) and parking lots (37%).

Beside the main building, church gardens enclose a variety of land uses within their perimeter, such as buildings used for rituals (e.g., outdoor worship, weddings, burials, shrines and so on), bell towers, alleys, parking lots, green spaces, statues and playgrounds. The diversity of these elements depends on the church confession and age, the available surface and the protection regimen of the location. The majority of the surveyed churches had a private garden (85%), but these gardens did not always include green areas. Some of the churches without garden are located within cemeteries which generally can't be associated with recreational activities.

The vegetation in church gardens is diverse, the majority including hardwood species (82%), coniferous (58%) and shrubs (79%) and sometimes very dense. Commonly, shrubs can be used as a green alignment which separates alleys and green spaces or are used as a replacement for hedges. The lawn is another common green element, encountered in 74% of the surveyed cases. The grass areas cover between 0 and 90% of the gardens' surface and from case to case the degree of maintenance varies. Almost half of the sample is characterised by the presence of flowers, both in flowerbeds or in hotchpotches. Church gardens are characterised by the presence of some random recreational elements like benches and playgrounds.

The major issues identified in the church gardens are (1) the use of green space for other purposes, such as storage space for construction materials (31.5%) or waste (17.5%), presence of temporal constructions (12.3%) or car parking (21%) and (2) low quality of vegetation. Around half of the gardens have problems related with dry vegetation, either advanced (43%) or medium (7%) and 11% host invasive plant species (e.g., Ailanthus altissima). Almost 20% of the gardens don't have any problems and 23% are facing other categories of problems (Fig. 4).

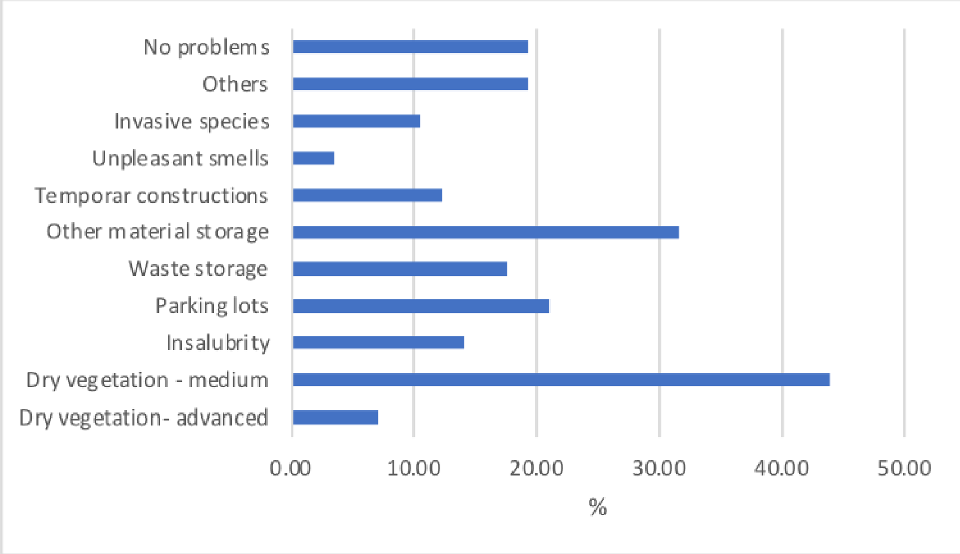

Fig. 4: Percentage of church garden issues

6 DISCUSSION

Using Bucharest as a case study, we showed that church gardens can represent a valuable recreation alternative. Currently, only around 50% of the churches in Bucharest have green spaces in their gardens. This is partially due to the transformations suffered in the socialist era, but also to the financial capitalization of all resources, to the changes in legislation and consumption patterns of the society and to the lack of awareness related with the determinants of a high quality and healthy urban environment. In the last years many administrators chose to transform the green spaces in chapels since the need for this category of services has increased.

Collective residential has the highest accessibility to green spaces in church gardens. This is due to the fact that these areas were almost entirely built during the socialist era and therefore planned from the beginning to include all necessary services. They were usually built on older single-family residential areas from which churches were the only preserved buildings. Single-family residential areas can be planned (especially the historical lots) or unplanned, especially the newly built ones and therefore their access to churches widely varies.

The high number and the homogenous distribution in the city, could make church gardens an interesting and feasible option for recreation and social activities despite their small surface (approximately 3% compared with urban park surface in Bucharest). The accessibility analysis showed a high potential of church gardens to represent a nearby and easy to reach green area especially for adults. The limited mobility of elderly people makes this option suitable only for around half of them, but it is important to mention that some residential areas with good and very good access to church gardens are located outside the area of influence of urban parks. Therefore, the green areas in church gardens could represent the places where elderly residents from these neighbourhoods could experience nature.

Church gardens can provide both regulatory and cultural ecosystem services. Depending on the gardens' arrangements and endowments, they can host a wide variety of recreational activities (e.g. playgrounds, lecture clubs, places for boardgames, places for meditation, social spaces), but they can also improve the aesthetics of the neighbourhood and population wellbeing (de Lacy and Shackleton, 2017). Currently there is almost no infrastructure meant to increase the role of these spaces in social activities. Less than half of the gardens have such infrastructure and it is mainly represented by benches. Financial aspects are generally directly related to the design and activities carried out inside church gardens. The greatest challenge related to church gardens is to stop their transformation into artificial areas and to reverse the process in those areas where it is still possible. Another important aspect is related with the fact that part of the church gardens is only opened to the public during service, which seriously affects their potential of representing places for social interaction.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Our study highlights that through their number and distribution church gardens can represent an alternative to large green areas if they are open to the population and used for organising activities and events. Their importance and potential could be increased if designed for such purpose. Our findings are in line with research conducted on other small urban green spaces, such as school green areas (Ioja et al 2014) and pocket parks (Nordh and Ostby, 2013). Information on their distribution, accessibility and characteristics can be useful in the planning process of small urban green areas in order to integrate them in urban management process.

Greening the church gardens could contribute, beside the already discussed socio-cultural role, to increasing the amount of regulatory ecosystem services these areas provide minimising the negative effects produced by rainfall water (Saaroni et al, 2018), the level of noise generated by outdoor services and the heat island effects. These improvements could also contribute to minimising the potential of conflict occurrence involving churches.

One of the limitations of the study is the lack of spatial representation of the population number which was replaced by the surface of residential area by category. Also, the study didn’t consider the availability or reservation of people to use green areas in church gardens as recreation areas nor the fact that church gardens are sometimes private property and therefore not necessarily available for public use.

7 CONCLUSION

The surface of green areas inside church gardens is rather small in comparison with urban parks, urban forests or other categories of green areas within the city. However, due to their number, the good position they have in relation with the residential areas and their high accessibility, this category of small green areas has the potential to become an important element within the city if properly designed and maintained. The aesthetics and management of church gardens must comply with certain regulations if they are to be integrated in a coherent spatial urban planning.

Church gardens may represent an alternative to traditional green areas through the services they could provide since they could be designed to fulfil spiritual and religious needs ensuring a peaceful environment. Such needs aren’t properly satisfied in crowded urban parks where the surface is often insufficient to host all categories of activities.

Our study could represent a starting point in planning and designing church gardens as part of the urban green infrastructure and in giving them a higher importance from a socio-cultural point of view.

1 ABSTRACT

Availability of reliable data is one of the most important elements for fact-based decisions. Urban planning and spatial energy planning often suffers from a lack of availability of good, validated and up-to-date data sets. Furthermore, integrated spatial and energy planning needs to incorporate new spatially distributed energy sources and understand how these sources can be used in the future to meet climate protection targets. These new energy sources can be, for example, waste heat from industrial food production, local industrial/commercial enterprises, data centers, or urban infrastructure such as tunnels and metro stations. The utilization of such waste heat sources in heating networks has been demonstrated several times, however, their proper identification in an urban environment can be challenging, especially for smaller and unconventional sources (Schmidt, 2020).

Gamification as an innovative way to collect the needed data was investigated within a national funded research project called "HotCity". Gamification builds on the use of game mechanics in contexts that are, by nature, unrelated to the game (Deterding, 2011). Within the project the HotCity-App was developed enabling users to spatially report and evaluate different sources of waste heat. The gamification of data collection was also intended to raise awareness of waste heat and energy use on the one hand, and to facilitate the collection of data from small energy sources on the other. For the first time, the game framework is secured using a blockchain and mapped by means of a token[1] system. The HotCity-App was tested in the Austrian cities Vienna and Graz as a proof of concept to analyse if and how the gamification approach can deliver valid results.

The HotCity-App, the game, makes it possible to identify and georeference also smaller sources of waste heat in order to use the available energy. Two test runs were each conducted in Graz and Vienna, which provided helpful feedback from the testers regarding promising features as well as showed barriers reducing the success of this data collection approach. An interactive web-application for the data collected with the HotCity-Appwas further developed to visualize the reported potential waste heat sources and to interactively evaluate the economic feasibility of using the waste heat sources under different frame conditions.

The paper will elaborate the game development, discuss the gamification approach and the lessons learned during the proof of concept project. We will further give an outlook of additional data types for integrated urban energy planning, which could be collected by this approach.

Keywords: mobile app, waste heat, energy planning, data collection, gamification

2 INTRODUCTION AND CHALLENGE

The energy system of the future will consist most likely of many different decentralized units (e.g. rooftop PV panels, individual heat pumps etc.). For the development of districts with high energy efficiency and

[1] https://en.bitcoinwiki.org/wiki/Token, tested 07.06.21

increased use of locally available and sustainable energy sources, a detailed spatial identification of possible energy potentials is necessary in order to plan cost-efficiently and future-proof. In particular waste heat from industry (foundries, food production...) and commerce (data centers, supermarkets...) as well as urban infrastructure (tunnels[2], metro stations[3]) can make an important contribution to heating and hot water production in plus-energy districts. While "low-hanging-fruits" such as waste heat from large scale industrial plants are already widely used, the identification of smaller sources is associated with various difficulties (Schmidt, 2020). Many larger cities already have a data set, e.g., Open Government Data, which is usually not up-to-date enough, not sufficiently detailed (spatially) and often does not contain all necessary data. Due to the often chosen top-down methodology for the identification of the waste heat potential, i.e., using a survey of the largest pollutant emitters (e.g. Brueckner etal., 2014), smaller sources are not recorded, which therefore do not appear in these databases.

Gamification, on the other hand, offers the possibility of generating targeted incentive systems for data collection (crowdsourcing/crowd collecting). Games like "Pokemon Go" have shown which undreamt-of dynamics can be created.Within the project HotCity funded by the BMK[4] a Game (the HotCity-App) was developed, enabling users to spatially report and evaluate new potentials of waste heat. The application to collect waste heat was chosen to be exemplarily for other spatial energy data. The gamification of data collection for waste heat was also intended to raise the general awareness of the topic and to facilitate the collection of data from small energy sources that are normally not considered in top-down methodologies.

2.1 Gamification as a bottom-up method for identifying energy-oriented data

The massive distribution and market penetration of digital games (approx. 37 billion dollars in sales in 2020 in the USA alone as stated by Statista, 2021) is impressive. For example, 510 million people are currently actively playing games (5.3 million in Austria as stated by ÖVUS, 2019), with an average age of 35. Gamification is based on the use of game mechanics in contexts that are, by nature, unrelated to games (Deterding, 2011). The aim of gamification usually is to apply the motivational and feedback techniques that have been tried and tested in games. Games provide clear goals (Hunicke et al., 2004; e.g. quests), they reward (Vorderer et al., 2004; e.g. badges, level-ups), they allow to compete or cooperate with others (Yee, 2006; e.g. in the form of rankings, multiplayer elements) and they provide an interactive framework for different experiences and skills (Ivory & Kalyanaraman, 2007; Jansz, 2005).

Gamification has already been successfully used in various application areas to promote participation, such as in the context of civic courage (Coronado & Vasquez, 2014), citizen participation (Thiel & Lehner, 2015), e-learning (Barata et al., 2013) and e-government (Al-Yafi & El-Masri, 2016). The application of gamification has also yielded positive results in the mobility sector, e.g. in terms of promoting sustainable forms of mobility (Kazhamiakin, Raman et al., 2015).

Pfeiffer et al. (2020) coined a new definition of Gamification: “Gamification is the use of game mechanics as a further dimension within and around both gaming and non-gaming contexts, in an endeavour to nudge participants to perform certain actions, by adopting a playful attitude”. This definition shows that gamification can also take place within games, whenever further elements outside the core mechanics and the core storyline are used to get the players to explore certain content. Furthermore, the definition also shows the relation to the principle of nudging and that gamification can be seen as one of the tools to trigger behaviourchange.

2.2 Blockchain Technology as a transparent way of handlingreward systems

Due to its decentralisation, transparency and security is the blockchain technologyoften part of technological and social discourses (Buhl et al., 2017) and is being treated as a disruptive innovator for a wide range of applications: from transaction processing to land registry entries to logistics chains, the intermediary is to be eliminated in the future (Hopf & Picot, 2018). Previous crypto technologies such as Bitcoin and Ethereum rely on "proof of work" and reward "miners", who keep the entire network alive and validate all transactions, for solving randomly generated computing tasks. The computing power required for this increases linearly

[2] https://sciencev1.orf.at/science/news/154441.html tested 07.06.21
[3] https://www.reuseheat.eu/berlin/tested 07.06.21
[4] Federal Ministry Republic of Austria for Climate Action, Environment, Energy, Mobility, Innovation and Technology

with the difficulty of the computing tasks and consumes more and more resources. This is where new blockchain technologies such as "Ardor" or "NXT" come into play, which are based on a "proof of stake" algorithm and are much more energy-efficient. Here, it is not about computing power in the form of graphics card performance or CPU-power, but about holding a certain stake in the network-maintenance token, other aspects like the total time of taking part as a verification node and a certain aspect of randomness. Regardless of the approach, the peer-to-peer principle, the strong encryption and the permanent and validatable storage of information represent an opportunity for diverse industries - including, of course, the gaming industry (Pfeiffer et al., 2020).

Ardor offers the possibility to generate utility tokens on the child chain Ignis. Approval models can be set up around these created tokens and therefore the set of rules can be specified. Furthermore, there is the possibility to develop smart contracts. As a bonus, there is also a ready-made marketplace that can be used within the scope of the decentralised applications (DApps) generated using the Ardor blockchain and its child chain Ignis.

In HotCity, the blockchain was used to prevent cheating on the one hand and to ensure transparency for the players on the other. It was used to automate the management of redeemed prizes and rewards and to reduce the administrative effort to a minimum. The concept involved incentives (such as coffee vouchers) - mapped on a blockchain token - that could be redeemed at project partners. Double spending or counterfeiting of vouchers can thus be avoided. In addition, the accounting settlement can be automated. For example, similar to a current accounting system, the partners could send the tokens to our billing account on a monthly basis, thus triggering the transfer of Euro funds from the game operator to the prize provider.

The blockchain system for the HotCity-Apphad to meet the following basic requirements:

- It must be a fully decentralised public blockchain.
- Users can, if they want, run a node of the blockchain on one of their devices, such as a laptop or mobile phone.
- We can use approval models to ensure that various conditions are met. One of these conditions is that the tokens cannot be transferred to other unregistered wallets.
- Identity management can potentially be implemented. In our case, this would be a possible connection of decentralized identifiers[5] (DIDs).
- Users do not need cryptocurrencies to pay network fees, we can take care of this as an operator with bundling accounts.
- Individual transactions must be manageable in terms of costs, even if the crypto market fluctuates massively.
- Messages attached to transactions must be encryptable.
- However, it must be possible to generate shared keys. To make the information readable for authorised parties.
- It needs the possibility to programme lightweight smart contracts, in our case it is the exchange of the different token classes, as part of the game mechanics.

3 THE HOTCITY APP

3.1 GameMechanics &Dynamics

The basic idea of the HotCity App is that users can move through the city and identify possible waste heat sources. In the past, a good understanding has been developed of possible waste heat sources and their characteristics. Chimneys indicate the location of (industrial) processes using combustion and might therefore generate waste heat; and recooling units indicate large waste heat potentials from data centres or other cooling processes. Users of the HotCity App can identify chimneys and recooling units by taking a photo or doing some internet research, e.g. using Google Mapssearch.

[5] https://www.w3.org/TR/did-core/#dfn-decentralized-identifiers tested 07.06.21

The user (the player) can take a photo in the HotCity App to identify the object of a possible waste heat source. Additionally, the user also needs to provide information about the type of object (chimney, recooling unit). The user can then mark the exact GPS position of the object on the map. The last step for the user is to crop a satellite image of the set GPS position only showing the waste heat source. After that the potential waste heat source is saved to the map of the game and the user is rewarded with heat tokens. Now every user can give additional information about this specific waste heat source andverify the object,its size, height and number of units.

The cities where the game can be played are segmented in areas through a grid. Each area can be conquered by a single player or a team. The player or team with the most identified waste heat sources wins the area.

The gamification concept is also extended through a high score system for single players and teams based on their heat score (a number calculated based on the user's earned tokens – see next paragraph). The heat score from earned tokens also unlocks numerous badges (e.g. "Heat Runner", "Heat Scout", "Conqueror") inside the app. The head score also puts gamers into a ranking system (e.g. "Rookie", "Amateur", "Master")

The app also incorporates a basic voucher incentive system, where earned tokens can be redeemed for voucher of partners (such as coffee to go).

All those features add additional layers of gamification elements to the app (see also next paragraph).

The gamification framework consists of three utility tokens realised within the blockchain Ardor and its child chain Ignisthat represent points: bronze, silver and gold tokens. Users receive bronze tokens for simple tasks such as uploading unconfirmed images and later receive points with higher value, when heat sources are confirmedby other payers. These tokens can later be redeemed for incentives, with better incentives distributed for gold tokens than for bronze tokens. As a further game mechanic, tokens can be exchanged for each other, e.g., 10 silver tokens result in 1 golden token. Furthermore, all badges are displayed as tokens.

3.2 App Development

3.2.1 Frontend of the HotCity App

The HotCity App uses a hybrid app technology with a single code base based on the hybrid app framework Ionic including Capacitor[6] as container, which delivers the app to different platforms (in this project iOS and Android).

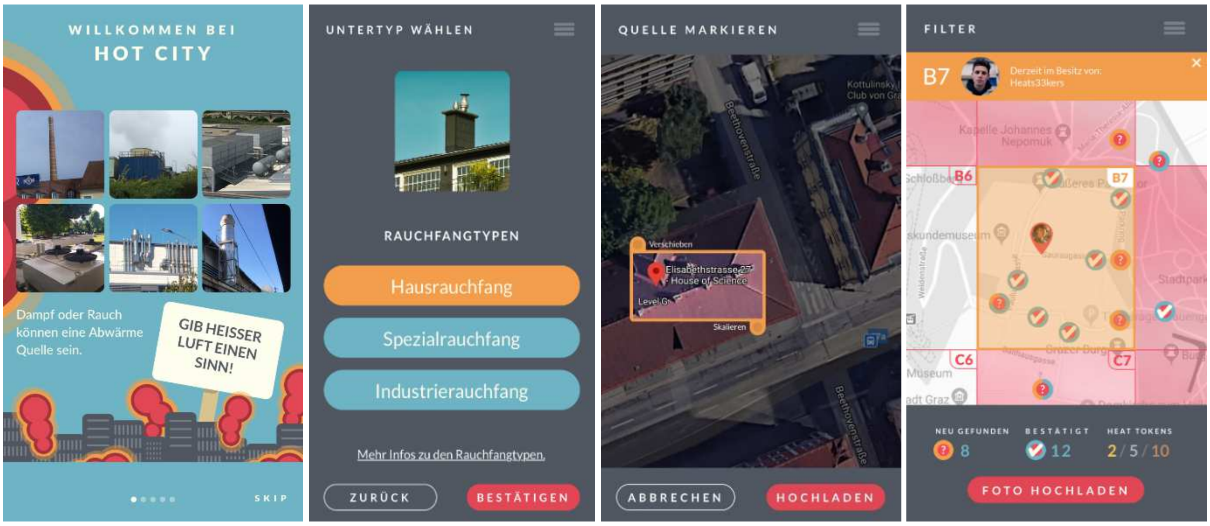

Fig. 1: HotCity App Screens

The structure of Ionic is web-based (HTML5, CSS3 & Sass[7]), based on Angular (JavaScript/TypeScript) and uses an open-source mobile user interface component toolkit as well as several plugins to bridge native functionalities with the web-based code base. As a framework, Ionic offers a cross-platform delivery feature set to address the native functions of the operating systems such as camera, GPS or memory. In addition,

[6] Capacitor is a cross-platform native runtime for web apps and provides native app container for packaging and deploying Ioinic apps to various mobile and desktop platforms. https://capacitorjs.com

[7] https://sass-lang.com/

native SDKs can be easily integrated. This serves as a solution for smartphones of newer generations (Android > 4.4, iOS > 10). Another advantage is the development using web technologies, so that the apps developed in Ionic can also be made available as a PWA.[8]

The app is connected to a backend via an API to process data collection, data enrichment, user profile information and blockchain related verification mechanisms for gamification (see next paragraph). The following figure shows main screens of the HotCity App.

3.2.2 Backend of the HotCity App

The actual transfer of the respective assets takes place entirely on the blockchain. A lightweight contract (cf. smart contract) was developed for this purpose, which, in conjunction with the API, ensures that the assets are transferred correctly.This contract is initially triggered by the backend and contains, for example, information about which "heatspot" has triggered an asset transfer. The lightweight contract then calls the API and checks whether the entries and information are valid and correct and then transfers them. In a freely definable period of time, the API checks whether the asset transfer was successful. If, for example, the transfer of the assets fails due to technical circumstances or insufficient fee, a new process takes place.

The Ardor node primarily manages and executes the lightweight contracts for the transfer of the application. As already mentioned, the API acts as a validation unit for this contract and only transfers assets or badges if the correct information is available.

In summary, blockchain technologies in the HotCity project secure those relevant parts of the game where values for the players or project partners are affected. On the one hand, tokens, badges and vouchers earned and, on the other hand, the accounting modalities. All other data, such as the description of the potential heat sources, are saved in a conventional database, which is continuously backed up. Transactions on the blockchain, as accessed from the graphical interface of the main account full-node as well as a triggered badge are displayed in figure 2.

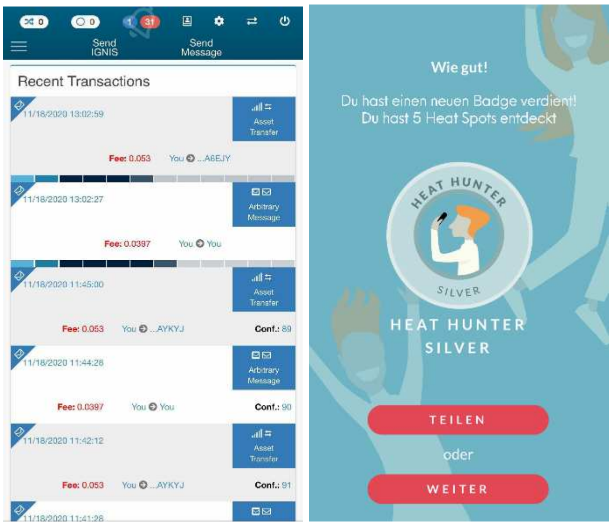

Fig. 2: Blockchain token transaction& visualisation of a triggered badge

4 HOTCITY FIELD TEST

The field test took place in two different phases during the winter 2020/2021. The first phase was performed in November 2020, while the second phase was launched mid of February 2021 for 2-3 weeks. For a part of the test persons, fees were awarded for at least 5-8 hours playing time. All participants received a briefing in advance in the form of a tutorial on the app and in the form of marked districts that showed a high potential in terms of waste heat sources. The responses were collected in anonymous form with a request for open

[8] PWA = Progressive Web Apps are web applications based on modern web browser standardswith additional features for desktop and mobile similar to mobile apps (e.g. notification system). Users can therefore put those web apps to the home screen of their smartphones. https://en.wikipedia.org/wiki/Progressive_web_application

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

critical feedback. A total of 836 tokens were sent out for a) heat sources, divided into bronze, silver and gold and b) badges.

After a 2-3 week test phases, an online questionnaire was created and submitted using the "Survey Monkey" software. The item collection contained both open and closed questions with dichotomous and rating scaled gradations.A total of 31 people took part in the test and filled out the online questionnaire. The majority of the test persons (almost 68%) tested the app in Vienna, the rest (32%) in Graz.

4.1 Usability Score & Acceptance Rating

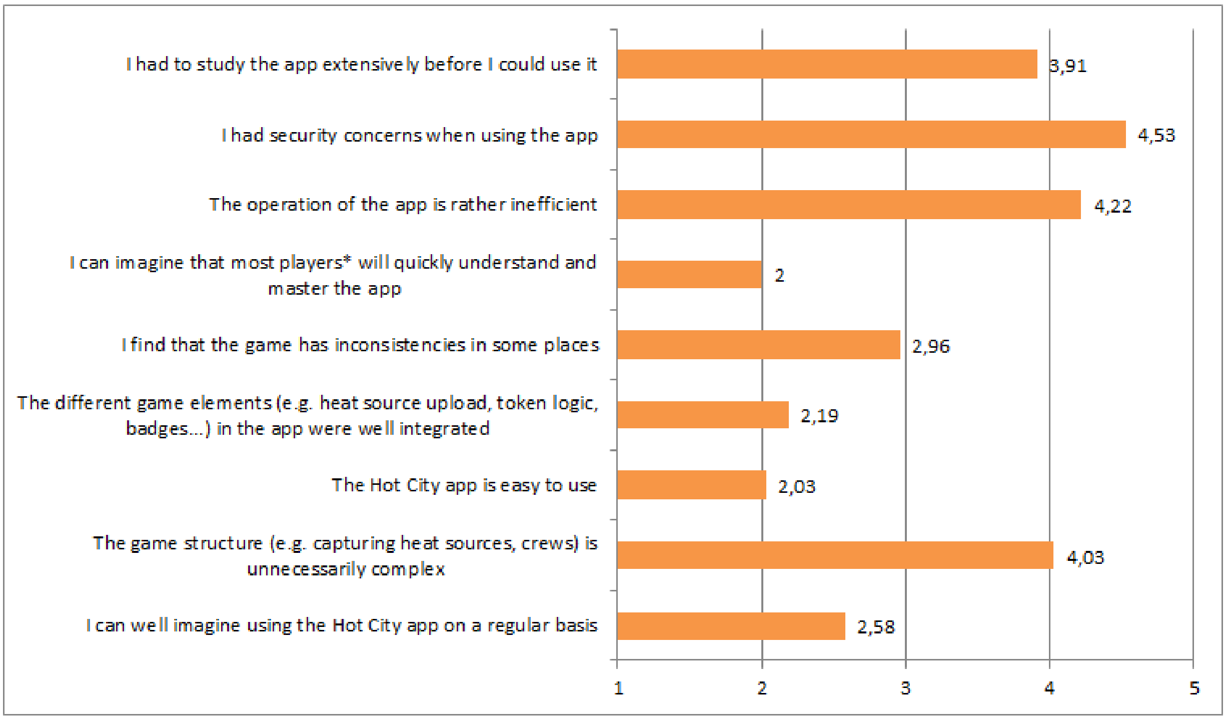

Fig. 3: Usability & Acceptance Score; low values are equal to high levels of agreement

Satisfactory values could be reported with regard to the usability & acceptance of the app. The usability is subjectively high (mean values from 2.0 to 2.58). The simple user interface (M=2.0) and the assessment of the comprehensibility for other users (M=2.03) are particularly noteworthy in this regard.

The normalised SUS (system usability scale) score is 79.675, which corresponds to an above average value (maximum = 100, minimum = 0).

4.2 App testing lessons learned

The results of the field test show high values for the acceptance of the app. The fun of play and the level of difficulty were also rated as appropriate. The standardised SUS score is in the upper fifth, a high subjective usability is thus evident.

The core functionality of the app - the search for waste heat sources, which was designed and integrated in accordance with the project goals - is seen as motivating by the users; compared to other game features, the entertainment value is particularly high.

With regard to the qualitative aspects, the design of the app, the game idea and the ease of use were praised by the test persons.

Problems were encountered with regard to GPS positioning, which sometimes did not work immediately and had to be corrected manually.[9] In addition, as the first phase of the field test in particular showed, it was sometimes difficult for the users to find suitable heat sources, and chimneys from private households, which are no valid waste heat sources, were often photographed. Through clearer communication and tutorials, this problem was alleviated in the second test phase.

[9] A technical problem here is that automatic GPS positioning reduces the duration of one battery load, thus a compromise has to be chosen, or using manual GPS postioning, which reduces the usability experience.

Suggestions for improvement mainly refer to an improved tutorial (phase I) and an automated location on the map of the potential waste heat sources.

Recommendations:

- Provide an optional tutorial video and a half-hour webinar to introduce and explain the app. As user segmentation in the future could include regular users, experts as well as community experts.Such a webinar is an efficient method for onboarding and providing the necessary skills to assess waste heat sources according to their potential.
- Simplify the registration process by publishing it in the app stores. The current process requires several steps, which cause a time delay for users and thus make "seamless onboarding" difficult. In addition, the release had to be done manually due to restrictive settings on company devices. A release in the app store would prevent such problems.
- Integration of a button to update one's GPS position within the app. This function facilitates correct positioning, and a "double-select" interaction for uploading photos should be introduced so that users can enter or readjust their GPS position correctly.
- Switching the map view to a satellite view. This makes it easier to recognise waste heat sources, and it is also possible to estimate the height of objects/heat sources using Google Earth 3D, for example.
- Integration of notifications for finding heat sources and invitations to groups. This also regularly encourages users to use the app, but a good balance must be struck so as not to exert a disruptive influence.
- The token logic should be adapted so that the confirmation of heat sources is only possible between different groups/crews. The "report" function for uploaded heat sources should be reframed to create a positive connotation and thus encourage use by users.

5 RESULTS

The current results have been established due to two test phases with a very small amount of payed testers, and thus can not enable to elaborate the total waste heat potentials in Vienna and Graz. The 31 test users found about 230 individual spots with a possible waste heat potential, and for about 10% of them, detailed information was collected. It has to be noticed that the test users werepayed for about 5-8 hours of testing including the survey and thus it can be assumed that only very limited time for searching was aquired.

The results have been evaluated on different levels: First the images uploaded by the testers have been checked by waste heat experts within the HotCity project team for validity (is it according to what we are looking for –as explained in the tutorial–,correct classification, correct GPS position). Second, the detailed input data to derive the waste heat potential were also validated by waste heat experts.

5.1 Visualisation and Economic feasibility evaluation of results

The data stored on the backend was accessed via the developed API, pre-processed and filtered to eliminate the waste heat proposals reported by the players, to be most likely wrong.Therefore R-Scripts have been developed which makes it easy to analyse the data after each test run.

5.1.1 Visualisation

A simple web-application was developed to simplify the evaluation process for experts and visualise the collected waste heat proposals by the tester.The following figure shows exemplarily one of these waste heat proposals, a re-cooler on the roof top of a building in Vienna.

5.1.2 Economic feasibility evaluator

Based on a limited amount of input parameters, a simplified economic feasibility calculation of waste heat utilisation is carried out in order to evaluate if the waste heat sources identified by the users can be actually used. Here, the characteristics of the waste heat sourceand possible heat consumers (e.g. nearby buildings) were compared with regard to: energy supply and demand, available and required temperature level (including the requirements for the integration of heat pumps if the source temperature is lower than the consumers temperature), economic factors, a possible pipe routing and substations. The economic evaluation of the utilization of the different waste heat potentials found by the users is done on the basis of the two key figures "profitability" and "payback time" and is indicated in the form of a "profitability score".

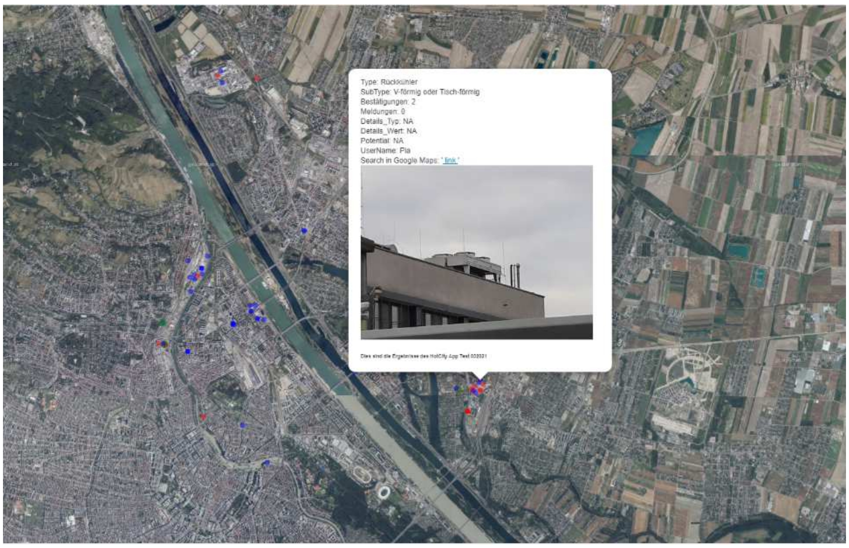

Fig. 4: Waste heat proposals result visualisation web-application screenshot

The results are displayed with help of "economic efficiency scores" i.e. a traffic light system (green, yellow, red), a comparison with a reference system for providing the heating service (e.g. gas boiler) is possible. It should be noted that these estimates are based on partly idealised assumptions. Nevertheless, the results indicatesif an economic use of waste heat sources seems to be realistic.

The developed method was implemened with R-Shiny[10] into an interactive web-application enabling users to evaluate, by chooosing the location and pathway, where the waste heat source would be needed. The following example shows the application (left side) as well as an example of evaluationfor a choosen pathway (right side).

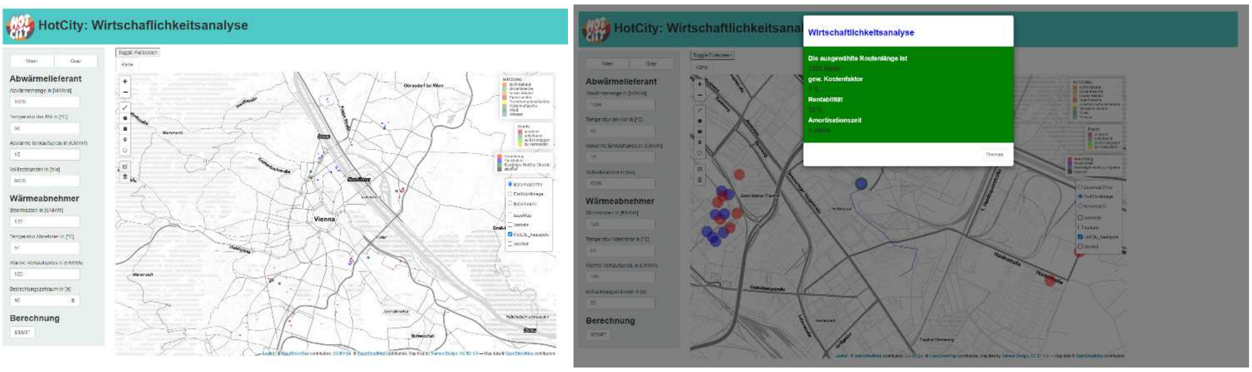

Fig. 5: Screenshots of the Economic feasibility evaluator web-application

6 CONCLUSION AND OUTLOOK

Gamification can be a promising way to identify urban energy data such as waste heat. The reward system could be secured in a transparent way using the energy-efficient proof of stake blockchain Ardor. The HotCity App has been sucessfully developed and tested in two Austrian cities. The two test phases have shown that the app seems to be very promising from a user point of view as the usability score shows. The lessons learned from the two test phases demonstrate that a good briefing (tutorial material) is important to gain useful results within the respective context. Compared to the already existing waste heat data for Vienna and Graz new promising waste heat proposals could be found, which have not been in the data sets so far and for some existing data sets an increased accuracy of the GPS position could be established thanks to the crowdsourcing approach. Interestingly even with the relatively low amout of testers a significant number of valid waste heat proposals could be found. However the tests also helped us to identify potential obstacles especially regarding details attached to heat spot entries which can be used for estimating the amount of

[10] https://shiny.rstudio.com/

waste heat for each waste heat proposal. The results indicate that these are hard to collect with the current app, thus more advanced users (experts) or higher incentives are needed to collect this information. The developed interactive evaluation tool (web-application) seems to be a very good starting point for experts (not necessarily players) in order to filter the most promising waste heat proposals and to estimate their actual potential.

6.1 Further data collection possibilities

The HotCity project aimed for a proof of concept if gamification is a valid method to collect useful spatial energy data in an efficient way, waste heat was only one example for this the following section discusses other possible use cases for the Game/App. The project also investigated conceptually which data and which methods are needed to collect energy-relevant data by means of gamification. In the project, the focus is basically on the topic of determining waste heat potential. However, in order to make more general statements about which energy-relevant data can be collected over-all via crowd-based methods, further data and possible sources were analysed.

The following core questions were addressed:

- How can the game be generalised and used to collect a wide range of energy-relevant data and applications?
- What data can be collected?
- How can the effort for the players on the one hand, and for the software developers with the greatest possible benefit be reduced?

When comparing the results from the players' point of view with the software developers' point of view, it is noticeable that the data that is easy to collect for players is quite difficult to implement for the software developers. For many of the data sets to be collected, the players can upload photos in the app, which is possible without much effort. The photo provided shouldthen be analysed using automated methods in order to derive energy-relevant data from it. Algorithms for image recognition should be applied or developed, which considerably increases the effort for the (software) developers.

The method of "self-assessment" is again time-consuming for players or only possible with expert knowledge anyway; on the programming side, this is implemented through forms so that the findings can be entered as free text or by means of guided questions.

In the course of the app development, a way was found to keep the complexity of the app as low as possible for the players, but still to design the functionalities for data collection and to choose the features of the app in such a way that the programming effort remains justifiable.

The gained results and the additional use cases discussed above vote for a further development of the prototype, especially as it seems that many of these still open issues can be solved with relative low effort and the applicability in different regions and contexts are high.

1 ABSTRACT

The COVID-19 pandemic fuelled the trend of linking online consumption to local interests (such as buying local or localising production). In Austria, the pandemic fostered local eCommerce platforms offering local goods or goods from local retailers. This concept of local digitalism (Fuentes-Bautista, 2011) focuses on the spatial aspects of consumption and production. However, it is difficult for local eCommerce platforms to achieve sufficient online traffic next to internationally established eCommerce platforms. Therefore, evidence-based knowledge on essential customer-centred functions of eCommerce platforms supporting local retail is required. In this study, we screen a sample of local eCommerce platforms in Austria (n=40) and derive a list of customer-centred functions resulting in more than 100 customer-centred functions. A revision procedure with local retail experts helps to condense and categorise the listed functions. Based on a typology adaptation of Standing, Standing & Love (2010) and Bakos (1998), the functions ultimately comprise six categories: (1) performance parameters (i.e., all functions indicating platform performance such as website traffic, mobile optimised implementation, app availability, platform reach and types of products and services offered on the platform, (2) information and connection (i.e., all functions supporting information retrieval on the platform, its vendors and products as well as product search and product filtering), (3) matching (i.e., all functions enabling the matching process between buyer and seller after product selection), (4) customizability (i.e., all settings on the platform to be individually changed by the customer), (5) transaction and fulfilment (i.e., all functions enabling the transaction process and fulfilment services for product purchase and delivery), and (6) sustainability (e.g., information on product materials, product origin, product delivery, or quality seals).

Subsequently, independent platform visitors analyse the platform sample (n=40) using the consolidated list of customer-centred functions and a binary coding scheme (0 = function not available on the platform, 1 = function available on the platform). This evaluation results in customer-centred perception matrices for each local eCommerce platform. Based on the matrices, we derive the overall implementation degree for every customer-centred function. Also, we conduct Fisher's exact test to determine whether there is a significant association between website traffic and function range. Out of the long list of customer-centred functions, we finally extract and discuss the most relevant customer-centred functions for local eCommerce platforms.

Keywords: COVID-19 pandemic, local retail, local eCommerce platforms, customer-centred functions, online consumption

2 INTRODUCTION

On large international eCommerce platforms, such as Amazon or eBay, the boundaries between business-to-business (B2B) and business-to-consumer (B2C) are blurring and regional, national, or international barriers tend to disappear (Pan, Shankar & Ratchford, 2002). With the emergence of local eCommerce platforms, a countervailing trend of platforms bringing the location back into the focus of their business models is becoming visible. Local eCommerce platforms sell the existing range of goods from local shops through their platform and try to gain time advantages in delivery by having the participating local shops act as decentralised shops for households in the neighbourhood (Wirtz et al., 2019). On the one hand, this approach seems promising as it supports local shops in their digital transformation and in overcoming to participate in eCommerce (Stockdale&Standing, 2004 and Sandberg& Håkansson, 2014). On the other hand, challenges arise in getting local retail to cooperate and use shared services between competitors. Studies show that local retail businesses, like other small and medium-sized enterprises, are still hesitant to adopt eCommerce channels (Bollweg et al., 2020 and Pantano&Viassone, 2014) or participate in existing international eCommerce platforms. Thus, the phenomenon of the hesitant digital transformation of local retail businesses is linked to numerous internal (e.g. financial circumstances, lack of knowledge) and external (e.g. lack of standards, lack of subsidisation, lack of marketing) framework conditions (adoption barriers). For local eCommerce platforms to be competitive next to internationally established eCommerce platforms, evidence-based knowledge about the most relevant customer-centred functions on such platforms is crucial.

3 METHODOLOGY

This study identifies relevant customer-centred functions for local eCommerce platforms. As shown in other studies (Radziszewska, 2018 or Jhingran, 2000), local eCommerce platforms are not exclusively those offering product purchase and fulfilment, but also product finders, store finders, and social media channels. Thus, we define four different types of local eCommerce platforms in the first step. With the help of an explorative web search and expert suggestions from the Austrian Retail Association, we compile a manifold sample of eCommerce platforms for each platform type. General eCommerce platforms and, in particular, those with a focus on local retail are taken into account. The sample includes international and Austrian eCommerce platforms (n=40). Visiting and screening the platforms results in a long list of customer-centred functions. An expert talk with participants from the economy, local retail, and science leads to a final and content-evaluated list of customer-centred functions.

Additionally, we define and collect performance values for each platform (i.e. website traffic, page loading time, app availability, mobile optimised implementation). Subsequently, four independent coders visit and assess each platform using the list of customer-centred functions and a binary coding scheme (0 = function is not implemented, 1 = function is implemented). As a result, four independent assessment matrices are available for each platform. The assessment matrices enable the degree of implementation and perceptual values for each function and platform type. We conduct Fisher's Exact Test (Li, 2014) to describe a possible relationship between function range and website traffic. Out of the long list of customer-centred functions, we finally extract and discuss the most relevant customer-centred functions for local eCommerce platforms.

4 LOCAL E-COMMERCE PLATFORMS: THE SAMPLE

Based on a typology adaptation of Nickerson (2002), Bärsch et al. (2019) and Hübner et al. (2020), we define four types of local eCommerce platforms: marketplaces, product finders, store finders, and social media channels. Marketplaces provide full functionality from product search to transaction and fulfilment, whereas product finders and store finders help users find or locate a product or store. Respectively, product finders and store finders require less functionality than marketplaces but can potentially foster the local aspect of product search. Social media channels play a specific role when it comes to trendsetting, influencing, and product choice. Ideally, social media channels promote local stores through advertisements and product promotions (Ravi&Joel, 2019). In this study, social media channels are a substantial part of eCommerce but will not be assessed regarding their functionalities. The compiled platform sample considers international and Austrian eCommerce platforms, general eCommerce platforms and eCommerce platforms focusing on local retail. The sample consists of 24 marketplaces, 13 product finders, and three store finders.

5 CUSTOMER-CENTRED FUNCTIONS FOR LOCAL E-COMMERCE PLATFORMS

The functions implemented on local eCommerce platforms are not uniformly structured and differ significantly in their range. By screening the platform sample, we create a list of customer-centred functions for each platform type. Customer centred-functions are analysed and discussed in Bärsch et al. (2019) and Hwang& Preiser-Houy (2012). In this study, the list of customer-centred functions is based on Bärsch et al. (2019) in its structure but offers a broader range of functionalities.

Information and Connection: This category comprises all functions supporting information retrieval on the platform, its vendors and products, and the product search and product filter process. Customer support (i.e., all functions enabling the customer to contact the platform operators or retailers) and platform reviews are part of this category.

Matching: Matching refers to all functions enabling the matching process between buyer and seller after product selection. The category includes detailed product information, product comparison (regarding price, payment options, duration of delivery), product reviews, store or retailer reviews, and loyalty programme (such as free delivery or special offers).

Customizability: Customisable functions can be changed individually (i.e. registration, account settings and privacy cockpit).

Transaction and Fulfilment: Transaction and fulfillment refer to all functions enabling the transaction and fulfilment services for product purchase and delivery. The category comprises payment options, delivery options, and return options.

Sustainability: This category checks whether the platform provides sustainability information on the platform itself, the products, or the delivery process (e.g., information on product materials, product origin, product delivery, or quality seals). Table 2 represents the categorisation scheme for the identified customer-centred functions.

Performance Parameters	**Information and Connection**	**Matching**	**Customizability**	**Transaction and Fulfilment**	**Sustainability**
Type of platform Platform performance Platform reach Types of offers	Transparency & Trust Customer support Product search and product filter Platform reviews	Product details Product comparison Product reviews Store or retailer reviews Loyalty programme	Registration Account settings Privacy cockpits	Payment options Delivery options Return options	Sustainability information – platform Sustainability information – products Sustainability information – delivery

Table 2: Categorisation scheme for customer-centred functions

In total, we create a list of 103 customer-centred functions. The functions are not always equally relevant for each marketplace type, so marketplaces are assigned 103 functions, product finders 72 functions and store finders 68 functions.

6 PLATFORM ASSESSMENT: RESULTS

Four independent coders visit each platform and use a binary coding scheme to check whether the listed function is implemented on the platform or not (0= function not implemented on the platform, 1=function implemented on the platform). The assessment matrices enable the degree of implementation to be determined for each function and platform type (table 3 to table 8).

6.1 Implementation degrees

PLATFORM PERFORMANCE	**Marketplaces** n=24	**Product finders** n=13	**Store finders** n=3
Platform performance			
Website traffic indicated	45,83	30,77	33,33
Available as an app	37,50	23,08	33,33

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Website traffic is an important performance indicator for eCommerce platform evaluation (Singh &Kumari, 2019). In this study, we use open-source software to identify website traffic on each platform. This measurement goes along with limitations as the tool can only report very high website traffic. Thus, for platforms with low website traffic, no data is collected. In our sample, 11 out of 24 marketplaces show high website traffic (45,83 per cent). Website traffic on the recorded marketplaces ranges from 164.650 to 498.730.000 monthly visits. Website traffic on recorded product finders ranges from 344.210 to 21.870.000 monthly visits.

Regarding store finders, one platform out of three shows website traffic of 144.960 monthly visits. All examined platforms are implemented for mobile use. When it comes to app availability, 9 out of 24 marketplaces are available as an app (37,50 per cent), 3 out of 13 product finders (23,08 per cent) and 1 out of 3 store finders (33,33 per cent).

Table 4: Implementation degrees [%] within the category "Information and Connection". NR indicates that the function is not a required function for the respective platform type.

On average, marketplaces implement 14 out of 31 functions (45,16 per cent) within the category "Information and Connection". Product finders average 11 out of 28 functions (39,29 per cent), and store finders 7 out of 27 functions (25,93 per cent). Transparency and trust play a significant role in building a trusted relationship between customer and platform. Indicating the payment, delivery and return options directly on the desktop is essential information for the platform visitor. For marketplaces, a Q&A rubric on the platform is an essential function for customer support. This function is not yet implemented on all marketplaces. Functions for product search and product filter differ in their implementation degrees. Filter functions for payment and delivery options are missing. Customer-generated content (CGC) can help platform operators to improve the platform successively. Review options for the platform itself as well as for products and retailers help to identify gaps and existing problems. Not only for platform review but also product and retailer review, the implementation degrees are low.

Table 5: Implementation degrees [%] within the category "Matching". NR indicates that the function is not a required function for the respective platform type.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

On average, marketplaces implement 13 out of 29 matching functions (44,83 per cent). Product finders implement 10 out of 27 matching functions (37,04 per cent) and store finders 2 out of 27 matching functions (7,41 per cent). For product details and specifications, the integration of social media inspiration has not yet been implemented on any of the analysed platforms. Also, the digital availability of documents such as manuals has not yet been implemented on any of the platforms. Regarding product comparison, the indication of delivery duration at different retailers shows a low implementation degree. Product reviews show a higher implementation degree than retailer reviews, and stars occur more often than comments as review elements. Regardless of whether reviews are made publicly visible, the opportunity to give feedback on the platform, the product, the retailer, and the delivery are an essential element to successively improve the platform implementation and the processes along the customer journey. Marketplaces implement loyalty programmes in the form of vouchers to 90 per cent. Other customer retention strategies (such as customer card, personalisation options, special offers when subscribing to the newsletter) are implemented up to 87,50 per cent.

Table 6: Implementation degrees [%] within the category "Customizability". NR indicates that the function is not a required function for the respective platform type.

Marketplaces average 7 out of 20 customisable functions (35,00 per cent). Product finders implement 2 out of 13 customisable functions on average (15,38 per cent) and store finders 1 out of 10 customisable functions (10 per cent). Personalisation options show low implementation degrees regarding the specification of a preferred product origin, delivery preferences, and recurring orders. Importing an existing digital ID (for example, from another platform) and avatar creation seem to be relatively rarely implemented functions. The same result applies to storing product-specific documents, such as warranties or invoices, within the private account.

TRANSACTION AND FULFILMENT	**Marketplace (n=24)** **18 functions**	**Product finder (n=13)** **0 functions**	**Store finder (n=3)** **0 functions**

Table 8: Implementation degrees [%] within the category "Sustainability". NR indicates that the function is not a required function for the respective platform type.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

On average, marketplaces implement 1 out of 5 sustainability functions, and product finders and store finders do not implement sustainability functions.

6.2 Fisher's Exact Test

To examine whether there exists a significant relationship between website traffic and function range, we perform Fisher's exact test. Table 9 shows the distribution of website traffic and function range for marketplaces. The average function range for marketplaces is 42 out of 103 functions. Thus, Marketplaces with more than 42 functions are assigned a high functionality range. Fisher's exact test will indicate whether the sown distribution between function range and website traffic is subject to randomness.

Marketplaces	Low website traffic	High website traffic	Total
Low functionality range (<42)	9	0	9
High functionality range (>42)	4	11	15
Total	13	11	24

Table 9: Distribution of website traffic and function range for marketplaces

The table suggests that marketplaces with a high function range are more likely to have high website traffic. The null hypothesis for Fisher's Exact Test states that website traffic and function range are independent. The two-sided p-value for this distribution results in .001, leading to a rejection of the null hypothesis. Thus, we have evidence that there is a significant association between website traffic and the function range of marketplaces. The effect size (phi coefficient) is .713, indicating a strong positive association between the variables.

6.3 Making the difference: Functions emphasising the local aspect

Completing a comprehensive list of customer-centred functions for local eCommerce platforms enables the definition of functions that particularly emphasise the local aspects of product and store search. Table 10 illustrates relevant functions for the enforcement of local retail on eCommerce platforms.

Information and Connection	**Matching**	**Transaction and Fulfilment**	**Sustainability**
Transparency and Trust	Product details	Delivery	Product
Payment information – desktop	Product location on a map	Same-day delivery	Indication of product origin
Delivery information – desktop	Availability of product in local store	Pick-up stations	
Return information – desktop	Information and location on local retailer on the map	Collect product directly in the shop (click&collect)	
	Contact information of the local retailer		
Product search and filter	Product comparison	Return management	
Availability of product in local store	Availability of the product at other local retailers within a specific distance band	Return or change product directly in the shop	
Spatial proximity of the product to the current location of the user	Loyalty programme		
Possibility to filter products by local store/retailer	Possibility to directly contact the local retailer regarding product questions		
Possibility to filter products by current location, region, province	Possibility to have a product repaired in a local store		

Table 10: Relevant functions for the enforcement of local eCommerce platforms

Seven functions within the category "Information and Connection" have relevance to strengthen local retail: payment information (desktop), delivery information (desktop), return information (desktop), availability in a local store, product distance from current location, selection of local retailer, product selection by current positions, region, or province. As the implementation degrees for these functions show, there is a particular need for action in implementing spatial components such as visualising the product location on a map or indicating the distance of the product from the user's current location.

Also, ways to contact local retailers or to pick up and change local products directly at local retailers are relevant when implementing local eCommerce platforms. Thus, a direct contact link to the local retailer should always be available.

Regarding product comparison, the availability of products at other local retailers, the comparison based on the spatial proximity of the product to the current location of the user and the differences in duration of delivery at different retailers show low implementation degrees.

Relevant functions regarding local eCommerce platforms within the category "Transaction and Fulfillment" are same-day delivery, pick-up stations, collection of good directly in the shop and return and change of good directly. These functions are implemented in less than 50,00 per cent of the examined platforms but can make local eCommerce platforms stand out from established international eCommerce platforms.

The designation of product origin (e.g., regional products) and the resulting traceability of, for example, regional products can be regarded as a vital function to be implemented in local eCommerce platforms.

7 LIMITATIONS

Certain limitations must be taken into account when interpreting the results of this study. First, the platform sample includes a country-specific bias as the platform sample primarily consists of Austrian eCommerce platforms. International platforms are included as a counterpart to the Austrian platforms. Therefore, future studies should consider the integration of other international platforms. As for calculating the implementation degree of the customer-centred functions, an optimistic procedure is applied: implementation degree for each function results from the analysis of four independent coders. If one coder rates a function as 1 (=implemented) and the other three coders rate it as 0 (=not implemented), the function is still reported as implemented. Therefore, the follow-up study needs to intersect implementation levels with perception values.

8 CONCLUSION

This study outlines that, as with eCommerce platforms, the implemented customer-centred functions are not standardised and strongly differ. Thus, the study suggests a thematic scheme to structure customer-centred functions and assign them to different eCommerce platforms. The analysis of 40 different eCommerce platforms indicates the potential for local eCommerce marketplaces to integrate specific location-related functions. Fostering the implementation of location-related functions can be regarded as a significant issue to make local eCommerce platforms more competitive next to internationally established eCommerce platforms. The study also indicates a significant relationship between function range and website traffic, which we will further explore. Also, the study's results provide the basis for a subsequent priority assessment of customer-centred functions for local eCommerce platforms by blending implementation degrees with perception values.

1 ABSTRACT

Climate change is reshaping societies. As we see more and more people moving to urban areas an ever-increasing number settles in low-cost and more hazardous areas. However, due to the rapid growth and sheer scale of informal settlements, knowledge gaps often exist on location or quantity. In this sense, Earth Observation combined with machine learning techniques allows to generate reliable geo-information. In this study, we classify the morphologically heterogeneous entire urban area of Medellín, Colombia into urban structural types. We do this by the Local Climate Zone (LCZ) scheme. Our specific focus is on one structural type, i.e. informal settlements. We test whether it is feasible by the LCZ concept to localize and quantify these vulnerable areas. The LCZ scheme is generic, replicable, neutral, and has become widespread in urban studies. We use urban blocks to perform a scene-based image classification into nine LCZs. We refer to multi-modal remotely-sensed data: high-resolution multispectral image data and elevation data. We apply an optimized random forest algorithm using shape metrics, as well as spectral and texture features. In general, we find the LCZ classification, measured with an overall accuracy of 82%, shows a reliable representation of urban typologies and functions across the city. Specifically, we compare the urban blocks classified as the LCZ lightweigth low-rise to the informal settlements provided by the city of Medellín. Here we reach an agreement of 86%. Besides, our approach complements the official dataset by including recently developed areas which are not yet considered by the city.

Keywords: Earth Observation, Machine Learning, Informal Settlements, Random Forest, Local Climate Zone

2 INTRODUCTION

Climate change and upgrading living conditions are two well known push and pull factors of the rural-urban movement and migration between countries. Urban areas are now home to the majority of the world's population and are expected to record a continuous flow of migrants (UN, 2019). Cities have a higher economic growth, more opportunities, better access to education, health, employment, and in general, many services that makes moving to a city seem attractive (Glaeser, 2011). But it can also be disadvantageous, since cities are more unequal than rural areas, i.e. wealth coexists with severe deprivation (UN, 2020). Besides, climate change displaces people due to a higher frequency of natural hazards like wildfires, storms, or droughts, and making some places less livable and productive, which results in an ever-increasing number of people migrating to cities (Adger et al., 2020).

The Sustainable Development Goals (SDGs), set by the United Nations in 2015, pursue a sustainable future for people and the planet by ending poverty and addressing social needs, while protecting the environment and fighting climate change (UN, 2015a). Cities as a habitat for more than half of the world's population are crucial for the successful implementation. Thus, the functioning and evolution of urban systems have been in the spotlight for planners, policymakers and researchers (e.g. Lobo et al., 2020; Oliveira, 2016), and several studies have been conducted in this regard. For instance, the impact of the morphology and functions of a city on many different factors, such as heat distribution and ventilation performance (e.g. Zhao et al., 2020; Jin et al., 2018a), air and noise pollution (e.g. Han et al., 2018; Edussuriya et al., 2014), or resilience in case of natural hazards (e.g. León & March, 2014). Moreover, a recent study evidenced that spatial structure in cities is indeed related to the quality of life and sustainability, the configuration of urban structural types within cities is linked to socio-economic functions (Sapena et al., 2021).

Within the urban conglomerate informal settlements are underdeprived neighborhoods, which lack basic services (UN, 2015b) and are often located in low-cost and more hazardous areas of the city as a result of low urban planning capacities and failing formal land markets. Especially in the Global South they are part of the persistent contemporary urbanization process (Stark et al., 2020; Kuffer et al., 2016; Lall & Deichmann, 2012) and even though they often represent a large proportion of the population, there is a general lack of understanding about their role within the city (Patel & Baptist, 2012). Besides, due to their high dynamic and rapid growth rates (Kraff et al., 2020), frequent monitoring in near real-time and high resolution data is necessary (Mahabir et al., 2018) in order to produce valuable information for governance, risk assessment studies, etc. (e.g. Wurm et al., 2019; Kuffer et al., 2018).

Earth observation (EO) enables the creation of up-to-date, consistent and extensive information on urban environments with a high degree of objectivity, transferability and automation (Voltersen et al., 2014). The characterization of large-scale urban morphology relies on remote sensing data and methods. Depending on available satellite images and objectives, different classification methods, e.g. parametric/nonparametric supervised/unsupervised, pixel-/object-/scene-based (Tsoeleng et al., 2020; Liu et al., 2017; Phiri & Morgenroth, 2017; Zhang & Du, 2015), can be used to classify the urban land cover. However, regarding informal settlements, their intra- and interurban variability makes their identification sometimes difficult (Stark et al., 2020; Taubenböck et al., 2018; Kuffer et al., 2016).

Image classification into land use types is an important source of information for urban studies, however, it often lacks three-dimensional information (Wentz et al., 2018). Therefore, the characterization of cities into urban structural types and land cover with the Local Climate Zone (LCZ) classification scheme (Stewart & Oke, 2012) produces high-level semantic data by adding information on urban form and function to traditional land use legends and it has great potential that is worth exploring. LCZs represent the strcutural appearance of cities in a conceptually consistent manner, is intuitive and replicable. The classification scheme comprises ten built-up structural types and seven natural land cover types with uniform surface cover, structure, material, as well as human acitivity, having inherent information on the physical composition of cities, by their density, building types, heights, greenness, and land cover (Taubenböck et al., 2020; Bechtel et al., 2015; Stewart & Oke, 2012). Even though LCZ were originally created for urban temperature studies, now the concept is becoming popular in many other research areas. Some examples are: urban planning, risk assessement, building energy consumption or human health, to name a few (Xue et al., 2020).

With this background, in this study we aim to physically characterize the complex urban agglomeration of the city of Medellín, Colombia. We specifically focus on the identification of informal settlements using high-resolution EO data and additional geospatial datasets based on machine learning techniques. In doing so, we test the suitability of the LCZ concept to locate and quantify informal settlements.

3 MATERIAL AND METHODS

In this section we introduce the study area, describe the datasets used as well as their pre-processing steps and explain the methodology and validation proposed for the classification of urban structural types using EO data.

3.1 Study area

Medellín is the second largest city in Colombia, the capital of the Department of Antioquia and of the Metropolitan region of the Aburrá Valley. The latter forms a political and administrative unit of ten municipalities (Garcia Ferrari et al., 2018). The municipality of Medellín had around 2.4 million inhabitants in 2018 (DANE, 2018). Our area of interest (AOI) is represented by urban and expansion areas, as well as the urbanizing regions outside of the official urban border (Fig.1). Urban expansion areas are in the process of being added into the administrative urban border within the current planning period (2014 – 2027), but are not yet fully included (Alcaldía des Medellín, 2014 a, b), while urbanized areas are defined in this study as the regions at the border of the city, which are urban but not yet included in the official urban and expansion areas, characterized mostly by informal settlements in the official rural part of the city (Fig.1, in blue).

3.2 Data

This section introduces the data used for the classification into urban structural types (detailed methodological explanation in 3.3.1) and for the validation of identified informal settlements (detailed methodological explanation in 3.3.2).

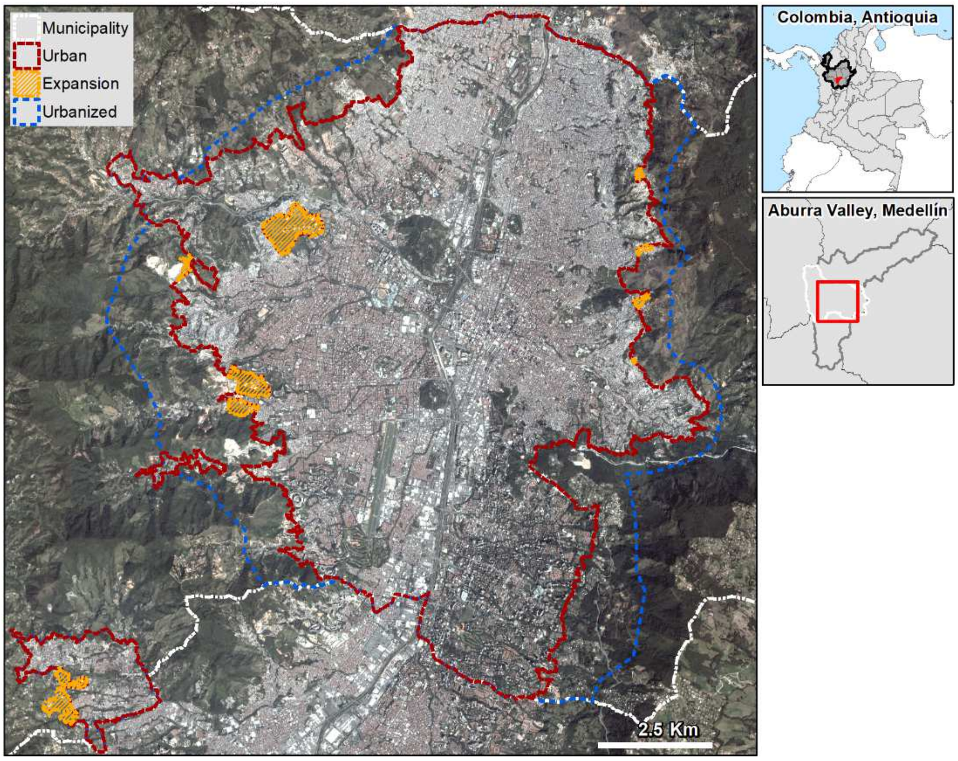

Fig. 1: Location of the study area: Urban, expansion and urbanized areas in the Municipality of Medellín within the Aburrá valley in Colombia. A PlanetScope image is used as background (Planet Team, 2019).

3.2.1 Input data and pre-processing steps

The first objective of this study is to classify Medellín into urban structural types with the LCZ concept. Therefore, we combine satellite data, elevation data, and open administrative geo-information. First, we use high-resolution image data (3m/pixel) from the PlanetScope constellation (approximately 130 satellites) launched in November 2018 and scanning the earth's surface every day, providing scenes with four spectral bands: red, green, blue and near infrared (RGB NIR; Planet Labs Inc. 2021). We acquire 13 scenes with 0% cloud coverage from the 1st of January 2019 to build one image mosaic covering the Aburrá valley (Table 1). By combining the different bands, we initially calculate the Normalized Difference Vegetation Index (NDVI), a spectral index showing the normalized difference between the red and infrared bands and providing spectral information on vegetation greenness (Rouse et al., 1973). This index has been widely used in land-use/land-cover (LULC) classifications to improve the performance of the classifier (Weigand et al., 2020; Jin et al., 2018b). Thereafter, we calculate the Grey Level Co-occurrence Matrix (GLCM) for each visible band (RGB), a method proposed by Haralick et al. (1973), and we extract eight textural features: mean, variance, homogeneity, contrast, dissimilarity, entropy, second moment and correlation. The use of texture improves classification results since it mitigates confusion between spectrally similar classes (Li et al., 2014a; Vadakkenveettil et al., 2012). Secondly, we use an open digital elevation model (DEM) from the year 2019 covering the Aburrá valley with a spatial resolution of 10m that provides the height for each pixel (Table 1). The DEM is utilized to calculate the slope for each pixel, used as additional feature in the classification. Thirdly, we use the boundaries of the urban blocks from the administrative planning department of Medellín (Table 1) as polygons to perform a scene-based image classification into the urban structural types (see section 3.3). Compared to the spatial units of pixels and objects, scenes as a collection of different objects have the ability to provide high-level semantic information on urban functions, land use patterns and environmental issues, additional to LULC information (Liu et al., 2017; Zhang & Du, 2015). For each polygon from the urban blocks (i.e. scenes), we compute two well-known shape metrics: the compactness and shape index. The former indicates the compactness of a polygon, and the latter gives information on the overall shape complexity, both are calculated following the formulas by Jiao et al. (2012). Finally, we combine the four spectral bands, the NDVI, the twenty-four texture features (eight per band) and the slope with the urban blocks for the scene-based image analysis. We use the polygons as spatial reference to extract ten statistics for each scene: the mean, median, standard deviation, minimum, maximum, range,

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

variance, minority, majority and variety. To summarize, each scene stores 302 features composed by 50 spectral, 240 textural, 10 topographical and two shape metrics.

3.2.2 Informal settlements reference data

The second objective of this study is testing the ability of remote sensing to identify the specific structural type of informal settlements using the LCZ scheme. As reference data for the validation we use the Land Use Treatments (Table 1) from the official Land Use and Zoning Plan 2014 (Plan de Ordenamiento Territorial, POT) published by the city of Medellín. The POT 2014 defines the economic, environmental, urban, and social future of the city from 2014 till 2027. The treatments are homogeneous morphological areas that have different management strategies. For the validation we use two specific treatments: Comprehensive improvement (Mejoramiento Integral, MI) and Consolidation level 3 (Consolidación Nivel 3, CN3). The former are areas of incomplete and inadequate development, located on the edges of the city with low living conditions due to marginality and socio-spatial segregation, poverty, limited development opportunities and access to essential public services. CN3 areas already show a more stable development trend, but still have a deficit of several indicators like public space and services, or road infrastructure (DAP, 2014). We use the treatments MI and CN3 as a reference data since the city administration considers them as precarious settlements (Alcadía de Medellín ISVIMED, 2019, p.116). In this study this is taken as a proxy for informal settlements since "precariousness" or "precarious settlement" are often used as a characteristic or synonym of informal settlements (e.g. Furtado & Renski, 2021).

Dataset	Description	Resolution	Year	Source
Classification input data				
PlanetScope mosaic	It is a satellite image mosaic with four bands (red, green, blue and near infrared).	3 meters/pixel	2019	(Planet Labs Inc., 2021; Planet Team, 2019)
Elevation	It is a digital elevation model covering the Aburrá valley.	10 meters/pixel	2019	(AMVA, 2019)
Urban blocks	It consists of the lower administrative level and usually covers buildings, green space and pavement.	-	2019	(DAP,2019)
Informal settlements reference data				
Land Use Treatments	They define the objectives of development in the municipality, guide the actions required to achieve the policies and objectives established for the land and occupation model of the territory in the framework of the Land Use and Zoning Plan (POT 2014).	-	2014	(POT, 2014); (DAP, 2014)

Table 1: Description of datasets used for the classification and validation.

3.3 Methodology

In this study we perfom a scene-based LCZ classification by means of the machine learning algorithm Random forest (Breiman, 2001). For the classification we use the LCZ concept adapted to Medellín. Initially, we identify eight built-up LCZ classes in the AOI, as shown in Fig. 2 (1- 8). Moreover, to meet the local conditions, we adapt the standard LCZ scheme: we create a new LCZ consisting of coexisting high-rise, midrise and low-rise compact structures within one urban block (Fig. 2, 9). In a second step, after the classification, we extract and compare the lightweight low-rise LCZ (Fig. 2, 7) against the reference data (section 3.2.2). The lightweight low-rise class represents informal settlements from a morphological perspective. It is defined mainly by lightweight construction materials (bricks, wood and metal) with one to three stories in compact arrangements. The land cover often consists of paved or hard-packed soil and few trees.

3.3.1 Random Forest classification and validation

Random forest (RF) is a supervised and nonparametric ensemble classifier that has been shown to produce high accuracies for LULC classifications (e.g. Weigand et al., 2020). The classifier uses decision trees to apply the class membership by the majority rule. The number of trees must be sufficient to get high accuracies; therefore, we use the default value of 500 (Maxwell et al., 2018). In this study we use the 'randomForest' package in R (https://www.r-project.org/). The RF algorithm relies on ground truth sample data to train the model and validate its performance. The quantity, quality, and representativeness of the sample data is decisive for the accuracy of the classification (Li et al., 2014b). In this study, we manually create 1,120 blocks with ground truth information by means of Google Street View image interpretation. The number of samples per LCZ is determined depending on their representation in the city. The number of samples is shown in Fig. 3 (top right). To measure the accuracy of the RF model we split the sample data into training data (50%) to fit the model and test data (50%) for the validation. However, the splitting into training and test data is done randomly, as well as the generation of the decision trees; therefore, the impact of randomness has to be considered. For this reason, we follow the steps proposed in Weigand et al. (2020) and create 100 different RF models (with different sample splittings and trees), and select the one with the highest Overall Accuracy (OA; Congalton, 1991) measured with the test samples. Then, we calculate the Producer's (PA) and User's accuracies (UA), these statistical measures provide information on the performance of each individual LCZ. We also remove features from our set that lower the accuracy. After quantifying and reporting the accuracies, the best performing model is applied to all urban blocks (in total 10,515) to create the final LCZ classification map.

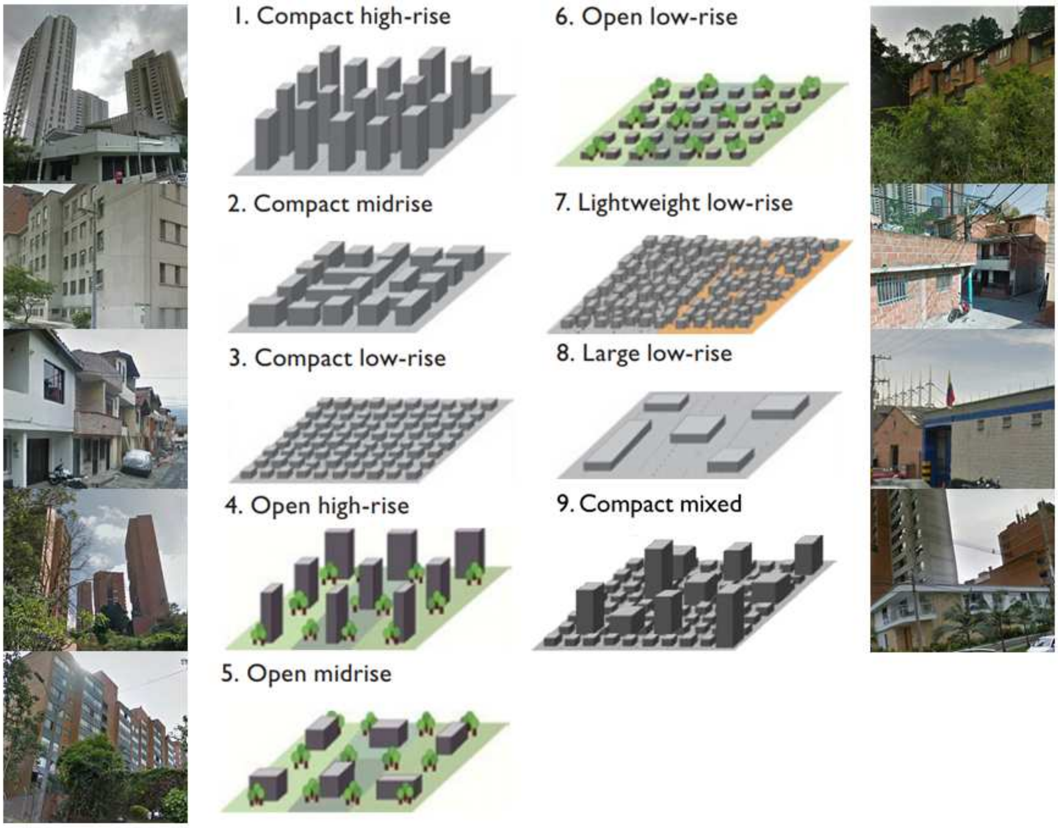

Fig. 2: The nine Local Climate Zones (LCZ) present in our AOI. The photos (from © Google Street View 2021) are examples for the physical expressions of the LCZ classes in our AOI, while the 3D representations are the definitions based on Stewart & Oke (2012).

3.3.2 Evaluation of informal settlement identification

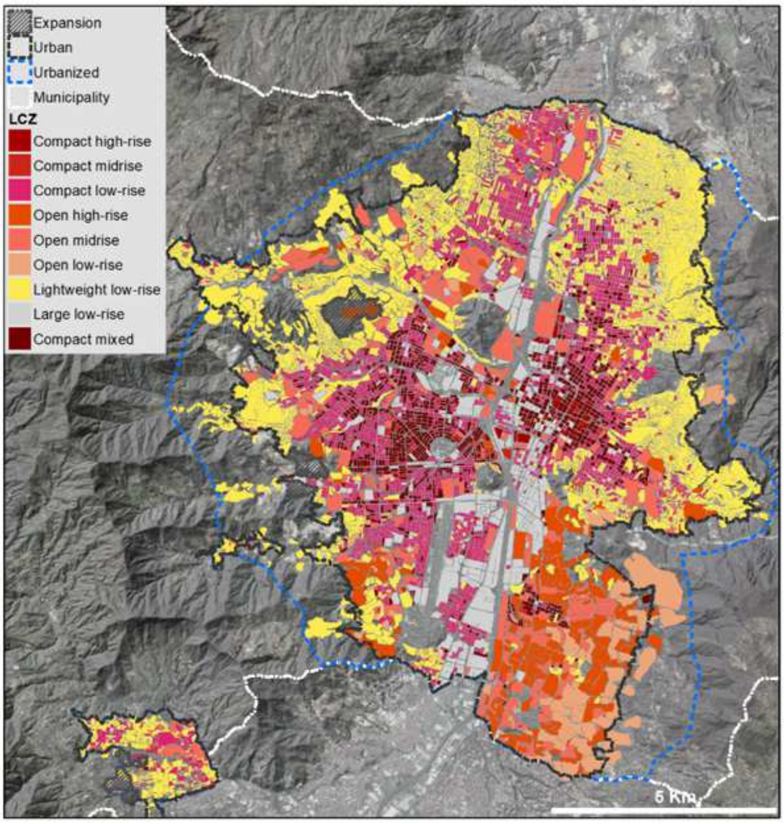
On one hand, we assess the ability of the model to detect informal settlements by means of the UA and PA of the lightweight low-rise (LLR) class. On the other hand, we compare the area and spatial distribution of the LLR urban blocks to the informal settlement reference data. This evaluation is conducted by overlaying the area of the LLR urban blocks with the area of the reference data and deriving the confusion matrix and accuracy statistics.

4 RESULTS

This section explains the results of the accuracy assessment of the LCZ classification and the operability of the LCZ concept to remotely detect informal settlements.

4.1 Classification of LCZs

The classification of the urban blocks into LCZs using the best performing RF model has an OA of 81.9%. The resulting map, shown in Fig. 3 (left), separates the morphology of the city into different urban structural types. The distribution shows a cluster of commercial and production site urban blocks along the Medellín river comprised of large low-rise areas as well as a cluster of compact high-rise, mid-rise and mixed structures in the heart of the city. Open high-/mid- and low-rise structures are predominant in the southeast of the city, where the social status is comparably higher, and LLR areas are located mostly in the (north-)eastern and (north-)western edges of the city in increasingly hilly and steep terrains (Garcia Ferrari et al., 2018). The accuracy assessment for each individual class (Fig. 3, bottom right) shows that more than half of the LCZs have a UA of above 70%, up to 90%, which indicates that only in around 10% to 30% of the cases the classification result deviates from the sample data, i.e. the actual LCZ is different to the predicted class. The PA shows fairly high values for the same LCZs. The highest PA is measured for LLR with over 96%, meaning only 4% of the sample data was underestimated and not classified as LLR. The high UAs for compact high-rise and compact midrise LCZs originate from zero missclassifications, as can be seen in Table 2. But the results have to be interepreted together with their PAs, which are very low. This indicates that a large amount of sample data representing these two LCZs were not correctly classified by the model, which can be interpreted as underclassification. These contradictory accuracies result from the class underrepresentation in the city, and therefore having particularly small sample sizes, making it difficult to distinguish them from other classes. Especially the LCZ compact mixed is classified instead of compact high-rise and midrise (see Table 2). A similar problem occurs for the LCZs open midrise and low-rise. For the UA and PA, having both rather moderate outcomes, Table 2 reveals confusions with other LCZs.



Local Climate Zone	Samples (train/test)
1. Compact high-rise	22 (11/11)
2. Compact midrise	37 (19/18)
3. Compact low-rise	254 (127/127)
4. Open high-rise	56 (28/28)
5. Open midrise	65 (33/32)
6. Open low-rise	57 (29/28)
7. Lightweight low-rise	448 (224/224)
8. Large low-rise	76 (38/38)
9. Compact mixed	105 (53/52)
Total	*1120 (562/558)*

Local Climate Zone	UA	PA
1. Compact high-rise	100%	9.1%
2. Compact midrise	100%	11.1%
3. Compact low-rise	84.2%	88.2%
4. Open high-rise	90.9%	71.4%
5. Open midrise	59.3%	50.0%
6. Open low-rise	75.0%	32.1%
7. Lightweight low-rise	84.8%	96.9%
8. Large low-rise	87.2%	89.5%
9. Compact mixed	69.7%	88.5%
	OA	**81.9%**

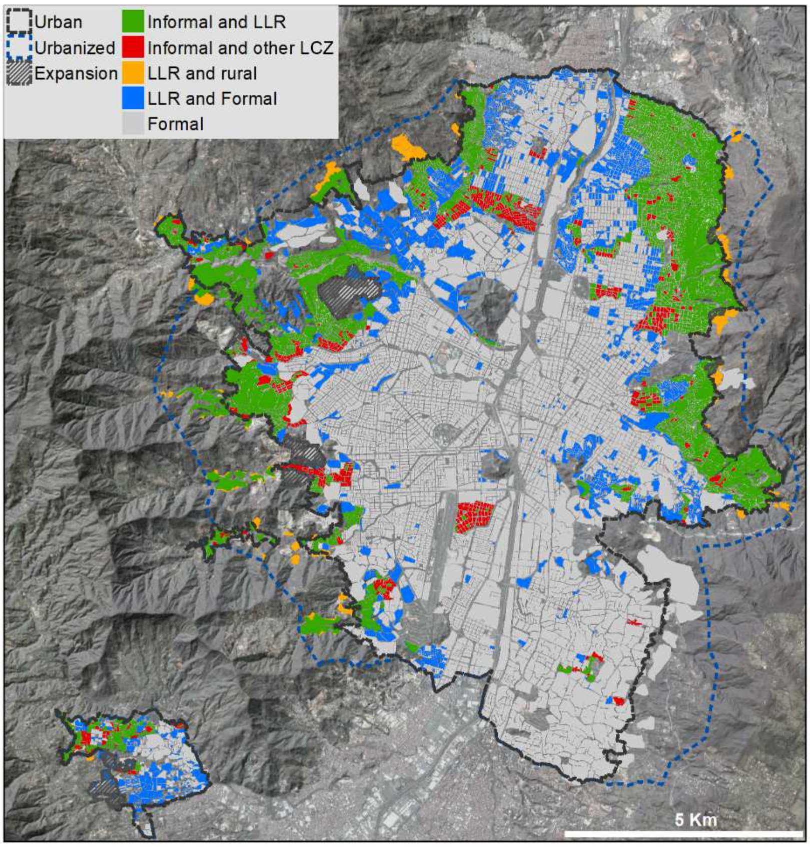
Table 2: Confusion matrix of the best performing model. The test data is used to create the table.

4.2 Comparison between LLR and informal settlements

Results regarding the suitability of the LCZ classification scheme to identify informal settlements show that our method is able to correctly identify 86% of the official delimitation of informal settlements (Fig. 4 in green, PA), and has an underestimation rate of 14% (Fig. 4 in red). From the point of view of the LLR informal settlements, 57% of the identified area corresponds to the official informal settlements (Fig. 4 in green, UA), while 43% are not correctly classified in regards to the reference data, composed of 38% formal and 5% rural areas (Fig. 4 in blue and orange respectively). This shows that even if our method is capable to recognise most of the informal areas in the city, it also overestimates informality that is not officially considered as such even if the morphology and building structures are very similar to other precarious neighborhoods.



Classification LCZ (ha)	Reference data (ha)			
	Informal	Formal	Rural	*Total*
LLR	1638.9	1101.0	153.7	*2893.5*
Other	272.7	4559.3	0.0	*4832.0*
Total	*1911.6*	*5660.3*	*153.7*	*7725.6*

	UA	PA
Informal	57%	86%
Formal	94%	81%

Fig. 4: Left: Overlay of the urban structural type of informal settlements (lightweight low-rise, LLR) extracted from the Local Climate Zone (LCZ) classification with the informal settlements reference data. Right: Confusion matrix in hectares and User's (UA) and Producer's accuracies (PA). The color used in the table shows the same area in hectares that is shown on the map.

5 DISCUSSION AND CONCLUSION

In general, we can state that with our approach - multisensory remote sensing data, machine learning techniques, and the LCZ concept - we are able to derive the complex settlement area in its morphological variability with high accuracy. This means the maps do have a high usability in the panning context. The LCZ classification scheme is standardized and thus shows to be very applicable to Medellin. Nevertheless, due to the special structural situation, we had to add an additional mixed class to the standard wheel in order to be able to adequately describe the urban body. The reached probabilities of a scene to actually represent the LCZ given is considerably high for most of the classes, based on the UA. The PAs are good for most classes as well. The approach proves to be feasible for urban structural types and land cover classification and is therefore an adaptable and good basis for urban analyses. Since the accuracies are affected by the sample count, especially evident for compact high-rise and midrise structures, future applications should consider more ground truth data for these two LCZs if possible, to improve the discrimination between morphologically similar classes. Alternatively, a combination of classes with similar characteristics (compact high-rise, midrise, mixed) might improve the performance of the model, since the confusion between classes will be reduced.

Moreover, this study had a particular interest in assessing the ability of the LCZ classification to identify the specific thematic class of informal settlements based on a morphological foundation. In a broader context, this information is especially relevant for risk assessment, as informal settlements have a higher vulnerability compared to the rest of the city and are often located in low-cost areas and steep slopes with a higher probability of natural hazards (Müller et al., 2020). The LLR class had good accuraccies in the RF model, showing low missclassification rates. Regarding its comparison with reference data, we were able to correctly identify 86% of the reference informal settlements, while the rest is attributed to other LCZs. And even though many urban blocks classified as LLR are officially formal or located in the rural area, our approach using EO data allows to extend the official urban border and include up-to-date information, which let us to identify 154ha of informal settlements that are related to fast and unplanned urbanization in the city edges and thus, are areas not yet officially considered by the city administration. In this case, remote sensing allows to look at the bigger picture and provides a more recent view of informality in the risk-prone hilly areas of the city. Besides, the classification of formal areas as LLR might partly arise from the different underlying conditions between morphological and official informal settlements. For a large part of the scenes classified as LLR, that are officially formal, the morphological definition of informality is still evident in Google Street View images. A possible explanation is an improvement of the social status with remaining morphological conditions and therefore, the classifier is not able to identify the correct class. Another factor, which has to be considered, is the misdetection of informal areas that have a morphologic formal appearance (i.e. structured housing rows or ordered street network). The official informal areas that were not detected by our RF model (Fig. 4 in red) are often loacted in the core of the city and are, according to Google Earth and Google Street View images, morphologically rather structured. To summarize, the identification of informal areas with EO data has its limitations and local knowledge is needed to better understand the reasons for misclassifications. Nevertheless, our model is able to detect a large amount of officially informal areas and furthermore, gives a more realistic and recent picture of the vulnerable areas at the city's edges. It can be concluded that the LCZ concept is a valuable instrument to identify not only urban structural types in general, but also informal settlements in particular.

City Afoot – What the State-of-the-Art Walkable City Looks Like

Susanne Tobisch, Angelika Psenner

(DI Susanne Tobisch, Dept. of Urban Design, TU Wien, Karlsplatz 13, 1040 Wien, susanne.tobisch@student.tuwien.ac.at)
(Assoc.Prof DI Dr.habil. Angelika Psenner, Dept. of Urban Design, TU Wien, Karlsplatz 13, 1040 Wien, angelika.psenner@tuwien.ac.at)

1 ABSTRACT

Walkability has been the subject of research for quite some time now. There are solid findings from a wide range of disciplines, and yet in reality the realization of pedestrian-friendly urban areas is rare. Why is that? Urban planning is a highly political undertaking; only a few politicians dare to incur the displeasure of the car lobby, the conservative economy and the - in their opinion - still car-driving and car-owning majority of voters. Rarely do decision-makers, like Anne Hidalgo or Leonore Gewessler at present, act seemingly free of fear of the next election. Regardless of this fact, the question arises: What would the state-of-the-art walkable city look like?

In addressing this question, this article not only provides a comprehensive research on walkability across the disciplines, but above all attempts to examine the findings to see whether they are suitable for implementation at all. For this reason, the second part of the text deals with the attempt to translate theoretical knowledge into the real-physical world within the chosen perimeter of the Vienna Westbahnhof site. The research by design method was chosen in order to transfer the partial knowledge about walking as a basic function of traffic science or as a leisure-immanent behavior, or about the parameters of quality of stay in public space into an inclusive planning basis. The aim was to detach planning from conventions and instead force a development of the built environment based exclusively on current walkability research.

2 INTRODUCTION

“Stop counting and comparing! We have all the necessary facts at the table and we already know what needs to be done. Let's finally do it now.” With these words, Ute Schneider, the new professor of urban planning, began her first studio supervision at TU Wien in spring 2021. In this sense, this paper follows this call and tries to translate a well-founded factual situation into design: how must walkability be designed?

2.1 Relevance of Walkability as a Topic in Urban Design

Cities around the world advertise the walkability of their town centers as a special feature in the quality of urban life. However, it is important to notice that the roots of pedestrian friendly structures are to be found in pre-automobile times, when pedestrians represented the primary user group of public space. With the rise of individual motorized transport urban development started failing to meet essential life quality standards. But since the matter of the finite nature of our resources has become a critical concern in recent years, the walkable city has once again developed into a major focus in urban planning–primarily due to its resource efficient and sustainable land-use and its low-emission transportation. In order to meet the needs of pedestrians, a number of concepts have been implemented, based primarily on the restoration of walkable historic structures.

But what would a new state-of-the-art walkable city look like today?

Walkability is a heavily discussed topic and covered in various research fields. A plethora of studies across the fields have found a relevant link between mobility behavior and the built environment. Mode choices and therefore also walking seem to be closely associated with it. While there are some interdisciplinary approaches, the bulk of the studies are within the borders of one field of research.

As urban structure researchers/architects/urban planners we seek to shine light on what a "most walkable city" would look like nowadays, by aligning interdisciplinary results from scientific walkability studies with the real built environment.

2.2 Research Questions and Methodology

2.2.1 Questions

Considering the abundance of established and new research material and the resulting theoretical knowledge on the topic; but the – comparatively – rare attempts of practical integration of the state-of-the-art walkable city, the paper is addressing two main questions.

First of all, the fundamental question arises as to whether currently valid research results in relation to walkability can be applied at all in a practical design process and thus implemented in a real reference field. Secondly, the question of the implementation problems that arise in this context are to be clarified.

In order to be able to address these questions, i.e. to assess which implications for the design of real urban structures can be derived from scientifically recognized valid findings, this paper provides a comprehensive, cross-disciplinary overview of findings from walkability research.

2.2.2 Methodology

Scientific Literature Study

An extensive literature study on walkability was conducted in various research fields. Walkability research is pursued in fields like urban planning, transportation research, spatial planning, public health, economics, psychology, sociology, geography, ecology, architecture and more. The amount of available material varies widely, with urban planning, transportation science and public health easily being the most productive disciplines. These three disciplines use different approaches: while traffic planning focuses on the length and availability of routes, public health emphases on the amount of time spent walking and the constitution of environment that encourages physical movement, not unlike urban planning which is also dealing with the constitution of public space and its influence on the walking and staying behavior of users. The scale of the analysis is similar in the first two, being on an urban or district level, while urban planning seems to go much more into detail down to street or building level.

The findings are then categorized into the so-called D-variables, which reflect the state-of-the-art in walkability research–and originate in the field of transport research– there they are described as the primary influences on walking: Diversity, Design, Destination Accessibility, Distance to transit. (Cervero and Kockelman 1997, 199; Ewing and Cervero 2001, 114) The study includes two additional variables: Demand management and Demographics. Both are treated distinctively in research literature because, although they are not part of the physical, built environment, they still have an undeniably significant influence on walkability. (Ewing and Cervero 2010, 267) Substantial correlations and cross-causal relationships between the individual influences are analyzed in order to better assess the relationships between the D-variables. Thus, walking is being studied as a basic function in transport science, and equally as a leisure-immanent behavior, and in connection with this, of course, the quality of stay of public space is being analyzed.

- Research by Design

Research by design is used to investigate spatial solutions for a research area in an iterative design process to produce new knowledge or practices considering the area or the objective in general. (Roggema 2017) The results from the theoretical treatment of the topic are thus translated into parameters that allow the development of a built environment that is detached from conventions and instead based exclusively on current walkability research. The parameters developed in this way are then applied to a research area in

Vienna. The multitude of different design benchmarks that influence walkability, from regional coherence and urban structure to the arrangement of seating and surface design, are all taken into account from the beginning of the planning process. The result of that process is then reflected upon concerning the utility of the previously developed techniques in achieving a pedestrian friendly urban structure as well as the overall walkability of the design. Furthermore, the processes and tools that are available in urban planning at the moment are examined concerning their ability to ensure the development of walkable structures.

2.3 Objective

The objective of this study is to investigate what the state-of-the-art walkable city looks like by conducting an extensive literature research and developing a design process based on the priorly obtained knowledge. The multidisciplinary, research-based approach to walkable city design is expected to reveal weaknesses and underrepresented issues in both theory and practice. The aim is to challenge and rethink common practices and existing frameworks in urban planning to build the foundation towards high walkability in the city of the future.

3 WALKABILITY RESEARCH

Research on walkability was initially conducted in transportation research and was therefore mainly considering influences on walking for transportation, while the leisure aspect of walking was originally not included in the definition. (Saelens and Handy 2008) Only when other fields of research engaged in the topic walking for leisure and – since they are inextricably linked – the quality of stay of public spaces were added. The term walkability is no longer only limited to pedestrians, but is often used to describe an environment that is suitable for other non-motorized transport like cycling and various leisure activities as well. (Kerr 2014, 131)

4 D-VARIABLES

As described earlier, the D-variables are outlined in the following and checked for their applicability.

4.1 Density

The most widely used parameters population density, employment density and building density are good indicators for the amount of urban activity in the city. They are easily assessed and therefore most widely used, but they cannot offer definite statements especially not in single use environments.[1] Variations of the factor network density – either considered for the general network (streets) or for the pedestrian network (sidewalks, crossings and passageways) – stated in network meters per square meter of area - are also often used.[2] The term attractor density was introduced in an effort to clearly describe the connection between the density of certain uses in the ground floor of buildings and the walkability of the adjacent street environment.[3] While parameters like building density and network density can directly be applied to a planning area, this is not possible for those relating to the amount of functions or people that populate the city. These need to be implemented in combination with other D-variables.

4.2 Diversity

From walkability's perspective, the key-uses in the city are living, working, supply, leisure and education. The connection between them is ensured by the sixth use, which is traffic. Spatial segregation of the uses (e.g. because of functional zoning that intends for large, single-use areas) increases the need for traffic and the distances covered, which results in a high degree of macro-mobility. Diversity of uses however ensures short distances between different functions, which makes walking, cycling and public transport feasible for

[1] That is why they could be considered as poxy variables for walkability. (Forsyth et al. 2007, 682)

[2] This does not seem to be taken into consideration in most newly planned areas, block dimensions are usually large to be able to accommodate big individual developments, the resulting street networks can therefore not be considered walkable.

[3] Functions in the ground floor of buildings are highly influential for the amount and type of activity in the public space in front of them (see section 4.3.2). While living and certain workplaces are only intended for a limited user group, other functions are able to attract additional people, whether that might be as pupils, customers or visitors. Those functions are responsible for a large part of activity in the public realm and therefore a direct indicator of the walkability of that environment. (Tobisch 2021, 37)

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

most everyday travel; thus, it generates a public space that promotes urbanity, i.e. a lively city life – which in turn, experience has shown, further increases walkability.[4] In practice, both the urban structure and the design of the buildings themselves need to be suitable for various different functions to enable a sustainable development of mixed-use environments.

Fig 2: Single-Use business district “Viertel Zwei”; Mixed-Use neighbourhood along the Märzstraße in Vienna © Tobisch

Uses outside of buildings, whether they might be in private or public spaces are usually not included in walkability research. Considering that these are most directly perceived when walking, their importance is evident and more attention needs to be placed both on the research and planning of these functions.

4.3 Design

Considering the multi-faceted effects of design aspects on walkability, the following sub-categories are introduced:

4.3.1 Functional Design

Functional design includes all design aspects that have the potential to shorten routes measurably. Because of the limited reach of pedestrians[5], permeability is one of the major restrictions of walkability, it is described by the factors intersection density and street connectivity. Pedestrian reach must be determined along the street network and not by linear distance, therefore the geometrical reach varies widely depending on network characteristics.

Fig 3: Permeability of different urban structures in Vienna, illustrated by the comparison of a 800 meters radius and the actual network covered with a travel distance of 800 meters in each structure respectively © Tobisch

An important statement is that intersections and street networks can only be equated with the walkable network in a pedestrian-only or shared space environment. In conventional street layouts where the different traffic strands are spatially separated, the pedestrian network does not consist of streets, but rather of sidewalks, intersections and passageways. Pedestrian sensitivity to detours at intersections and vertical routes such as under- and overpasses is high and further limits their reach, hence pedestrian connectivity must be carefully considered. The arrangement of buildings within the block and with that its permeability is highly

[4] While the number of individual activities seems to be the deciding factor for a space to be considered “active” the spread of those activities around the clock (Jacobs 1961, 154; Speck 2018, 14) and the length of the activities themselves (Gehl 2012, 72) are the key influences on the perception of the space.

[5] Various studies show that the willingness to walk decreases rapidly after only a few hundred meters. (Gehl 2012, 139; Walther 1973, 58-64) Precise statements about the reach of pedestrians are often made, but since they are dependent on a variety of factors (like walking environment, cultural and individual conditioning and availability of other modes of transport) and vary widely, they cannot be considered generally valid.

relevant for the length of the path that has to be covered to reach a destination, but also for the legibility of the public space and the perception of the functions on the ground floor.

4.3.2 Qualitative Design

Beside the distance factor, the environmental aspect is the main reason for encouraging walking: the path has to be attractive![6] What can be considered an attractive environment is determined by two factors, firstly the amount of space provided to pedestrians, which is in conventional street layouts indicated by the width of sidewalks.[7] The second factor results primarily from the circumstance of the comparably low speed of pedestrians and the resulting thorough sensory perception of the surroundings when walking.[8] Therefore, the public space needs to meet certain qualities and a and it needs to be interesting.

Fig 4: The two sides of the Wassergasse in Vienna display different structuring and information density; a configuration of a ground floor that enables interaction with the public space, and one that makes interaction impossible © Tobisch

Conventional urban maps portray only the public space but do not give any information beyond the building perimeter. But apart from the design of the public space itself, the ground floor of the adjacent buildings is the major factor of the perception of the city form a pedestrian's point of view.[9] This includes uses as well as the structuring and permeability of the façade that enable interaction between those vital spaces.

4.3.3 Quality of Stay

Walking is not a strictly linear activity and is often accompanied by stopping or longer periods of time staying at one place, consequently streets cannot be considered as places for traffic only, but must also be viewed as a place to stay.[10] Places to stand and sit, and factors like the soundscape, thermal comfort and protection from weather effects need to be taken into consideration. If a high quality of stay is provided people tend to engage into various other activities, which – through witnessing it – encourages more people to engage in activities themselves.[11]

4.4 Distance to Transit

Since walking as a mode of transport is especially practical for short distances, a network of public transport that is both dense[12] and offering frequent service is needed to cover longer distances at any given time. The density of the stations and therefore the coverage of the public transport system can only be determined by taking into account the characteristics of the street network, not by linear distance (see 4.3.1). A high availability of public transport also decreases the dependency on individual motorized traffic; This means

[6] An attractive walking environment can increase the distances pedestrians are willing to walk for travel reasons by up to 70% (Knoflacher 1996, 133) and has an even higher significance concerning walking for leisure. (Gehl 2012, 5)

[7] The width of sidewalks and them being free from obstacles reducing their width is relevant for traffic purposes – i.e. people walking next to each other or passing each other without having to step off the sidewalk – and also for quality of stay. (see section 4.3.3)

[8] Relevant are the visual, auditory and haptic perception of the environment as well as thermal comfort.

[9] The treatment of the public space, the ground floor of the adjacent buildings and private open space as one continuous entity is brought to attention under the concepts of the Stadtparterre (Urban Parterre) (Psenner 2014a, 5) and the City at Eye Level (Karssenberg and Laven 2016, 15)

[10] In Austria obstruction of traffic is prohibited and stopping without cause is not permitted on the sidewalks (§78 StVO) this legal situation shows that the streets are often intended as transit spaces. (Psenner 2017, 76/81)

[11] Research around the standards for quality of stay and the consequential social life has been conducted in various countries and the findings seem to be universally valid. (Whyte 1980, 94; Gehl 2012, 17; Kato et al. 1978, 2-6,38,46-65; Jacobs 1961, 35-37; Jonge 1967, 10–11)

[12] For low rank public transit like busses and streetcars, a distance of 400 meters from the point of departure to the nearest station was found to be tolerable, for high rank public transport like metro and city trains up to 800 meters of walking distance are deemed acceptable. (Walker 2012, 68)

less moving and stationary traffic, which ultimately improves the quality of the street space and thus the commitment to walking. In addition to public transport, shared mobility and mobility as a service concepts are also suitable to cover larger distances and encourage multimodal mobility.[13]

Fig 5: Quality of stay ensured by places to stand, sit and engage in various activities in different public places © Tobisch

According to the equidistance principle[14] the nearest station of the public transit system or nearest shared mobility vehicle and the parking spot of the private vehicle need to be at least equidistant to the users point of origin to ensure equal opportunity between the different modes of transport.

4.5 Destination Accessibility

There are two different types of Accessibility, firstly local accessibility, which mainly includes destinations that can be reached within a certain walking time or distance, this factor provides information on the walkability of a neighborhood or district. Secondly, regional accessibility, which encompasses all destinations out of reach for pedestrians, and therefore characterizes the connection to other centers or even cities.[15] Polycentric city structures are generally the most successful in providing both local and regional accessibility to all its inhabitants. Effective Accessibility is not often mentioned in walkability studies, but was found to be an important factor during the research. Several design parameters like sidewalk coverage, location of the entrance and barrier free access contribute to that.

4.6 Demand Management

While availability and costs of traffic infrastructure are not directly part of the physical, built environment, they still have a highly significant influence on walkability and are therefore included in this study. There are two control mechanism to decrease individual motorized transport (IMT) and increase pedestrian traffic. The first one is the principle of induced traffic – the increase of availability of traffic infrastructure directly followed by an increase in demand and vice versa.[16] This is true for moving as well as for stationary traffic. The second one is true-cost pricing for IMT.[17] Recent political efforts for the mobility turnaround are now starting to take the external costs of IMT into account with measures like carbon pricing (i.e. in the EU's Green Deal).

A general reduction of IMT liberates significant financial resources that can be redirected into walking developments and increases both the amount and the quality of public space that is available for other road users and for various activities.

---

[13] While station based shared mobility concepts can be treated similar to public transport considering the coverage of the service—the city of Vienna aims for a bike sharing station within 300 metres and a car sharing station within 500 metres for 40% and 50% of its inhabitants respectively until 2025 (MA 18 2015, 14)—concise statements about the coverage of free-floating models are not possible without site-specific analysis.

[14] (Knoflacher 1996, 214)

[15] Studies have shown that the two types of accessibility counteract each other to a certain degree, the effect of high levels in one category is most significant when the other one is low. (Handy 1993, 58)

[16] (Kent 2020; Knoflacher 1996, 35–37; Thomas 2013, 14; Speck 2018, 108)

[17] This includes the elimination of subsidies both direct (commuter allowance, tax benefits) and indirect (free or low-cost parking, required construction of parking space on private properties) as well as the consideration of all external costs (construction and upkeep of infrastructure, climate damaging emissions, noise pollution and additional costs in the healthcare system). (Frey 2007, 41; Shoup 2005, 2; Lewis and Adhikari 2017)

Fig 6: Public space in a typical secondary street that is primarily provided to stationary and moving motorized traffic; public space in a redeveloped street of the same width that provides space for various travel and leisure activities © Tobisch

A possible third mechanism is the supply of shared mobility as an addition to the already mentioned public transport. It represents a form of individual transport that needs less parking space because it displays higher levels of circulation and also decreases the need to own a private vehicle for occasional use.

4.7 Demographics

Various demographic aspects – like age, gender, educational level, level of income, lifestyle, ethnicity and cultural background - have an influence on walking behavior. Therefore, demographics are considered a confounding variable which means that their collection is important for the subsequent comparability of different places. From a design standpoint, sociodemographic influences are to be considered in an effort to develop structures and public spaces that cater to the diverse needs of various user groups.

5 RESEARCH BY DESIGN

Where:

The chosen research site–Wien Westbahnhof–used to be one of the major stations in Vienna, it is located on the western border of the city center. Its connection frequency was drastically reduced when the main railway station was opened in 2014, so that most of the structure has already been shut down. The Westbahnhofareal–which includes the station itself as well as the upstream track system and several maintenances buildings–covers an area of 0,3 km². It is situated directly in the compactly built and densely populated city center and has fairly good public transport connections. This provides all the necessary conditions for a high level of walkability, which could not be developed from scratch in an area of this size.

A generous perimeter was set for the area to be studied around the Westbahnhofareal in order to determine the status quo in terms of qualities and deficits and to locate possible effects on the site itself.

Setting:

The development of a framework for a walkable environment on the Westbahnhofareal was based on the findings of the literature analysis. Since the D-variables correlate heavily, parameters for each variable were put in place, analyzed and tested against interdependencies with the other variables and adjusted accordingly afterwards. The resulting iterative process of design, analysis and redesign considered all design benchmarks that influence walkability from the beginning of the planning process.

Stadtparterre–Urban Parterre:

The urban parterre–i.e. the zone that describes the parterre of the city and includes the ground floor, street space and inner courtyards (Psenner 2014a)–is given special attention in the chosen approach. Not least because recent studies have proven its undisputed relevance for the urban system. (Psenner 2021) It plays a special role with regard to the walkability aspect. In the extended study area, the given zoning was compared with the actual use of the ground floor zone and no significant correlation was found. Which suggests that the current system of zoning does not have a significant impact on actual use and therefore may not be the right tool to ensure functional diversity. In addition, the problem of under-utilization on the ground floor and vacancy is prevalent.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

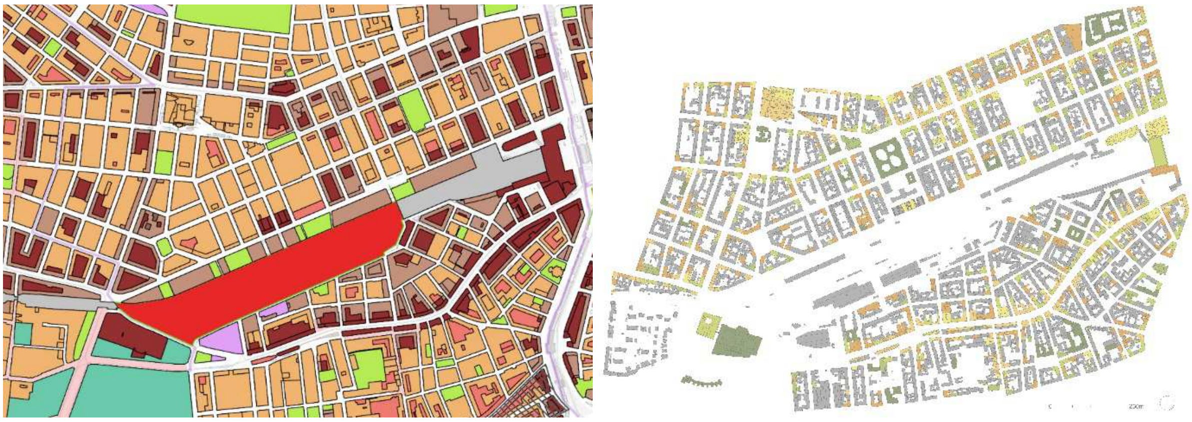

Fig 7: left: Zoning Plan of the Westbahnhofareal; right: actual ground floor uses (colour codes indicating different attractor uses like public, retail, business etc./non-attractor uses marked in grey) © Tobisch

The distribution of public space in the perimeter is characteristic for Vienna, most of the surface area is designated to IMT, both moving and stationary. Typical Streets are transit streets and offer low-cost parking continuously on both sides of the street.[18] With few exceptions, the streets dedicate more than half of the available space to cars, some even up to 80%[19], the remaining percentage is split between pedestrians, cyclists, public transportation and a few trees and leaves little to no room for activities other than traffic. Against this background, the urban parterre in its current state cannot be considered suitable for a walkable city.

5.1 Design

Since the chosen area poses several challenges – i.e. a remaining train connection, a steep topography and, as a local air channel, far reaching importance for the urban climate – and exhibits deficiencies – i.e. insufficient connection of the southern and northern part of the district – a design that increases both walkability on the site itself and provides improvements for surrounding area was pursued.

Thus, the existing street network and block size were taken into consideration when developing the corresponding counterparts on the site. The continuation of streets through the area was ensured wherever possible and additional paths were introduced where necessary, to provide optimal pedestrian connectivity. The building blocks were aimed to be 60-90 meters in side length to provide frequent route choice while still keeping the blocks big enough and suitable for building arrangement that can accommodate various functions as well as reasonable courtyards.

A large park located in the middle of the Westbahnhofareal keeps the local air channel intact; its vegetation provides an additional cooling effect on the urban climate; and moreover, it compensates the general lack of green space and space for recreational walking, sports and relaxation in the area.

Fig 8: left: Site plan, the block size provides frequent route choice and the park provides cooling and space for recreation; right: The pedestrian network provides optimal connectivity considering the topography and remaining train connection © Tobisch

The coverage by public transport is considered suboptimal for both, high and low rank traffic. Consequently, the designed street network is optimized for transit access and two additional stops are added to an existing

[18] Low cost on-street parking is in high demand, while more expensive parking facilities on private property and in garages are underutilized.

[19] Only exceptions found in the area are streets with public transportation and the few existing pedestrian zones.

bus line to ensure full coverage on the site and its surrounding area. In addition, a mobility concept for IMT and shared is developed. Collective garages located in close proximity to public transport stations represent the only parking possibilities for private cars and thus ensure equidistance.[20] Three shared mobility points are introduced to provide adequate alternatives to car ownership.

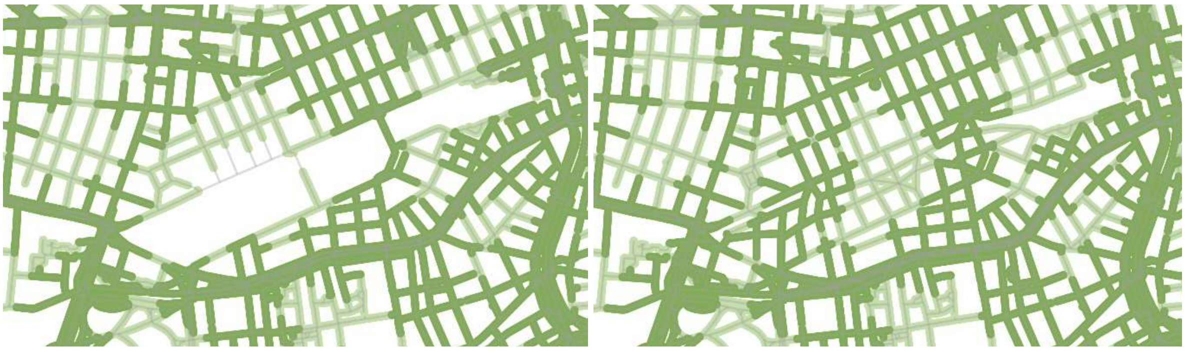

Fig 9: Isochrone map for low rank public transport for 200 and 400m distance, left: Status quo, right: Design © Tobisch, Hetzenecker

The top priority for the street design was a (re)distribution of the public space in favor of pedestrians and other non-motorized road users. They are not meant to be used for traffic only but also for lingering, therefore, all streets (with one exception) are residential streets. Seating, trees, water elements, bicycle parking and additional free space for various other activities invite residents and passersby to make the street a space to be lived in. Generally, one-way car access is limited to supply and delivery, there is only a single two-way transit street in the area which is sufficient to facilitate both access to the collective garages and the operation of public transport.

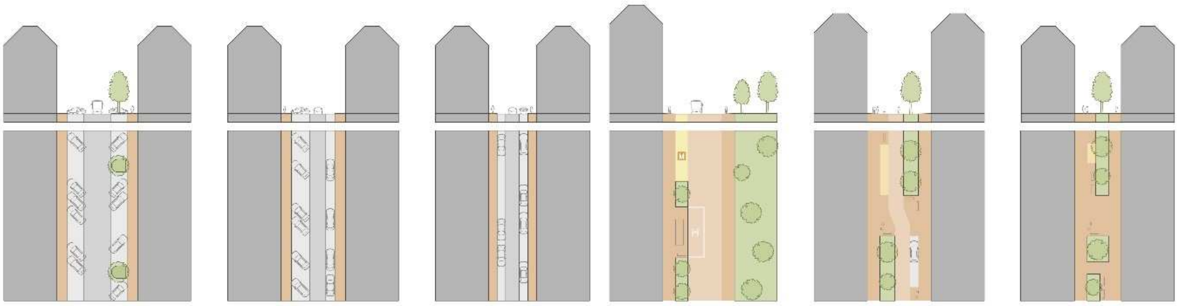

Fig 10: left: Status quo – more than 50% of the space in the streets is designated to stationary and moving IMT, right: Design – all new streets are designed as shared spaces that offer seating, trees, bicycle parking, generally limited one-way car access is possible, streets with public transport are two-way transit streets © Tobisch

Considering the size of the area and walkability as the only design objective for this study the results of planning further qualities to detail without additional data[21] would tend to get more arbitrary than scientific. Therefore, implementation of further planning steps was not carried out to detail but rather formulated in a list of qualities that includes: the positioning of buildings at the edge of public space, pedestrian pathways, semipublic courtyards, small plot size, visual and haptic permeability of ground floor façades, small size of functional units, treatment of ground floor as semipublic space (Psenner 2018), structuring of façades, arrangement of uses and seating in public space.

5.2 Comparison to Historic Structures

Since historic inner-city centers are what walkable environments mostly look like at the moment, the comparison of results of the design process conducted here and those known walkable structures were of interest. The designed structure offers wider streets and intends for generous semipublic courtyard areas with a direct connection to the public space, but the indisputably most notable difference is green spaces and vegetation. It is known that the high degree of sealing in traditional city centers causes a micro climate that is not compatible with the thermal comfort of pedestrians needed for high walkability – even more so in

[20] This does not comply with legal requirements in Vienna, which call for the construction of parking spaces on the property, the amount of parking spots required is derived by the use of the building and the square meters of floor space.
[21] Additional data might be objectives on an urban level (i.e. regional centers), target values (i.e. for uses like social housing, or population and jobs created) or specific uses on a block or plot level (i.e. schools, event locations) etc.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Vienna, where the 19th century city structure was mostly laid out without any trees at all. (Psenner 2021) Therefore, the developed structure offers trees in every street and a generous large park both for a cooling effect on the urban climate and as a place for recreational walking, sports and relaxation for the residents.

5.3 Learnings form the Design Process

The hypothesis that walkability can only effectively be established when it is considered at all planning steps was confirmed during the planning process. Which also means that existing structures cannot reasonably be adapted to reach the all mentioned qualities, though significant improvements are possible. Walkability as a concept is highly adaptive, deficiencies in some aspects can be compensated for by providing other qualities (i.e. steep topography limits the reach of pedestrians but can provide interesting views). It is quite clear though, that compensation of deficits is only possible to a certain point and potentially not for all aspects that contribute to walkability.

5.4 Weaknesses and Problems

Although the D-variables are highly influential on the walkability of urban environments, they are not properly differentiated from each other and correlate heavily. Therefore, it is not possible to assess the relevance of each one of them separately and quantify their precise influence on the walkability of a built environment.[22] In this study several aspects that are not originally included in certain variables have been added to draw a more complete picture of all of the influences on walkability.[23] Green spaces and trees are scattered through several of the D-variables and might therefore be easily overlooked. Given the great importance of vegetation for walkability (in atmosphere of surroundings, leisure walking, sports and relaxation, micro and urban climate) this can be considered a genuine flaw.

While the D-variables are highly usable when analyzing existing structures and categorizing research, they did not provide a linear framework for planning, the design process was therefore conducted in an iterative process of design, analysis and redesign along the various benchmarks but with the D-variables also in mind.

Several of the mentioned needs of pedestrians do not correspond to the legal situation in Vienna. This mainly involves the use of the street as space to linger, ground floor use and zoning in general, and the construction of parking space. (Psenner 2014b) In some instances, the appropriate tools to ensure a pedestrian friendly development are not available, i.e. when it comes to the permeability of ground floor facades. The implementation of walkability-concepts can therefore only be successful if appropriate policy changes are made.

6 CONCLUSION

The conducted scientific literature research and research by design process revealed that the theoretical knowledge on walkability can indeed be applied in a practical design process. The D-variables proved useful in categorizing the abundance of established and new research material and the resulting theoretical knowledge. They also provided a guidance for the subsequent translation of the research results into parameters for the design of walkable built environment. However, they do not represent the precise perimeter or the design of building blocks with which a walkable city can be assembled, but rather need to be understood as the foundation on which a creative design process can subsequently unfold.

The findings clearly unveil the qualities of a walkable city. Since the needs of pedestrians include structural, functional and qualitative design parameters and relate to all design benchmarks, walkability can only effectively be established when it is considered at all planning steps. Generally, structures must be designed to be functional and comfortable and offer a high quality of stay to encourage walking, but because walkability as a concept is highly adaptive, given deficiencies in some aspects can be compensated for by providing other qualities. The urban parterre plays a special role in regards to the walkable city since the street space and the ground floor of the adjacent buildings are most directly perceived while walking. Its functioning is highly dependent on the legal situation; therefore, the planning of a walkable city can only be successful if the appropriate policy changes are made.

[22] The shortcomings of the D-variables as found in this study have been addressed before. (Handy 2018)

[23] This deficit stems from the origin of the D-variables in transportation research, where parameters like quality of stay are not paramount.

1 ABSTRACT

The Austrian Panel on Climate Change (APCC, 2014), as well as the next report version (2021) emphasise that spatial planning policies have to be empowered to combat climate change. While the 2014 version contained a rather modest presentation of spatial planning and mobility approaches, the future version will have a full chapter on “spatial planning and climate change”. Usually, APCC reports tend to trust sources that are highly validated and highly agreed upon by many experts. “Climate proofing” should be a process to measure the mitigation and adaptation impact of spatial strategies and programmes, but so far there is only poor evidence that this exists: we believe that spatial planning is powerful, but it is hard to prove this in qualitative and/or quantitative terms and numbers.

Keywords: criteria, policy, strategy, climate proofing, spatial planning

2 INTRODUCTION

The Institute of Spatial Planning at TU Wien has already organised two courses under the branding “Planners for Future” to fill this knowledge gap, and to improve learning about climate proofing for spatial planning policies, one of the successes of these lectures was the founding of the "build for future" group, an association of architecture and spatial planning students (Build for Future 2021), organised as subunit of “Friday for Future”. This paper reports on three selected spatial strategies, comparing their status on environmental impact today with a clearly improved future “version” to show our results.

One case study dealt with the expansion of ski areas in Tyrol. The Spatial Planning Act, the Nature Conservation Act and the cableway programme of the federal state were examined for indicators on climate-friendly developments. The results showed that there were no clear parameters in all three instruments. As a consequence, we developed an evaluation tool for such extensions. This is a two-phase-system, which provides for a point system in combination with “K.O. criteria” (i.e., snow reliability, glacier protection and protected areas).

Whereas Austria is still the European champion in terms of land use, the German concept of the “Eco Account”, which prescribes compensation measures for construction projects, was examined for effectiveness. Again, a lack of proportionality was found and an adapted climate proof version, based on qualitative and quantitative indicators, was developed for Austria.

Another topic introduced in this paper is the problematic amount of secondary residencies in several touristic regions e.g., Wörthersee, which lead to increasing vacancy, land use and rental fees. In order to establish a climate friendly and sustainable development in that region, two international vacancy taxations (France and City of Vancouver) were compared and adapted to the spatial requirements of the Wörthersee region. If applied, the vacancy rate in this region would be reduced by 25 percent and up to 50 percent within five years.

So far, a few findings around the climate proofing of spatial strategies and policies are possible: there are a lot of reports and analyses criticising the lack of “evaluation culture” around climate proofing of spatial strategies and policies, but still very few attempts to really try exactly that. Also, many experts emphasise the necessity of “adaptive resilience” (Jesse et al. 2019) instead of former mitigation approaches, but they don’t show workarounds on how to improve this „climate proofing toolkit“ for spatial strategies and policies. At the TU Wien, we will go on to work on that toolkit, improving the given methods and developing new ones that will definitely use more criteria than the CO2 balance.

3 STATE OF RESEARCH AND METHODOLOGY

The connection between spatial planning and the climate crisis has entered the scientific discourse. We, as spatial planners, presume to create resilient cities and regions through sustainable and foresighted spatial development (e.g. city/region of short distances, mixing, provision of public services). Yet in the past and probably the future, certain development trends (e.g. individual traffic, urban sprawl, soil sealing) did and will not correspond to this goal. Responsibility for this is generally assigned to policy makers. Yet even as spatial planners ourselves, we only have a very limited knowledge of the impact that spatial planning policies, instruments and programmes actually have on the climate crisis.

As part of the Climate Proofing course, students analysed selected strategies, instruments, and programmes for their ACTUAL impact and outlined TARGET proposals. The basis for this analysis was a jointly developed criteria grid, which shows in which areas there is a lack of information and data to support statements quantitatively and qualitatively. The course proceeded as follows using a concrete spatial context (regional or neighbourhood/settlement) as a basis:

- Jointly develop indicators (for impact strength) and criteria (for the transformative transition between ACTUAL and TARGET)
- Analysis of selected plan documents, programmes and instruments (to what extent these are aligned with adaptation strategies of the climate crisis and what the impact strength is in the ACTUAL and TARGET to be assessed)
- Recommendations for action and suggestions for improvement (increase of effectiveness, repeatability).

In the instruments of spatial planning, there is a shortfall in liability between the smallest unit (individual buildings) and an entire federal state. This is true regardless of whether they are directly spatially effective instruments (e.g. settlement expansions, developer inside competitions) or the "classic" indirectly spatially effective instruments (e.g. subsidies). Regions are one such spatial category for which often no one is explicitly "responsible". For subspaces, e.g., neighbourhoods, relevant data is often not available. Within the framework of the course, a conscious attempt was made to model such " understeered intermediate spaces" in their climate balance. The three selected case studies (ski area assessment, landscape account, mobilisation of unused dwellings) identify missing information and missed potential and give an insight into what they could achieve.

4 CASE STUDIES

4.1 Ski area expansions in Tyrol

A screening of the Regional Planning Act, the Nature Conservation Act and the cableway programme of the Federal Province of Tyrol for climate-relevant factors was carried out. Included were those that are also of particular relevance for the sensitive alpine ecosystem. Initial results showed the following:

First and foremost, purely economic factors, such as profitability or competitiveness, are used in the instruments for assessment. Although soil and nature conservation are addressed, concrete measures or demands for climate protection are not mentioned. In practice, the nature of the existing indicators allow even climate and environmentally damaging location decisions for ski resorts to be presented as "environmentally sound" (Hahn et al. 2020).

The student group developed a simple but effective two-phase ski area assessment tool to address this. The first phase of the assessment includes three crucial criteria (snow reliability[1], glacier protection[2] and protected areas[3]), which determine whether the project should be considered at all. Only if all three criteria are met (1. the area has snow guarantee; 2. glacier areas are not affected; 3. protected areas remain

[1] Snow thickness from 30 to 50 cm; presence of snow in 7 out of 10 winters; snow cover from the end of December to the end of March (Schickhofer 2017).

[2] Rapid glacier retreat is the most obvious feature of climate change in the Alps. If the project affects a pristine glacier, it will fall through the review.

[3] The area apportionment of protected areas should no longer be valid. If an area is protected in any form, it must be absolutely unassailable.

untouched) can phase two be applied. For this purpose, seven additional criteria were defined (Table 1), which have been assigned a rating from -1 to 3. The higher the score, the more sustainable is a realisation of a ski area project in terms of climate protection, but a total of 2/3 of the points must be achieved to pass the Climate Proofing.

Using this list of criteria, two expansion plans in Tyrol were evaluated by the group. The St. Anton Kappl extension as well as the Ötztal-Pitztal link do not fulfil the prescribed criteria of the first phase. Even if this was the case, it had not been possible to carry out a climate proofing under the specified factors for both projects due to lack of accessibility to the required data.

Criteria	Scale: -1 (very poor) to 3 (very good)
Elevation	Up to 2000m = 3 points; 2000-2250m = 2 points; 2250-2500m = 1 point; above 2500m = 0 points.
Ecological footprint	Ringler (2017) derived a value system for the ecological footprint of ski resorts. The range is from 5 (Oberschwende) to 120 (Sölden). 0-30 = 3 points; 30-50 = 2 points; Over 70 = 0 points
Positive displacement effects	In rare cases, ski area connections lead to positive relief effects (e.g. traffic load, utilisation pressure). If this is to be expected, it should be rewarded.
Land consumption of new slopes	The more area is used, the less points should be given for this. 0-10 ha= 3 points; 10-20 ha = 2 points; 20-30 ha = 1 point; 30 ha + = 0 points.
Compensatory measures	If compensatory measures are provided beyond the environmental impact assessment (UVP) in the case of an extension, this is to be positively rewarded with points.
Maximum CO2 value	Every expansion is accompanied by CO2 emissions during construction and later during operation of the plant. Maximum permitted limit values would have to be introduced here.
Maximum water consumption	In view of the fact that less water will be available in the Alpine region in the future, the water consumption of existing snowmaking systems must be determined in advance in the event of an expansion. If this exceeds the maximum value to be defined, an expansion would have to be prohibited.

Table 1: Criteria catalogue for climate proofing of ski area expansions in Tyrol by Hahn et al. 2020

4.2 Eco account for Austria

In order to minimise the ecological consequences of construction projects, the so-called prohibition of deterioration was established in the 1970s in Germanys Federal Nature Conservation Act. It is based on the following consideration. For a construction project (regardless of its size and the initiator(s)), an ecological compensation action (for example, unsealing, renaturation, woody planting or measures to protect biodiversity and species diversity) must be taken, because in principle, no deterioration for nature and landscape may result from this construction project (Wende et al. 2005; Froger et al. 2015).

The compiled criticisms of the student group (Doden et al. 2020b) are as follows:

There is a disproportionality between intervention and compensation. The compensation areas are too small to be seen as compensation

The compensation areas are not site-specific, i.e., for example, an affected community does not have to benefit from a compensation measure even though a construction project is being carried out there.

Instead of implementing a compensatory measure, it is also possible to make compensatory payments to an "eco-account". This can subsequently be used to carry out measures. However, these compensation payments are disproportionate to the actual costs of the compensation area, as they are much cheaper.

The most important thing for a possible implementation in Austria is therefore a plausible specification of the proportionality between intervention and compensation, in order to reduce the negative impact on the environment and to compensate it on a high level. The abstraction of interventions in nature should be avoided by a clear intervention-compensation key, with a focus on areas.

Transferring the concept to Austria, this instrument could look like this. In the case of an intervention of size x, another area of size x must be qualitatively upgraded and another (also of size x) must be de-paved. This results in an impact-compensation ratio of 1:2. However, there is the possibility to reduce the compensation measure through adaptation or mitigation, i.e. compensation within the impact area. Since the German model has no specifications as to where these compensation measures should take place, the idea was expressed here to include an additional factor with regard to the distance radius.[4] This should ensure that the immediate surroundings also benefit (Doden et al. 2020a).

The previous specifications for the "eco-account" in Germany still have few criteria for climate protection, which is why the student group created three qualitative and three quantitative indicators for the evaluation of the construction projects (Table 2), in order to be able to carry out climate proofing for the accruing projects here as well. Together with a sensible measure of site-specific and obligatory compensation measures, it is possible to estimate the impact on climate change.

QUANTITATIVE		QUALITATIVE	
Land consumption	Area ration between replacement area and intervention area	Interdisciplinarity & Diversity	Gender distribution during procedure implementation
Area equity	Building/green space ratio and accessibility	Environmental Justice	Arrangement of the areas to the settlement area/impact on the quality of life, popularity of the city.
Climate Change Adaptation	Expansion/maintenance of critical infrastructure (e.g. flood protection)	Climate Change Adaptation	Quality of nature conservation/ecological & temporal sustainability of measures/environmental education.

Table 2: Indicators of a Climate Proofing by means of a Landscape Account in Austria by Doden et al. 2020a

4.3 Housing activation contribution

At the intersection of protecting key soil functions and reducing greenhouse gas emissions is the examination of sustainable settlement development on the basis of a vacancy tax (David et al. 2020). The taxation of vacant housing serves policy makers as a market-activating instrument to limit speculation (voluntary vacancy) and the associated problems of housing availability (Segú 2020). Existing analyses are extended here by the aspects of "climate impact". For this purpose, international examples of vacancy taxations were analysed and possible applications in Austria were discussed. The models were not created with the aim of being exact forecasts, but rather to visualise the potential of a housing activation contribution or vacancy tax as climate mitigation policy (David et al. 2020).

The Empty Home Tax (EHT) was introduced in Vancouver in 2016. Homes that are declared, designated, or deemed vacant are subject to an annual tax of 1% of the assessed taxable value. In other words, a constant tax rate based on property value. Vacancy rates have already been noticeably reduced in four years and more housing units have been added to the market (City of Vancouver 2020). The "Taxe sur les Logements Vacants" (TLV) was passed in 1998 with the aim to bring more apartments onto the market. Apartments that have been vacant for at least two years were taxed at 10% of the rental price. If vacancies persist, the tax rate also increases. Relevant effects on vacancy rates have been demonstrated (Segú 2020).

	0 SCENARIO Development without intervention in the Wörthersee region	SCENARIO 1 Taxation based on Vancouver model Consistent tax rate based on property value	SCENARIO 2 Taxation based on the French model Increasing tax rate based on presumed rent charged
Change in vacancy rate	0%	-51,5%	-24%
Effect on CO2 emissions from new buildings	+120.400t	-142.900t	-66.700t
Change in sealed surfaces	+10,71ha	-18,56ha	-8,56ha

Table 3: Comparison of the scenarios up until the year 2026

Potentials of the application in the Wörthersee region are modelled by the students in three scenarios until the year 2026: A zero scenario, an implementation of a vacancy tax modelled after Vancouver's EHT, and a scenario developed after France's TLV. The zero scenario is intended to represent the development of vacancy without planning or political intervention, with a constant percentage of vacant residential buildings and an extrapolation of the average new buildings 2011-2018. For the applications of the respective vacancy levies, the empirical percentage changes on the units added to the housing market were adopted for the Wörthersee region. This was based on an idealised model in which the activation of vacancy leads to a

[4] Within the 5 km radius, the general provisions apply. However, if this distance is exceeded, the area already determined for compensation is calculated with a factor of 1.1. For each additional 25 km of distance, the factor is increased by 0.2.

termination of construction activities. The achievable positive effects for the housing market and the climate balance can be seen in Table 3. The CO2 savings effects were calculated using a primary energy approach: what amount of CO2 would be saved if additional new housing units did not have to be built in the first place while mobilising existing housing.

5 DISCUSSION

Before conclusions can be drawn about how future climate proofing work should be done, it is important to establish the conceptual framework within which any climate proofing can and should operate. While there has been (Birkmann und Fleischhauer 2009) a strong awareness for over 10 years that spatial development is appropriate for climate change mitigation, a serially proven and versatile "toolkit" for doing so is still lacking. This is a very unsatisfactory state of affairs, especially for future planning practice, because in the context of resilience, we have long had to assume transformative resilience, rather than adaptive resilience (Hat und Stöglehner 2019). Transformative resilience entails using the climate crisis as a lever to achieve a new target state, because the "old" state would merely lead to the time before the crisis. The students' analyses presented show how any spatial developments can be subjected to climate proofing using the "toolkit" of simple sets of criteria. These were able to coherently integrate both mitigation and adaptation measures.

An example of how the assessment toolkit of site planning has not yet arrived at climate proofing is, for example, that while the environmental impact assessment tool is capable of modelling the effects of a siting decision in great detail, it is not suitable for arguing this in a much larger system boundary of climate adaptation, or the principle question of the "necessity" of the project is not asked. In short, this tool is designed to do something it was not designed to do in the first place. In future designs of climate proofing, it will therefore be important to define and test both process- and subject- and object-related measurement criteria (Birkmann und Fleischhauer 2009). The reflection between the statement of quantitative and qualitative measurement criteria must lead into a "double loop learning", which means that phenomena are not only understood and measured, but new spaces of interaction are created through participation and education processes (theLivingCore 2019).

6 CONCLUSION

The course Climate Proofing of spatial planning instruments in Austria has fulfilled the claim of not only trying out climate proofing, but also opening up new spaces of interaction in the process, through an impressive and versatile set of criteria. In this set, the much-vaunted CO2 is merely a supporting actor (albeit an important one!). The four most important categories and findings were:

Area criteria (including saved sealing in m², ratio between intervention and replacement areas).

Processual and behavioural criteria (e.g. footprints of mobility and consumption behaviour between ACTUAL and TARGET, change in quality of life, but also fairness and diversity in the mapping of actors in the decision-making processes)

Primary energy criteria (CO2 savings through mobilisation of existing buildings instead of additional primary energy expenditures through new buildings)

Future criteria (respecting FUTURE environmental conditions including appropriate back-casting of current strategies, e.g. evaluation of future snow reliability and the amount of heat days).

A general challenge in climate proofing is the lack of data basis or access to data sets. Another weakness of already existing climate proofing is the lack of or inaccessible method documentation. This makes the comparison of findings and benchmarks impossible and precludes further development and discourse. However, the fact that there is “no data” (or just poor data) is not an excuse for neglecting climate proofing research nor investing creativity. Herein, creativity means to develop alternative research patterns. This means to collect data oneself, or (if not possible due to resource shortage) to use not obviously meaningful, but related data as proxies and to interpret them with regard on their value in climate proofing statements. The case studies presented in this article show exactly this way of working in an outstandingly successful and convincing way.

With further case studies or a creative extension of such criteria, the climate change impact of spatial planning instruments could at least be made more comprehensible in the future and, after these learning effects, it could be better ensured that these instruments could develop a considerably increased binding force and seriality, especially in the "under-controlled intermediate spaces" (Department für Raumplanung 2014). Future research on climate change and climate proofing should follow the “polluter pays principle”, in addition to the aspects of an increased seriality and liability of the policies (as mentioned before). The examples shown in this paper have their spatial focus in rural areas, this orientation might fit well for Austria (with about 35% of the people living in cities), but not at all for the future elsewhere: Globally, the proportion of people living in cities is currently 55%, in only a few years it may be 65% or more. This means that dense urban structures should be given more attention in climate proofing in the future. Here, the experiences from climate proofing experiences in rural areas could be adapted and promoted.

Finally, the question arises who will coordinate the international research with the goal of the "best possible" climate proofing methods. The authors of this paper believe, that this role should be filled by the IPCC (International Panel on Climate Change), and also by a much stronger policy prescriptive character of the climate change assessment reports.

1 ABSTRACT

The interest in automation and robotics in the construction field has grown significantly in the last decade. Smart cities and smart construction depend mainly on applying the concepts of industry 3.0 and 4.0 which adopt the smart construction concepts. They include automation, 3D printing and robotics. Virtual and augmented reality along with the internet of things (IoT) can be useful tools for applying automation and coordination between the operators, engineers and autonomous machines. Construction faces problems after the pandemic due to large on-site crew and machines being used by workers side by side; thus automation is an efficient solution for construction after the pandemic providing a safe environment for working.

This paper is an analytical research work focusing on using robotics and autonomous machines on-site in different construction tasks to mitigate the pandemic effect. It analyses the impact of on-site automation and the challenges facing it. The case study presents a methodology for using integrated on-site robotics and machines and analyses their impact on tasks planning and execution. It ends up with a concept for applying integrated robotised construction on-site depending on smart construction concepts; thus reducing problems that arise when using single tasks robots as site planning and interference of robotics. Also this allows reducing on-site workers and applying social distancing responding to WHO measures as well as solving congestion on site which is necessary for the pandemic constraints.

Keywords: Automation, Robotics, On-site factories, Pandemic, Prefabrication, Construction 4.0.

2 INTRODUCTION

The pandemic affected the construction sector and led to delays and pausing of projects (Alenezi, 2020). This is due to the complicated nature of construction sites where several tasks are executed in parallel. The construction industry lags behind the manufacturing industry in applying advanced technologies. While Japan has been developing and applying automated construction and robotics more than twenty years ago, the construction industry in Egypt still relies on large on-site crew and hazardous working methods (Bock, 2008; El Safty et al., 2012).

Automated construction involves using single task robots for performing specific finishing tasks, material handling and assisting human workers on-site. It developed from working indoor and in factory settings to working outdoor in facade finishing tasks and up to building components assembly (Melenbrink et al., 2020). It also involves general purpose robots as drones, exoskeletons, 3D printers and cable driven robots. Automation levels ranges from operator assistance and up to full automation depending on the nature of tasks performed and site conditions (Bock & Linner, 2016a) However Harari (2016) stated that automated construction differs from automated automobiles industry.

This research objective is to prove that shifting to automated construction and coping with industry 4.0 concepts will be essential to mitigate the pandemic's effect. And to discuss the automation effect on the site's safety and human workers on-site, showing whether automation replaces or cooperates with workers.

In order to achieve these objectives, a literature review of the potentials of automation for the construction sector and the challenges facing construction due to the pandemic was carried out. Then a case study is performed for construction after the pandemic from pre-construction phases to full execution based on the precautionary measures requirements and the autonomous solutions selected for an educational building. The research ends with a discussion of the effect of automation on the construction industry, the challenges facing automation application and a concept for applying construction after the pandemic according to construction 4.0 principles.

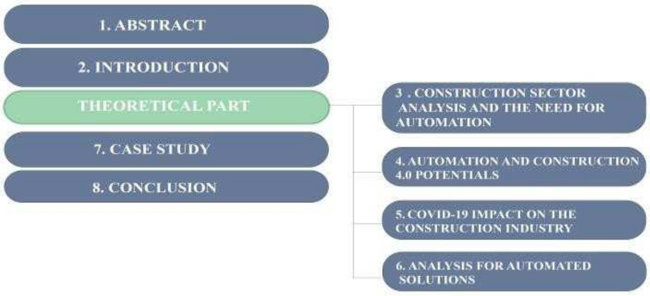

Fig. 1: Research parts (Researchers, 2021)

The research is divided into parts (fig. 1) including a literature review for the construction sector status, the need for automation and its potentials along with construction 4.0 concepts. Then a case study is performed for the automation of an educational building, ending with a concept for applying automation after the pandemic.

3 CONSTRUCTION SECTOR ANALYSIS AND THE NEED FOR AUTOMATION

The construction industry represents about 10-15% of the annual GDP (gross domestic product) of Egypt and enrols almost 15% of the Egyptian manpower (American Chamber of Commerce in Egypt (AmCham), 2020). However, workers are subjected to significant hazards that can result in fatal injuries or death in construction sites. Statistics show that the construction industry critical injuries are about 55,000 yearly (El Safty et al., 2012).

According to Manzo et al., (2018), it is possible to automate about 49% of all construction tasks. The automation potential is approximately 35% for labourers; it is 50 % for carpenters, 42%t for electricians, 50% for plumbers, and 88 % for operating engineers. Whereas in the next few decades, crane operators and bulldozer drivers could be displaced by AI-controlled machines.

4 AUTOMATION AND CONSTRUCTION 4.0 POTENTIALS

According to Lee et al., (2018), the fourth industrial revolution emphasises that the base for revolutionary changes in the construction industry is shifting towards digital and information technologies. This in turn enhances the creativity of organisations and leads to better quality assurance. Munirathinam (2020) stated that interconnectivity, automation, machine learning and real-time data are the key concepts of industry 4.0. This enables proper planning and information circulation throughout the project phases. BIM (building information modelling) plays an important role in design and coordination as well as 3D printing; it also enables programming of single-task robots motion and paths. Prefabrication, off-site 3D printing and modular construction market are expected to increase after the pandemic as it allows fabrication of building components in factory settings; thus reducing on-site congestion and decreasing on-site tasks to assembly work. For efficient structure assembly of components, the robot-oriented design concept (ROD) must be applied in the design phase as the assembly is performed by single-task robots or on-site factories. Unmanned aerial systems as drones can be aerial or terrestrial and it is used for inspection and surveying. Work assist as exoskeletons and robots help workers lift heavy loads and decrease injuries (Davila Delgado et al., 2019).

5 COVID-19 IMPACT ON THE CONSTRUCTION INDUSTRY

According to Breisinger et al., (2020) the construction sector employs a large share of Egyptian labour. The government managed to run the projects during the pandemic while monitoring the application of precautionary measures in the construction site; as decreasing the number of workers and social distancing. The construction activities witnessed a decrease of 5% during the pandemic. The pandemic affected the construction sector as a result of the travel ban and lockdown. The material supply is also affected by the lockdown. Social distancing and precautionary measures led to decreasing the number of workers on-site and shifting work and meetings from the conventional work methods to working virtually.

The travel ban affected the material supply and international specialists' presence. The lockdown reduced the working hours and productivity leading to contractual problems. Companies started reducing staff which led to unemployment (Al Amri & Marey-Pérez, 2020). The construction projects' delay was determined as a critical delay. This occurs when contractors do not finalise the project in the contract period (Alenezi, 2020).

According to the (MAP, 2020), the construction sector income witnessed a decrease due to several factors including the materials shortage. The steel production had significantly decreased whereas the cement production slightly increased. This is obvious in the GDP which declined to 8.1% in the second quarter of the fiscal year 2020.

Construction projects were paused due to the lack of demand by the customers, supply chain problems or difficult working conditions during the lockdown with safety measures and government restrictions. This has affected the economy negatively and workers became jobless (Wallace-Stephens & Morgante, 2020).

The labour cost is estimated to increase compared to machines that can still work in close proximity. This is due to the fact of labour shortage due to social distancing and partial lockdown, while machines do not require social distancing or hygienic measures (Wallace-Stephens & Morgante, 2020). Therefore the pandemic accelerated the shift to automation in several industries. The use of robotics in construction reduces communication between humans and could be a good choice instead of them. Robotics are more reliable and efficient and less costly. Also they can be controlled remotely so there is no need to be on- site (Chen et al., 2020).

(Wallace-Stephens & Morgante, 2020) described the construction industry as high Covid-19, high automation risk. It employs mostly men with high levels of young workers (under 30) who are expected to have low levels of education and are lower paid.

In the design phase, engineers and planners worked from home which saved much time and cost. However, working from home cannot displace the site visits and real meetings. Virtual site visits can be a choice for foreign specialists and external visitors; hence virtual reality will play an important role in construction sites (Jones et al., 2020).

Online meetings decrease cost and time and facilitate coordination between the project's teams and stakeholders. This enabled the stakeholders and client to monitor the project progress on site. Videos and digital aids are used to track work progress, safety measures and absent workers on site (Jones et al., 2020).

6 ANALYSIS FOR AUTOMATED SOLUTIONS

This section presents an analysis for automated solutions which can be applied on-site throughout the different phases of construction. Starting from the site preparation phases, substructure work, superstructure work and ending with finishing work. Material handling and storage can also be automated to store and deliver material in time to specific locations. Several systems have been developed by different companies, some examples have been used on-site while others are still in the conceptual phase. The examples presented in this section are the most convenient ones according to the project requirements and degree of automation. However, automated systems are not limited to the mentioned examples.

6.1 Site preparation phase

Excavation and site levelling work is considered a mature technology. A number of autonomous machines have been developed for construction in contrast to the mining industry (fig.2). Research in automation of those tasks is still in progress and only concepts are available as Volvo's autonomous solutions (fig.3). However, add-ons for upgrading conventional construction equipment are being used to achieve different levels of automation; including hardware add-ons (fig.4) or software for programming machines (Bock & Linner, 2016a).

Fig. 2 (left): Automatic Digging and Soil Removing robot (Tokyu, 2016) Fig. 3 (middle): Volvo compact excavator (Volvo, 2021)
Fig. 4 (right): Add-ons for conventional equipment (ASI, 2016)

6.2 Substructure work

The Pile driving process can be automated based on a 3D model for the soil and piling plan (fig.5). It cuts piles to the desired length after the driving process and allows real-time calculation of the soil parameters during the process (Hovila, 2012).

Fig. 5 (left): Pile driving machine (Hovila, 2012). Fig. 6 (middle): Reinforcement placing robot (Kajima, 2016). Fig. 7 (right): concrete distributor (Kajima, 2016).

For reinforcement positioning, Kajima's reinforcement positioning mobile robot is used (fig.6). While concrete casting is done using Kajima's rail-guided concrete distributor (fig.7). Concrete levelling and compaction are executed using Fujita's Concrete Floor Levelling Robot (fig.8) (Bock & Linner, 2016a).

3D printing using concrete is performed using the gantry system COBOD (fig.9) developed by Peri. Kajima developed positioning and joining of vertical reinforcement robot (fig.10) (Bock & Linner, 2016a).

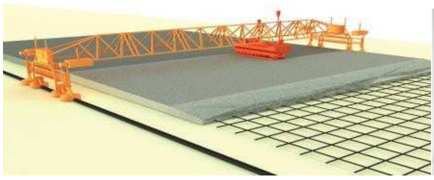

Fig. 8 (left): concrete levelling robot (Kajima, 2016). Fig. 9 (middle): CBOD 3D printer (Peri, 2021). Fig. 10 (right): Vertical reinforcement robot (Fujita, 2016).

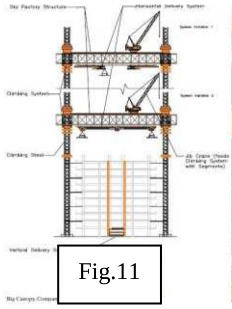
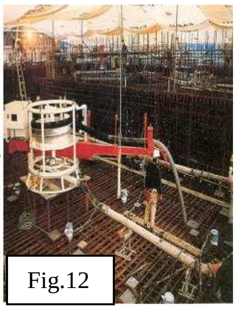
6.3 Superstructure work

For handling, assembly and repeated positioning tasks, the big canopy on-site factory is used (fig.11) (Bock & Linner, 2016b). Concrete casting work is done by the compact concrete distribution robot (fig.12) by Kajima which can be programmed or manually guided by a worker. Reinforcement is positioned using the Automated Crane developed by Takenaka (fig.13). The reinforced concrete cores are 3D printed using the COBOD printer (Fig.9).

Bricklaying is performed using fastbrick Hadrian system (fig.14) which is mounted to a truck on which bricks are stored. Another example is SAM100 (fig.15) bricklaying robot which has high productivity and is compact enough to be used on upper floors (Bock & Linner, 2016a).





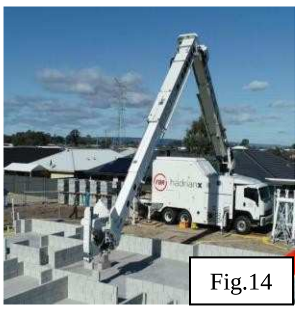


Fig. 11: Obayashi on-site factory (Bock, 2016). Fig. 12: Concrete casting robot (Kajima, 2016). Fig. 13: Reinforcement positioning crane (Takenaka, 2016). Fig. 14: Hadrian system (fastbrick, 2021). Fig. 15: SAM100 (construction robotics, 2021).

6.4 On-site material handling and storage systems

Obayashi developed an automated on-site delivery system consisting of automatic transfer equipment, automated forklift and automated storage rack (fig.16); hence enhancing autonomous operation. Other material handling systems include the Kajima rail-guided system (fig.17). It is more efficient by being programmed after standardising the routes and allows coordinating with the arrival of the materials on-site. Takenaka developed a mini-logistic unit for material transfer (fig.18) (Bock & Linner, 2016a).

Fig. 16 (left): Material handling system (Obayashi, 2016). Fig. 17 (middle): Rail-guided system (Kajima, 2016). Fig. 18 (right): Automated mini- logistics unit (Takenaka, 2016).

6.5 Finishing Tasks

Finishing tasks include exterior finishing for façade work, as well as interior finishing. Interior finishing includes tile work for floors and walls, wall painting, partitions' and ceiling panels installation.

6.5.1 Exterior façade components installation

Exterior finishing involves the installation of façade glass panels, painting work. Façade panels are installed using two robots depending on the panels' size. Kajima developed two systems for this purpose. A system installed on the roof (fig.19) to assist in lifting large panels while the final fixation is done by workers from inside the building. It operates from the roof by an operator. Another system is the compact lightweight system (fig.20) which assists in panels' installation while operating from inside the building; this in turn limits the panels' height installed and can be used for small windows and façade beams (Bock & Linner, 2016a).

Fig. 19 (left): Panels' installation system mounted to the roof (Kajima, 2016). Fig. 20 (middle): Panels' installation on-floor system (Kajima,2016). Fig. 21 (right): Façade painting system (Kajima, 2016).

6.5.2 Facade painting

Facade coatings, spraying and full painting stages are performed by Kajima's painting robot suspended from the roof (fig.21). The material supply system is located on the ground floor and supplies material via a hose. It has a sensor designed to detect wall irregularities and facade elements and openings to avoid them. It has a productivity of up to 290 m2/hour (Bock & Linner, 2016a).

6.5.3 Interior finishing tasks

For tile setting, FCL developed a robot that can be programmed, fully or partially automated. It consists of a mobile platform that can move on tiles and has a storage area on board, a control and power supply unit and a suction end-effector for holding tiles (fig.22). It requires a worker to assist in corners and critical areas by cutting and placing tiles and can work with other similar robots 24/7; thus increasing productivity (Bock & Linner, 2016a).

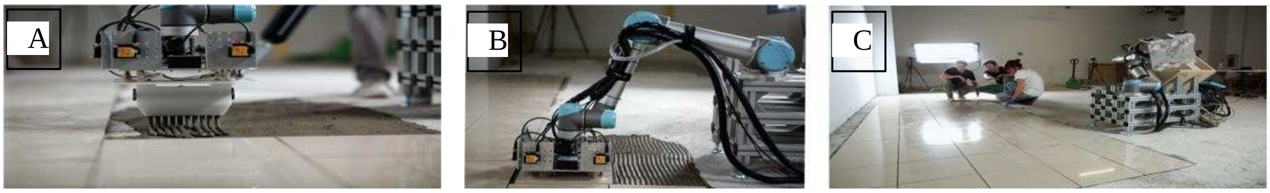

Fig. 22: tiles setting system A) mortar placement, B) tile placement; C) overview of the machine showing tiles placed (FCL, 2016).

The tile setting robot by Hazama and Komatsu consists of a tile setting unit, mortar storage and a gantry system for moving the tiles setting unit along the wall. The tile placement is done in vertical strips (fig.23), strip by strip and only an operator and worker are needed to set the system and prepare the wall for the process. However, the size of the tile is fixed (Bock & Linner, 2016a). Tokyu introduced a fully automated mobile platform system (fig.24) for installing ceiling panels with storage on board. Interior wall finishing can be performed using robots; wall plastering is done by semi-autonomous or assisting robot Anex (fig. 25) which only needs to be positioned by a worker. For fixing light fixtures and fittings, a mobile drilling robot by nlink (fig.26) is used which measures, marks and autonomously drills holes in the ceiling. The robot path

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

can be programmed using a BIM file with only manual positioning of the robot by the operator (Bock & Linner, 2016a). MIT developed an automated robot for the partition framing installation (fig.27). It has a storage area for the channels and an efficient manipulator. It consists of two systems; the trackbot for installing C-channels on ground and ceiling, and the studbot for installing studs (Bock & Linner, 2016a).

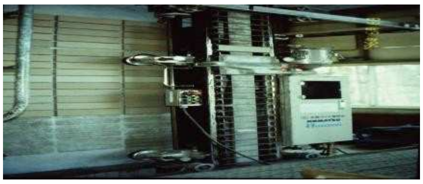

Fig. 23 (left): wall Tiling (Bock, 2016). Fig. 24 (middle): ceiling panel robot (Tokyu, 2016). Fig. 25 (right): wall plastering Robot (Anex, 2016)

7 CASE STUDY: FACULTY OF FINE ARTS BUILDING AT PHAROS UNIVERSITY CAMPUS, ALEXANDRIA, EGYPT

The case study illustrates the automation for the faculty of fine arts building at Pharos University in Alexandria. It is a horizontal building divided into three blocks, consisting of a basement, ground floor and seven levels (fig.28). The structural material is concrete and the building footprint area is 3,660 square meters. This case study provides a concept for automating the construction tasks of the building clarifying the changes that would take place in the construction materials to meet the robots' specifications. The facade (fig.29) includes glass panels, windows and a large mashrabiya which will be 3D printed offsite and assembled on-site.

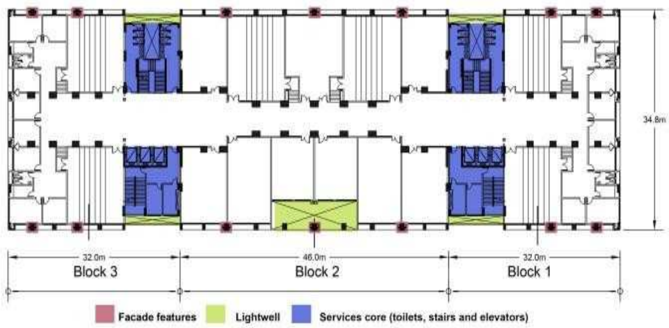

Fig. 28 (left): Building repeated floor plan showing zones (Researchers, 2021). Fig. 29 (right): Building main façade visualization (Youssri Azzam, 2019).

8 METHODOLOGY

This section presents the methodology applied to the case study of the educational building. It starts with the planning tasks and workers' shifts according to the pandemic's constraints and preparing a covid-19 work resume plan. Then performing a survey for tasks that require automation; to decrease on-site crew and time. And finally the development of a concept to apply automation on-site according to the pandemic's measures; starting from pre-construction phases and throughout the on-site tasks. Then a discussion is made to analyse the outcomes of the case study, the requirements to enhance automation application, and the challenges facing automated construction on-site.

8.1 Covid-19 work resume plan

The pandemic imposes changing the way construction projects are implemented starting from pre-construction phases. Social distancing and precautionary measures are a must to mitigate the pandemic effect. Working from home and coordinating through different platforms is one of the solutions to decrease congestion in offices and on-site. It saves time and improves coordination by synchronization of work and data. Virtual reality can be used for training on-site workers remotely. Planning of tasks and workforce would enhance the work sequence and avoid on-site congestion. Also, tasks should be ranked according to the degree of risk of each task and choosing a suitable solution. Some countries imposed preparing a site safety plan by the contractor identifying the necessary measures and precautions on-site, the site access, protective equipment provided, screening, facilities as well as isolation wards in case of infection. Relying on new construction techniques and off-site manufacturing is another solution to decrease time and replace the shortage of on-site workers. A summary for work resume solutions is shown in (fig.30).

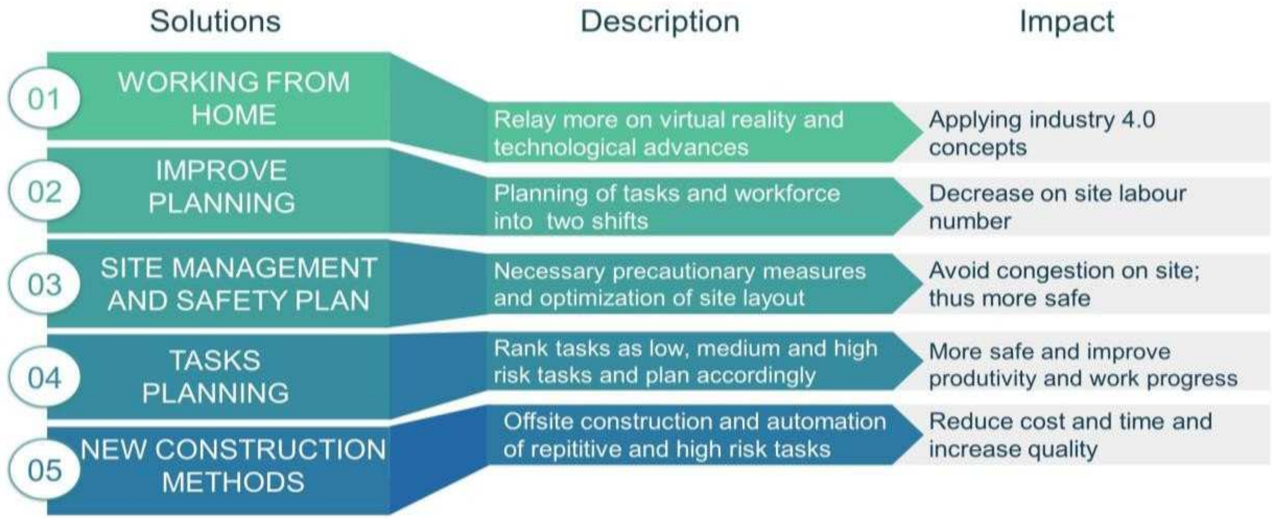

Fig. 30: Solutions for work resume on site and their impact (Researchers, 2021)

8.2 Survey for tasks which require automation

Construction tasks that have a priority for automation are tasks that require a large crew; hence it is a must to reduce on-site workers. Concrete work is an example as it involves several tasks from formwork preparation, reinforcement placement and concrete casting and finishing. Solutions for concrete work include prefabrication of concrete components off-site autonomously and only assembling them on site. Another solution is automation by using robots for each task of the conventional concrete tasks. Automation also involves 3D concrete printing which can be performed using fibre reinforced concrete; hence reducing the need for reinforcement or by placing reinforcement autonomously using robots. Façade finishing work is a high-risk task and accounts for several injuries; thus automation would be safer. Interior finishing tasks require automation as well since it is executed indoor which exposes the workers to the risk of infection.

8.3 Concept development

Applying automated construction during and after the pandemic involves several aspects (fig.31). It starts from the data gathering and work monitoring during construction. This involves construction methods and design requirements to apply automation efficiently. Robot oriented design is a must to adapt to working with robots and manipulators. The major problem during construction is to reduce on-site congestion. This can be achieved by reducing site visits and instead use drones to monitor work on-site. On working with prefabricated components, coordination between on-site construction and components delivery and storage on-site must be planned. BIM links all the phases from data gathering, designing, planning, scheduling to components fabrication and 3D printing industry. In case of limited storage area, the construction consolidation centres are used as it allows storing components in centres or warehouses and acts as a distribution facility and delivers them to the site on time for use without being stored on site.

Fig. 31: Automated construction 4.0 concepts (Researchers, 2021)

8.3.1 Site preparation phase

Excavation and site preparation tasks are executed using mature technologies with add-ons for autonomous operation (fig.4). Digging is done with Tokyu digging robot (fig.2) and excavation using Volvo excavation robot (fig.3).

8.3.2 Substructure work

The building's foundations are composed of piles and a raft foundation on top of the piles. The pile-driving process is performed using the pile driving machine fig. (5). The raft foundation is executed using Kajima's reinforcement positioning mobile robot (fig.6). While concrete casting is done using Kajima's rail-guided concrete distributor (fig.7). Concrete finishing work is executed using Fujita's (CALM) (fig.8).

Foundations walls are 3D concrete printed using Peri COBOD machine (fig.9). Reinforcement work is done by Kajima's reinforcement robot (fig.10).

8.3.3 Superstructure work

For decreasing on-site tasks, columns, beams, slabs and stairs are prefabricated and brought on-site for assembly after being stored in CCC due to the limited site area. The building structure is constructed in three phases, since it consists of three blocks. This in turn prevents congestion on-site. The slab type is precast hollow core slab. The Big canopy on-site factory (fig.11) is used for precast components handling and assembly. Then concrete grouting is done using the compact concrete distribution robot by Kajima (fig.12). The reinforced concrete cores are 3D printed using the COBOD printer (fig.9). The reinforcement is positioned using Takenaka's crane robot (fig.13). Brickwork is performed using SAM100 (fig.15) and fastbrick Hadrian system (fig.14).

8.3.4 Material handling

Obayashi's automated on-site delivery systems as well as Takenaka's unit are used on floors (fig.17 and 18). While Kajima's system is used for materials handling on the ground floor upon arrival on-site (fig.16).

8.3.5 Finishing work

Exterior finishing involves the installation of façade glass panels, painting work. Façade panels are installed using two robots depending on the panels' size. Kajima's system installed on the roof is used to assist workers in lifting large panels (fig.19). For small windows, Kajima's robot (fig.20) is used operating from inside the building. Façade painting is executed using Kajima's painting robot suspended from the roof (fig.21). Interior finishing involves tiles setting by FCL robot (fig.22), ceiling panels' installation by Tokyu mobile platform (fig.24) and installing partitions by studbot and trackbot (fig.27).

Wall plastering is done by Annex system (fig.25) and interior wall tiling by Hazama and Komatsu (fig.23). nLink robot is used for drilling holes in the ceiling for fixtures (fig.26).

8.4 Results and Discussion

The case study presented the application of single-task robots along with on-site factory to automate the construction of the educational building. This involves the use of construction 4.0 concepts to make work and coordination easier throughout the project's phases. The objective of the case study was to prove that automation is a safe solution for the pandemic restrictions without affecting work progress. This will be discussed in the following subsections.

8.4.1 Compliance with covid-19 restrictions

By applying automation, the reliance on on-site crew decreases significantly as almost every system requires a few workers; including the operator and one or two helpers in some operator assistance systems. Touchless equipment is an important requirement after the pandemic; thus autonomous systems are a good choice as they are remotely controlled or automated.

8.4.2 Productivity

Automation increases work productivity and decreases the overall schedule. It allows working continuously in two shifts and some systems can work for a full day. Some systems are used for various tasks by integrating different end-effectors; thus reducing the number of equipment used on-site and avoiding congestion. Automated systems allow performing tasks in parallel which cannot be achieved by traditional working methods due to the need to reduce on-site workers.

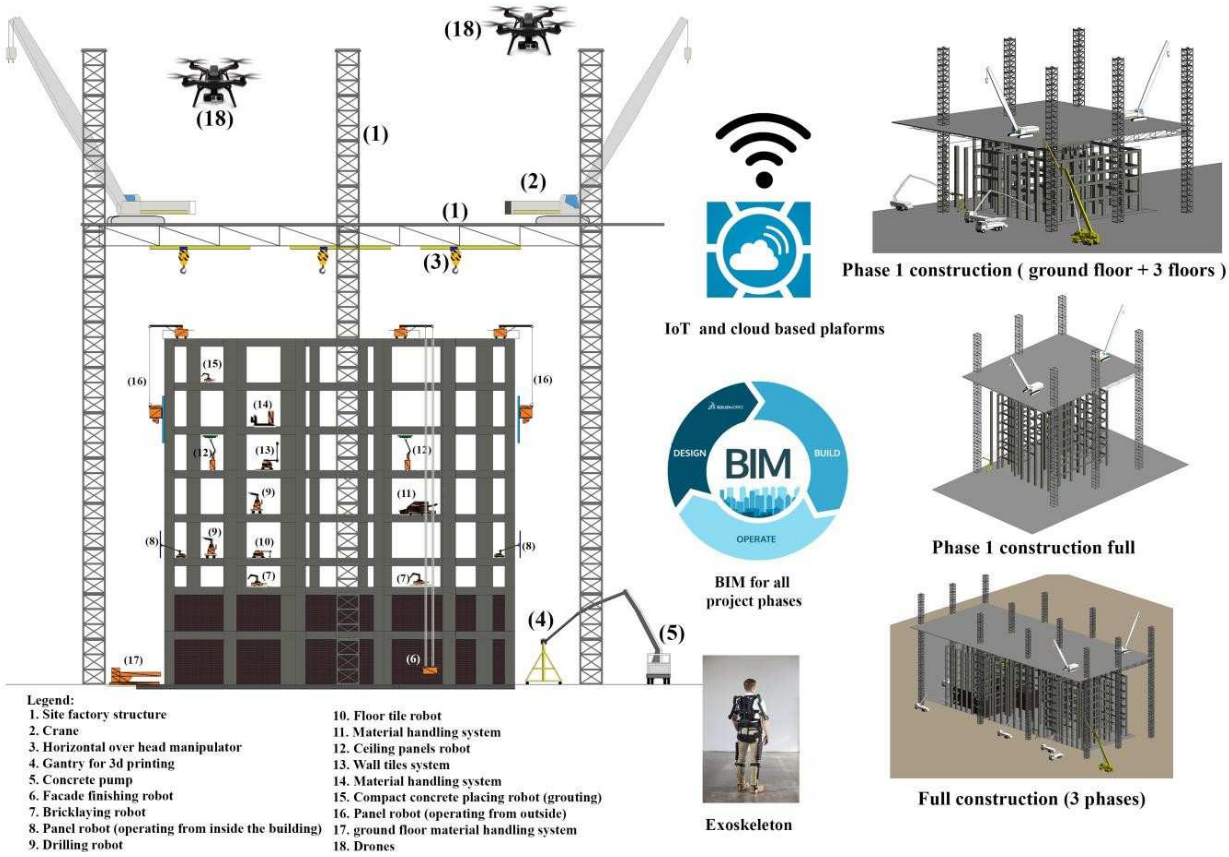

Fig. 32: Building construction progress, robots, systems and technologies used for automation (Researchers, 2021)

8.4.3 New technologies and design considerations

The potential of off-site manufacturing for high-order components as full detailed façade components, or full bathroom modules is expected to increase. Prefabrication of structural components is also gaining attention after the pandemic. This decreases the dependency on professionals to assemble them and allows automated assembly by on-site factories. 3D printing on-site saves time and allows customised designs without using scaffolding, also off-site 3D printing is efficient as it provides a variety of materials and prevents on-site congestion. IoT, connected devices and drones are essential for monitoring work, on-site workers and ensuring social distancing. A summary of the systems used in the case study are shown in (fig. 32)

With increasing automation levels, the design stages become more detailed and complex. The level of detailing increases to avoid errors during execution. To ensure good quality of the produced components, architecture design must cope with robot-oriented design to allow robotic assembly and integration of different systems in on-site factories. Design for assembly and disassembly are new emerging terms that decrease time and waste on-site during construction and deconstruction of buildings. Though the whole system seems more complex than the traditional construction methods, it can be divided into more simple sub-systems and components must be designed accordingly. On-site logistics and robots work cells must be well planned by an expert to avoid conflict between systems operating on-site floor by floor and phase by phase. Due to the lack of on-site storage and the nature of the site, CCC (construction consolidation centres) are used to supply components upon assembly; thus avoiding components damage or improper storage and congestion on-site.

8.4.4 Degrees of automation and construction workers condition

Automation levels vary from operator assistant to highly automated systems, however, full automation is still in the conceptual stage. Although automation decreases the reliance on on-site workers, it does not displace workers completely as automation starts gradually. This allows shifting workers to operators and supervisors on and off-site as well as helping in robotic assembly operations after proper training, so it does not cause unemployment. Due to the high cost of automated systems and shifting to automation, shifting is done gradually and for specific tasks depending on the project’s scale and location. In large scale projects, automation saves money for the contractor and provides high quality and decreases materials waste as well as labor insurance cost. However, in remote and uneven terrain sites, some automated solutions would be difficult to use and to set up routes required for their operation or even to ensure systems and workers safety.

8.4.5 Challenges facing automation application

The high initial cost of robotics and automated systems is among the major challenges facing its application. The lack of trained, educated workers who can deal with advanced technologies is another challenge. Laws and regulations are an obstacle for importing, implementing or manufacturing of advanced machines. The time required for setting up equipment must be considered to avoid delays in the project’s overall schedule. Drones operation must comply with the country’s regulations. The flight zone must be defined for the crew operating the drone showing potential hazards as power lines, high-traffic areas, or high structures and machines on-site which are higher than the drone potential. Coordination with filed crew and work scheduling and planning is necessary to avoid accidents on-site. The complexity of automated systems and their interference in small sites due to improper planning must also be considered.

9 CONCLUSION

Shifting to automated construction and coping with new technologies became essential. The pandemic affected the construction sector by delaying projects and causing financial problems; thus, it is considered a catalyst for automation. Automation of construction tasks and applying construction 4.0 concepts throughout all the project phases is a must to mitigate the pandemic’s effect. It helps decreasing on-site crew and replacing them with operators and helpers assisted by robots. However; in order to apply automation efficiently, planning of tasks and systems used must be considered. Proper planning for tasks, workers, and equipment plays a huge role in resource allocation, decreasing time and costs. Also, a robotics specialist must be involved in the planning of automated systems along with site logistics to ensure the integration of systems during operation. Prefabrication of structural components is expected to accelerate construction progress. 3D printing applications are expected to increase on-site for customized designs, and off-site for components in the facade. This in turn saves time, as only on-site assembly is required. Single task robots planning with on-site factory prevents congestion on-site or interference of systems. Robot-oriented design concepts allow components design for assembly and ensure components payloads according to the robots‘ specifications. However, automated systems and 3D printers’ costs would hinder using advanced technologies. Regulations and codes must be updated to allow using new technologies and importing them.

1 ABSTRACT

This paper aims to synthesize the results of the two-year experience in implementation of the decision support system for urban development. CRISALIDE project (City Replicable and Integrated Smart Actions Leading Innovation to Develop Urban Economies) started in October 2018 and was one of the very few projects financed between E.U. and Russian Federation through the ERA NET RUS PLUS (ENRP) program. It was also the only financed project in ENRP dealing with urban planning topics in this current E.U. programming period (2013-2020).

The project became possible due to the rising requests for innovations in urban life resulted in a noticeable shift in a political discourse towards the innovative ICT led economy, the new digital technologies, and the smart city policy in Russia. Though new initiatives seem too focused on technological solutions and lack a comprehensive understanding of smart development, they provoke the appearance of public discussions of the mentioned issues in cities, which themselves are the ecosystems for developing innovation. The missing components might be provided from the bottom level by using the place-based approach and implementing smart planning tools responding to the wicked local problems. This assumption lies in the basis of the CRISALIDE project aiming at bringing together technological, social, and organizational innovations.

CRISALIDE was experimenting in the Russian city Rostov-on-Don through a collaborative approach involving E.U. and Russian researchers, creating an innovative digital platform to facilitate the renewal and regeneration of brownfields. The first selected experimental field was the area of the old airport relocated outside of the city. Attracting notable attention of different local and regional actors due to its size, location, marketing potential, and regional significance, the selected brownfield helped involve local experts, activists, and policy-makers to develop an innovation tool and raise a public discussion on urban development. A series of consortium events, new collaborations, and discussions became essential for designing future development scenarios.

CRISALIDE system has an open, flexible structure based on urban ontology. It is a variant of artificial intelligence and will serve diverse issues in different cities. Oriented towards support in three main activities in urban development – new construction, reconstruction, and services provision – the system functions in three different modes. Three modes allow implementing required levels of public participation: from the internal communication within city administration to the public discussion involving all citizens.

Keywords: smart cities, planning for sustainable development, urban innovative inititiatives, urban policy design, DSS, Russia

2 INTRODUCTION: CONTEXT FOR INNOVATIONS

Recent numerous innovations introduced in urban planning are reflections on the fast development of GIS technologies, Big Data technologies, and smart city concept popularisation worldwide. Most of the countries are affected by these transformations, and the cities in different parts of the world become a testing ground for experimentations in applying new technologies in solving a variety of urban issues. Different tools and modeling approaches are being developed to support decision-making in urban planning (Leeuwen & Timmermans, 2006) based on land-use or movement simulation, virtual environment, or augmented reality.

In Russia, in recent years, a shift in a political discourse towards the innovative economy, new technologies, and smart cities solutions is noticeable (Batunova & Trukhachev, 2019) even though the interpretations of a smart city concept by different players depend very much on the field where they operate and focus mainly on the utilities' modernization and energy efficiency (Boykova, Ilina & Salazkin, 2016). This shift is happening on the transition from the administrative command economy to the neoliberal market, accompanied by the changing perception of urban planning.

After the long soviet period of the highly centralized planned economy, the socialist system collapsed, and the following 'no planning period, the state came back to the idea of the planning's necessity, and now it reopens urban planning in new conditions. The 'no planning period on the background of fast economic growth provoked many urban issues existing in the contemporary Russian cities, such as unplanned urban sprawl, chaotic land use, insufficient or ineffective transport, and engineering infrastructure. Urban planning legislation in new Russian history was created from zero (Golubchikov, 2004); it is still in the process of transition and is characterized by many shortcomings. At the same time, several new state initiatives influencing urban development are presented, among which a new housing strategy and two national priority projects – on the comfortable urban environment and smart cities. The smart city concept became an important political slogan in Russia, and the government announced the construction of 50 smart cities to 2025 (Batunova, e. & Trukhachev, 2019).

Innovations appear in many areas, including the integration of new information and communication technologies in the Russian administrative system and the evolution of the e-Government concept performed through three consecutive federal programs (Gritsenko & Zherebtsov, 2021). However, innovations in spatial planning during the same period can be likely associated with the new technologies and information systems implementation. Much less attention is paid to the managerial and policy innovations needed for a city to become smart (Taewoo&Pardo, 2011). Geoinformation systems in spatial planning, land use, or urban infrastructure are considered features of innovations, but in most cases, using new technological tools in urban planning and management does not necessarily lead to the changing approaches towards more progressive ones. Information systems serving to support decision-making processes in the creation of urban strategies and spatial development plans, the formulation of urban policies, the promotion of e-government, the management of urban infrastructures and housing stock or land use management in urban areas emerge as scattered fragments, which integration becomes even more difficult than in the 'pre-digital period'. Supporting decision-making is useless when decision-making lacks wisdom (Batunova, e. & Trukhachev, 2019).

The urban planning system and practices in Russia still have many attributes borrowed from the soviet past, such as centralization, bureaucratization and technocracy (Iyer, 2003), and institutional and social transformations are slow. It is especially evident in the low participation of non-government actors in urban planning decision-making and its weak impact. The new Urban Planning Code enacted in 2004 formally introduced such tools as public hearings that should serve as a tool for the people's involvement in the urban planning process, but in practice, this tool has minimal impact on the final decisions (Batunova et al., 2020). That also depends on the immaturity of the Russian civic society and little experience in public participation in urban development that has still been implementing through a top-down approach.

In such critical for introducing social and organizational innovations conditions, the CRISALIDE project aimed to build innovative solutions through a dialogue between local and international experts, different stakeholders, and actors. At the same time, it also had a practical goal: to develop a digital open and flexible platform as a tool to support the decision-making process in urban planning that would involve a wider range of actors in the decision-making process.

This paper represents the synthesis of the implementation of the decision support system for urban development in the Russian city Rostov-on-Don. It shortly describes the content of three main phases of the project: 1) inception phase: the evolution of the CRISALIDE's concept; 2) planning process activating period and boosting collaboration towards R&D in the involved Russian city; 3) final phase of the delivery of the innovative decision-making tool.

3 CRISALIDE: CONCEPT

The CRISALIDE project started with the idea to enhance the long-term collaboration in research and innovation among researchers, companies (technology providers), and the public sector through the design and implementation of a decision-making tool. The results and the impacts were organized in three innovation domains: 1) organizational innovation(such as new niches for the local, city-based private sector to boost R&D and innovation activities, policy impact to reinforce local and national related policies about collaboration in the field of R&D and innovation); 2) technological innovation and 3) social innovation (enhanced Local Identity to improve social capital, increased climate and environmental awareness to favor communities preparedness, increased ICT development awareness to enhance local economics).

The partnership constellation consists of 6 partners from 4 Era.Net Rus Plus call countries: Russia, Romania, Austria, Greece. CRISALIDE partnership comprised partners possessing relevant competencies to implement project activities and deliver valuable results:

(1) Private organizations skilled in territorial planning (at both local and regional level), as well as policy design - to provide expertise in integrated and sustainable urban and regional development, participatory planning processes and tools: Southern Urban Planning Center (Rostov-on-Don, Russia), URBASOFIA (Romania), CORP (Austria);

(2) Organisations with specific technical knowledge towards ICT systems and IGIS applications – to provide modern and updated technological solutions and digital services in the archaeological environment and ensure a homogeneous approach at consortium level: SPIIRAS (Russia), CORP (Austria);

(3) Organisations with specific knowledge in research and development – to support and coordinate research activities as well as territorial partners in implementing their activities at the local level: NIRD URBANINCEC (Romania) EMaTTech Forestry Department (Greece).

The inception phase was characterized by different analytical and cognitive activities and was realized through context research and innovative development schemes design. In this first step, different analysis methods applied research and knowledge transfer are pursued in the involved city to understand in deeper levelthe city context and achieve the set CRISLAIDE'S objectives.

From the beginning, a strategy of using a place-based approach and implementing solutions to specific planning tasks in the city was chosen, which allowed testing the product during the entire development and implementation process. This approach made it possible to apply the results of theoretical research in practice, to receive feedback from users, and, in turn, enrich theoretical work with empirical experience. When choosing a city for the project's implementation, the essential condition was such case characteristics that would allow further use of the results obtained in other cities. At the same time, the peculiarities of the city development had to form a set of conditions, on the basis of which a wide range of various planning tasks could be formulated, in support of solutions for which the decision-making support system could be tested.

For the realization, the city of Rostov-on-Don, with a population of 1,130,305 people, was selected. Rostov-on-Don is the capital of the Rostov region in Southern Russia and the administrative center of the Southern Federal District. The city is in 10th place out of 1,113 cities of the Russian Federation in terms of population, and its metropolitan area has a population of about 2.16 million people. Rostov actively participates in all national programs and projects. In 2018 the city became one of 36 pilot cities defined in the priority project ‚Smart city 'as municipalities, where Smart City technologies will be introduced.

4 CRISALIDE: PARTICIPATION PROCESS

The planning process and activating – IUP (Innovative Urban Projection) – phase designed and structured the IDSs (innovative development schemes) through participatory workshops. The innovative development schemes were developed together with the key local actors and experts in the selected city Rostov-on-Don. The Innovative Urban Projection stage methods used:

- the local planning process, co-design of IDS through organized events (the organization of workshops in order to assess local urban issues and their solutions through application of ground-breaking planning tools and/or innovative technologies, held by experts);

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

- co-design process for the collaborative platform (technical partner together with experts developed the innovative decision-making tool based on the developed IDSs);
- Assessment of the achievements of the workshops prioritization of selected projects promoting innovation and definition of the roadmap for implementation and sustainable maintenance.

The experimental site selected for the CRISALIDE project implementation was the area of the former airport 'Rostov-on-Don' located in the eastern part of the city in nine kilometers from the city center Pervomaysky administrative district. It was defined after the detailed analysis of the existing brownfields within the city borders, the approved city strategy and general plan, and negotiations with the local authority (Fig.1). The airport stopped its operation in December 2017, when the new international airport opened - Platov International Airport. The local planning documents consider the old airport's territory as an internal spatial resource for development years before the actual realization. Thus, the city's General plan approved in 2015 proposed the construction of 1,596 thousand square meters of housing within the plot of 267 ha until 2035. After the new airport construction, the local authority started to promote the area for redevelopment, and several projects have been done, one of which was presented at the Russian Investment Forum in Sochi in 2018.

Fig. 1: Location of potential sites for redevelopment on the territory of Rostov-on-Don.

In the local planning documents, the old airport's territory was considered an internal spatial resource for development also long before the actual implementation of the airport relocation. Thus, the city's General Plan approved in 2015 provided the old airport area to construct 1,596 thousand square meters of housing until 2035. The draft Strategy of Social and Economic Development of Rostov-on-Don defined this area to form a new sizeable multifunctional district: multi- and mid-rise residential buildings, public and business zones, infrastructure development.

The CRISALIDE project was aimed at enhancing bottom-up participation in the urban development process. Research on participation design processes distinguishes four levels of influential participation: communication, consultation, collaboration, and empowerment (Stelzle & Noenning, 2019), and the CRISALIDE focused primarily on the second and third levels of influencer engagement - consultation and collaboration – with the goal of achieving long-term research and innovation collaborations between developers, researchers, technology providers, and the public sector. Through the selection of an experimental area that is an essential site for different types of local stakeholders – authorities, business, or public representatives – CRISALIDE created conditions for the collaborations and public discussions of the area's future (Batunova et al., 2020). It was reached through the organization of the design workshop that is, according to Müller (2003), a kind of "third space" in which different parties communicate with each other in an unfamiliar environment and must create shared knowledge and even the processes of developing this common knowledge. Exploring this "third space" through collaborative design helps build the capacity of both users and developers. Capacity building is the various aspects of the will, knowledge, skills, partnerships, resources, infrastructure, and leadership needed to enhance the ability to plan, implement, evaluate and sustain efforts

From 14 to 18 June 2019, four partners of the CRISALIDE consortium - Southern Urban Planning Center (Rostov-on-Don, Russia), Urbasofia (Bucharest, Romania), NIRD UBANINCERC (Bucharest, Romania), CORP (Vienna, Austria), as well as participants of the project SPIIRAN-Scientific and Technical Bureau of High Technologies (St. Petersburg, Russia) and the Southern Federal University (Rostov-on-Don, Russia) held a one-week workshop on the topic "Redevelopment of urban areas" with the participation of representatives of the State Duma of the Russian Federation, Rostov-on-Don City Duma, Administration of the Rostov Region and Rostov-on-Don municipality, the Chamber of Commerce and Industry of the Rostov Region, developers, public organizations, architects, urbanists and ecologists of Rostov-on-Don. The event was held in the main building of the Southern Federal University in Rostov-on-Don. The workshop consisted of six thematic three-hour sessions with the participation of local experts and the final seventh session with the participation of the consortium partners. More than 30 experts and specialists of various profiles took part in the event (Driedger et al., 2007).

The participatory workshop was organized with a dual purpose: 1) to lay the foundation for the design of a decision support system by mapping existing knowledge and collecting justifications and 2) to develop technical and local requirements for an innovative decision-making tool. Thus, based on a set of key performance indicators (KPIs) that have been discussed and agreed upon with a multi-stakeholder group, the system will provide decision-makers with a set of values based on smart decisions and a comprehensive quality of life formed in the process of urban redevelopment.

The workshop methodology was developed by partner Urbasofia (Bucharest, Romania) and was clearly linked to the collaborative design cycle, which includes the following steps:

- identification of (local) problems and needs in relation to (global) problems;
- mapping of relevant stakeholders;
- collection of evidence (collection of relevant data);
- identification/mapping of resources (opportunities and threats);
- determination of expected results;
- idea generation (collective brainstorming);
- definition of actions (prioritization of actions);
- appraisal.

The workshop "Redevelopment of Urban Areas" held in Rostov-on-Don confirmed the correct choice of the approach to the joint design of the decision support system and made a significant contribution to the formation of the substantive part of the decision support system in the field of urban planning. The CRISALIDE project created an opportunity to enhance dialogue between public and local authorities and integrate bottom-up initiatives into the local decision-making system. The practice of public involvement at the pre-design stage is uncommon in Russian cities. It, therefore, is an innovation that allowed consolidating public opinion, taking into account the various interests of the present and future periods, including most effective local development resources in the use and launch processes at the local level that activates socio-economic development (Batunova et al., 2020).

5 CRISALIDE: IMPLEMENTATION

The third implementation phase focused on increasing the capacity of local actors through the implementation of the innovative decision-making tool.

The system of intelligent decision-making support for urban environment management is primarily intended for the integration of decision-making processes in the field of creating urban strategies and spatial development plans, formulating urban policy, promoting e-government, managing urban infrastructures and housing stock, retraining production areas and their development (science parks, incubators, a network of clusters of small and medium-sized enterprises). CRISALIDE's innovative decision-making tool is a software and hardware complex based on intelligent GIS (IGIS). IGIS provides the ability to integrate maps of various formats, implement a scenario approach in urban development modeling, 3D modeling, support for 2D modeling, support decision-making based on expert knowledge, monitor changes and assess the possible impact of decisions on the development of the urban environment.

CRISALIDE system designed as an open, flexible structure based on urban ontology. It is a variant of artificial intelligence that will be able to serve diverse issues in different cities. The system is based on a digital model of the city, created by the project team on the basis of the urban ontology developed during the first stage of the project. Ontology in information technology is understood as a description of the subject area using a conceptual scheme (Fig.2). A conceptual schemy is a data structure containing all relevant classes of objects, their relationships, and rules (axioms, restrictions) adopted in the area under consideration (Sowa, 1995).

Among the advantages of using ontologies to represent a model of the urban environment, the following should be noted:

- consistency: ontology presents a holistic view of the urban environment as a subject area;
- uniformity: the material presented in a single form is much better perceived and reproduced;
- scientific nature: the construction of an ontology allows you to restore the missing logical connections in their entirety.

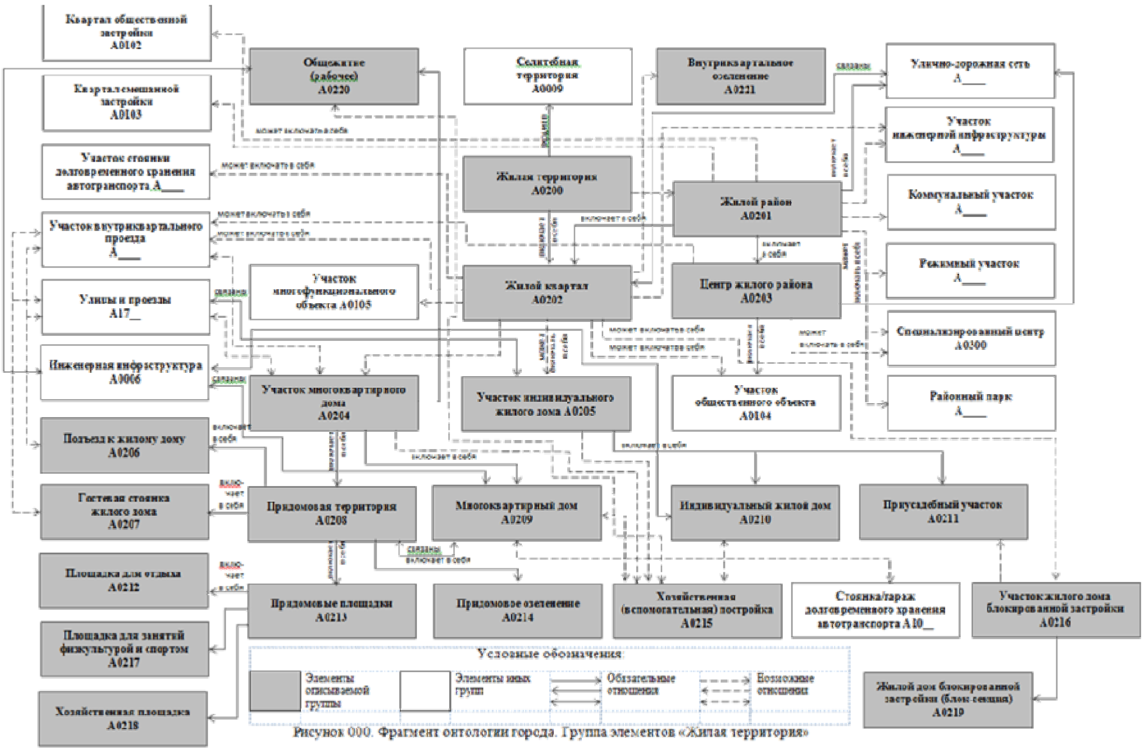

Fig. 2: The fragment of city ontology. The group of the elements' Residential area'.

The developed for the CRISALIDE system ontology proceeds from the division of the city into four main subsystems: spatial, economic, ecological, and social. The urban ontology is a description of the main entities of the subject area with which an expert (knowledge specialist) works in urban development. The ontology consists of classes describing basic concepts (for example, School, Kindergarten, Shopping Center, etc.) and ontology objects related to specific schools or kindergartens (for example, kindergarten № 5). Each ontology object has properties that allow it to be used for solving computational problems; the ontology object takes the set of properties itself from the class, and each object has its own values. Also, ontology objects have connections with other objects, which allows applying various methods of logical inference. The system allows supplementing and editing the ontology based on expert opinion, adapting it to specific tasks. Editing of ontology objects occurs centrally from the ontology editor without using inconvenient and often complex tools for working with databases (or files) directly

Oriented towards support in three main activities in urban development – new construction, reconstruction, and services provision – the CRISALIDE system functions in three different modes. Three modes allow implementing required levels of public participation: from the internal communication within city administration to the public discussion involving all citizens (see Fig.3). Those three modes were defined during the participatory design process described in the previous chapter.

The first mode of functioning that had been implemented during the development period is the PROFESSIONAL MODE. This mode is oriented to the internal use of the tool within the city administration and involves the participation of a decision-maker and a professional analyst working in the structure of the Administration. In this simple scheme, a decision-maker gives the task to a professional analyst who works within the system requesting, if necessary, additional data from different departments of the Administration and information systems if the CRISALIDE database does not contain the necessary information.

The second mode of functioning is the EXPERT MODE which is planned to be developed at the next stage of the system's implementation. This mode implies the involvement of the expert community in the decision-making process. The experts in this mode can formulate the issues themselves; they can detail the requirements for the issues' solutions to change the calculated coefficients. They are provided with a private chat for communication.

In the final version of the system, the third, PUBLIC MODE, will be implemented. It should be realized based on a web portal, where everyone can have access. Citizens can express their proposals on the issues solving, and they can model the parameters of the urban planning solutions. The best (from the point of view of the system) solutions can be displayed on the portal

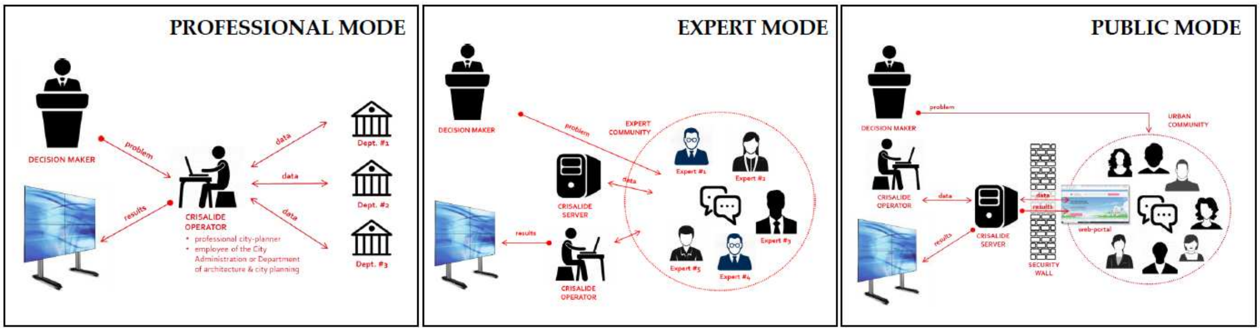

Fig. 3: Three modes of the CRISALIDE system operation.

The operation within the system differs according to three main processes in urban development in which the decision-making support should be realized: new construction, reconstruction, and services provision. Fig.4 demonstrates an operational model for the 'new construction' task.

Depending on the task, the CRISALIDE system proposes different algorithms in new construction, redevelopment, or assessment of services provision. All algorithms include three main phases: data imput, modeling, and results presentation.

Unfortunately, the pandemic situation created obstacles and slowed down the process of the implementation: the final steps, including system testing and assessment, should still be realized. However, the system has been registered in the Russian Federal service for intellectual property and received a patent.

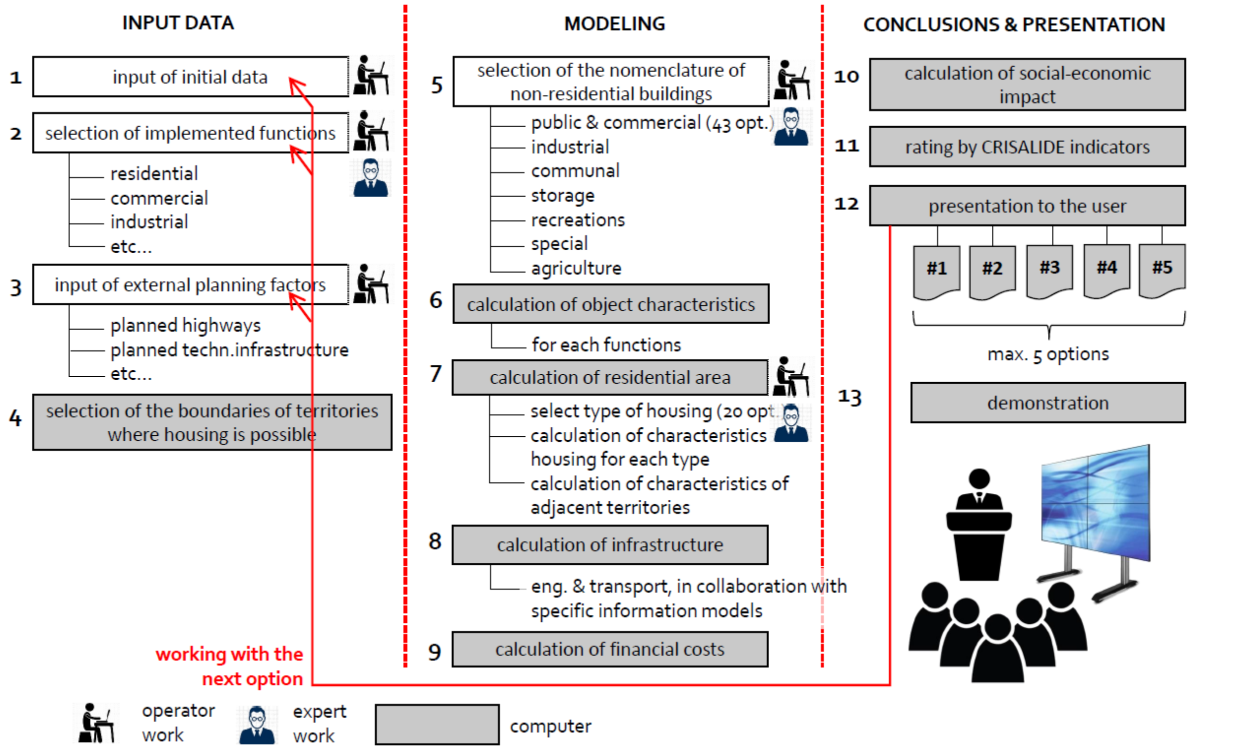

Fig. 4: Example of the operational model for the new construction.

6 CONCLUSION

The contemporary transformations of the Russian national policy brought to life the development of a smart city concept in Russian cities, which is still in a very initial stage but became a driver for the numerous initiatives in this field. CRISALIDE project (City Replicable and Integrated Smart Actions Leading Innovation to Develop Urban Economies), being of such initiatives, became one of the very few projects financed between E.U. and Russian Federation through the ERA-NET RUS PLUS (ENRP) program and the only financed project in ENRP dealing with topics related to urban planning in this current E.U. programming period (2013-2020).

The CRISALIDE project used a way of working on the cities that is very distant from the ordinary practices operated in Russia, building the solutions from the bottom, working with the stakeholders in identifying the problems to be faced, and defining the figure of the planner as that of a mediator and facilitator of complex processes. The CRISALIDE project, being oriented to developing an innovative digital platform, created an opportunity to introduce social and organizational innovations in urban planning through a participatory bottom-up approach. The digital dimension is an arrival point of an actual participatory planning process (Elisei, Batunova & Draghia, 2019).

Experimenting with the first selected experimental field – the area of the old airport relocated outside of the city – the project involved local experts, activists, and policy-makers in developing an innovation tool and raising a public discussion on urban development. A series of consortium events, new collaborations, and discussions became essential for designing future development scenarios.

The central part of the CRISALIDE innovative decision-making tool is a knowledge base that includes a set of ontologies describing objects of the urban environment and the relationship between them (such as transport infrastructure, engineering communications, residential areas ore public areas). Another component of the knowledge base used is a set of objects - elements of the urban environment.

Designed as an open, flexible structure based on urban ontology, the CRISALIDE innovative decision-making tool is oriented to integrate decision-making processes in the field of creating urban strategies and spatial development plans, formulating urban policy, promoting e-government, managing urban infrastructures and housing stock (facilities and utilities, regenerating residential areas), re-qualifying productive areas (renovation former industrial zones, temporary use of vacant buildings) and their development (science parks, incubators, a network of clusters of small and medium enterprises), as well as land use management in urban development areas.

7 ACKNOWLEDGEMENTS

This paper is based on the project "CRISALIDE: City Replicable and Integrated Smart Actions Leading Innovation to Develop Urban Economies", the winner of a joint Russian-European competition of innovative projects under the ERA.NET-RUS PLUS program (project no.42016, application ERA-RUS-4188).

The implementation of the CRISALIDE innovative project is funded by the The Foundation for Assistance to Small Innovative Enterprises in Science and Technology (FASIE) [grant number 395ГР/42016].

1 ABSTRACT

Despite various measures to promote cycling, the overall proportion of journeys taken by bike in Austria has improved only slightly in recent years. As part of its mobility strategy, the Austrian Federal Government has set itself the target of doubling the proportion of journeys taken by bike in in 7 years. To this end, motivational or behavioural approaches should be preferred to costly infrastructural measures. In this context mobile apps for tracking but also for monetising users' own data – as a technological manifestation of the "quantified self" – are developing rapidly. Sweepstakes and even performance-related rewards are booming in many areas. At the same time, however, there is increasing awareness of data protection in Europe. In this respect, blockchain technology has great potential for handling user data due to its decentralisation, transparency and security (Buhl et al., 2017). Applications on the blockchain are disruptive innovators for a wide range of applications, from transaction processing to land register entries to logistics chains. In all these, data can be stored using decentralised, unforgeable blockchain records (Hopf & Picot, 2017). Applying such innovative measures can also support cycling promotion with all its associated benefits in reduced emissions, positive health effects and reduced infrastructural costs.

The solution envisaged in the project reward cyclists for regular cycling with so-called "Cycle Tokens". The key technologies – machine learning and blockchain – present an innovative solution for the validation of routing data and transaction processing. As proof of concept, it is tested whether and how a safe and transparent process of value generation for regular cycling can be created via a utility token, to translate the macroeconomic effects of cycling into value units.

Keywords: Machine Learning, Blockchain, Cycling, Gamification, Nice Rides

2 INTRODUCTION

Ten years ago at the peak of the gamification hype, the research project "Nice Rides" targeted the promotion of bike commuting in the (sub-) urban area. While the primary goal was to implement a new routing algorithm allowing the choice between safe, time efficient and attractive routes, Nice Rides integrated a motivational framework with gamified elements to achieve a change in long established behavioural patterns (i.e. not choosing the car for commuting). The target group was directly involved in the design of the gamification framework as well as in the optimisation of the routing algorithm regarding the safety and attractiveness of bike routes. Users were encouraged to rate junction points and cycling pathways on an interactive map running on mobile and desktop clients. The gamification framework implemented mechanics like points, achievements and challenges such as "Cycle2Free" – thus enabling users to unlock premium features of the Bike Citizens app. Ten years on from Nice Rides we are working on the next iteration of a tokenised incentive model for sustainable mobility. In Cycle4Value, a transparent and low-threshold reward model for promoting cycling based on blockchain technologies is currently being tested in practice. The economic, health and ecological benefits/effects of cycling are presented simply and, after a plausibility check using machine learning, converted into a real value (Cycle Tokens). These value units are stored in a digital wallet and can be remunerated in a test marketplace. The research project surpasses conventional incentive systems because, on the one hand, both the storage of the value units and the redemption process are decentralised, tamper-proof and transparent and, on the other hand, the real economic benefit of active cycling is fairly monetised.

2.1 Practical Background

Despite various measures to promote cycling, the overall share of journeys made by bicycle in Austria has changed only slightly in recent years (Tomschy and Steinacher, 2017; Illek and Mayer, 2013). In line with its mobility strategy, the Austrian federal government aims to double the share of journeys made by bicycle in seven years. In addition to infrastructure, motivational and behavioural approaches in combination with technological innovations play a central role in achieving this ambitious goal. The positive effects of cycling on a collective and individual level (e.g. reduction of air and noise pollution, reduced land use, health-promotion, improved and socially just mobility), especially when substituting car journeys, have been proven in numerous studies (Bracher et al., 2002; Macdonald, 2007; Schäfer and Walther, 2008; Litman, 2003). Cost-benefit analyses, among others, proved to be a promising approach to quantify the ecological, economic, health and traffic benefits of cycling. While there are various incentive approaches to promote cycling, which primarily pursue an event character and are based on the distribution of prizes, Bike Citizens has already taken the first step towards a performance-based bike currency (Finneros) in the course of the research project Nice Rides. However, a transparent and tamper-proof solution for validation, storage and redemption has not yet been implemented. This is where the Cycle4Value framework comes into play, by utilising machine learning and blockchain technologies.

2.2 Motivational Framework

Cycle4Value develops and evaluates a blockchain-based incentive system, based on complementary integration of the transtheoretical model (Prochaska et al., 2009). In order to change human behaviour, it is necessary to understand the underlying behavioural processes. Many theories of motivational psychology and behavioural science have attempted to describe and explain mobility behaviour, including the theory of planned behaviour (Fishbein and Ajzen, 1975), the norm-activation theory (De Groot and Steg, 2009) and the self-regulation theory (Bamberg et al., 2011). In line with (Prochaska et al., 2009), the self-regulation model (Bamberg et al., 2011) claims that behaviour changes through a time-ordered sequence of stages, each stage involving various cognitive and motivational difficulties.

Within our motivational framework monetarised incentives will be triggered using smart contracts powered by the Blockchain as a Service (BaaS) platform Ardor. By providing information and action-related knowledge (Staats et al., 2004), setting goals (Locke and Latham, 2002), comparison and competition with other users, and rewards and feedback (Fujii and Mackey, 2009; Froehlich, 2011), mobility behavior is influenced in a targeted, playful manner. In addition, incentives enhance behavioural control and support positive aspects of eco-mobility (Ajzen and Manstead, 2007). The major advantage of this token-based incentive system is that the individual interventions are fed directly to individual users, increasing motivation and the likelihood of voluntary and longer-term behavior change. The main goal is to achieve a change in established behavioural patterns by encouraging positive attitudes and awareness regarding the economic, ecological and health-related effects of cycling. Through the integration of modern ICT technologies such as a token-based incentive system and plausibility algorithms supported by artificial intelligence and machine learning, target groups will be rewarded with Euro pegged utility tokens for participating in field tests in Vienna, Graz and Krems (Austria) as well as Berlin (Germany). Based on a meta-analysis, the value for each token is defined as 1.37 Euro per kilometre (more details can be found on https://www.cycle4value.at and in our previous paper (Seewald et al., 2021).

2.3 Blockchain Technology

(Pfeiffer et al., 2020) show that blockchain technologies are a valid way to secure gamification frameworks and their ecosystems. The authors also provide insights into innovative consensus algorithms and their vital ability to monitor multi-chain processes. In this context (Komiya and Nakajima, 2019) examine consensus algorithms as a reward system. They introduce their Proof-of-Achievement (PoA) approach, an algorithm optimized for blockchain games which focusses on the number of tasks achieved in the game. Similarly, (Yuen et al., 2019) perceive consensus algorithms like Proof-of-Work (PoW) as a bottleneck for games. Their proposal is called Proof-of-Play with a focus on peer-to-peer solutions. Along with Proof of Stake (PoS) as the consensus algorithm featured by Ardor, an environmentally friendly consensus method is used within Cycle4Value to verify all transactions, while at the same time ensuring connectivity to ERC20 protocols. When using PoS a mixture of volume (stake), online time and random components determines whether a node validates transactions. This makes it possible to operate the blockchain in a more energy-efficient way. In fact, a Raspberry Pi Zero is enough to operate a node in the network.

2.4 Cryptoeconomics

Cryptoeconomics is an emerging field of economic coordination games in cryptographically secured peer-to peer networks (Voshmgir and Zargham, 2020). This field was bootstrapped following the appearance and popularisation of the Bitcoin network, which runs a protocol for a Peer-to-Peer Electronic Cash System (Nakamoto, 2019). Transactions in the Bitcoin network are based on a newly created unit of account inherent to the protocol and governed by a set of simple and deterministic rules. The detachment of this unit account from anything outside of the system and its rigid issuance policy led to the creation of a digital token, the value of which – when denominated in a commonly used unit of account like the e – is very volatile, with swings of sometimes more than 10% per day. The volatility of Bitcoin and many digital assets which followed led to a widespread belief that this characteristic is inherent to digital assets based on cryptoeconomic protocols. This is however not the case, as the emergence of stable coins such as Bank (2019) showed. The Ethereum protocol, first described in a 2014 whitepaper (Buterin et al., 2014), popularised the idea of cryptoeconomic systems with support for fully programmable smart contracts. This led to a plethora of innovations in the digital assets space and inspired the idea of mapping the economic benefits of cycling to such a digital asset.

One important consideration for such a token-based incentive system which rewards cyclists with theoretically cash-equivalent tokens is, of course, fraud. Especially for large stakeholders like cities, it is very important that incentives not be misallocated as otherwise the expected benefits may not materialise. In fact, one of the main obstacles to wide distribution of such incentive systems is exactly this capacity for fraud, and large stakeholders have taken this issue as an argument against the wide deployment of such systems. We will describe our approaches to deal with this issue in section 3.4.

3 METHOD

3.1 Research Questions

The primary aim of the Cycle4Value research project is to increase the awareness of the positive effects of cycling, the acceptance of cycling as a means of mobility and the implementation of cycling as a habit, which will primarily support the subsequent ambitious transport and health policy strategies.

The research questions are as follows:

(1) Is a tokenised incentive framework able to alter attitudes towards cycling and improve awareness of the positive effects, as well as alter behaviour (cycling as a habit)?

(2) Do users and stakeholders see the monetised value of cycling as a fair reward?

(3) Can the legacy ad-hoc plausibility model of the Bike Citizens Beta App be replaced by a machine learning system trained on similar data?

(4) Can the legacy ad-hoc plausibility model of the Bike Citizens Beta App be replaced by a pre-trained transport-mode-detection model?

(5) Can such a system be made and kept cheat-proof indefinitely by leveraging artificial intelligence and machine learning techniques, as well as continuous retraining?

(6) Can such a system be made and kept cheat-proof more simply (using captchas or similar techniques), by preventing automated generation of large numbers of accounts by bots?

(7) How can cheating detection techniques be improved "on the ground", when it is unlikely that ground truth data on cheating techniques is available in a timely manner (excepting deliberate challenges to the user base)?

Research questions (1) and (2) are addressed within this paper (e.g. in Section 3.1); (3) and (4) were already addressed in (Seewald et al., 2021) and will be summarized and slightly extended in Sections 2.4 and 3.2; (5), (6), (7) will be only partially addressed here and are to some extent left open for future work as a definitive evaluation is not yet possible within our project.

3.2 Research Material

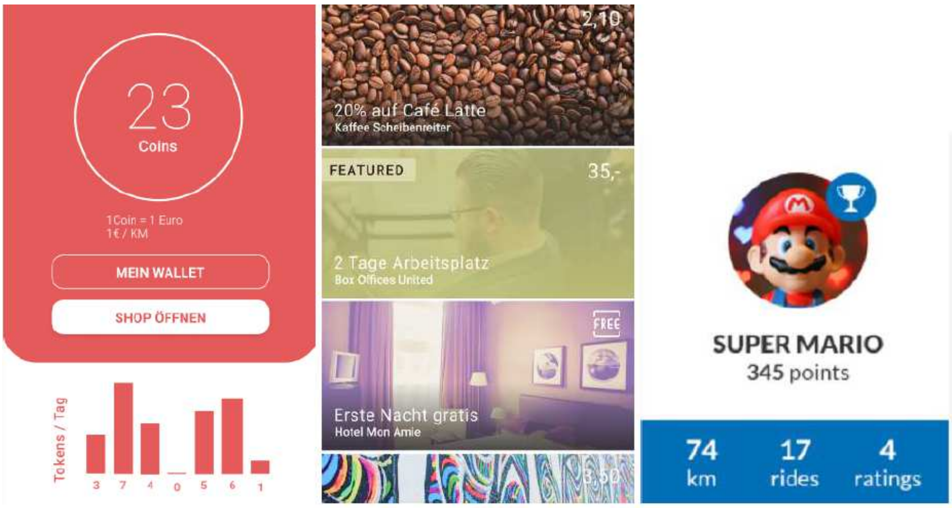

Fig. 1: Left, Centre: Cycle4Value dashboard and marketplace; Right: Nice Rides dashboard.

The Bike Citizens Beta App, which has been extended by new features in relation to the token-based reward system, serves as the object of investigation. During the beta test, aspects of usability and acceptance by users and stakeholders were surveyed by means of an online questionnaire. In addition, users were recruited from the Bike Citizens network to actively try to outsmart the existing routing algorithm. After a previous marking, recorded tracks are marked as fake tracks. Figure 1 show the Cycle4Value dashboard as well as the marketplace, and on the right the dashboard that was implemented in Nice Rides. While we are currently pursuing the token-based reward approach, the previous project relied heavily on established gamification elements such as points – the so-called “bike impact score”, badges and challenges.

3.3 Framework

Figure 2 shows the incentivisation approach followed in Cycle4Value. Where Nice Rides used an abstract point system including digital badges, in Cycle4Value every kilometre cycled is converted into a cycle token, based on a formula that considers individual and collective benefits of cycling. Before being transferred to a digital wallet, the registered route data is checked for plausibility using machine learning. The wallet serves as a frontend, where the user can view the current status at any time. The Cycle Tokens earned in this way serve as vouchers for a marketplace supplied with incentives from various partners such as shops, public transport providers and cultural institutions.

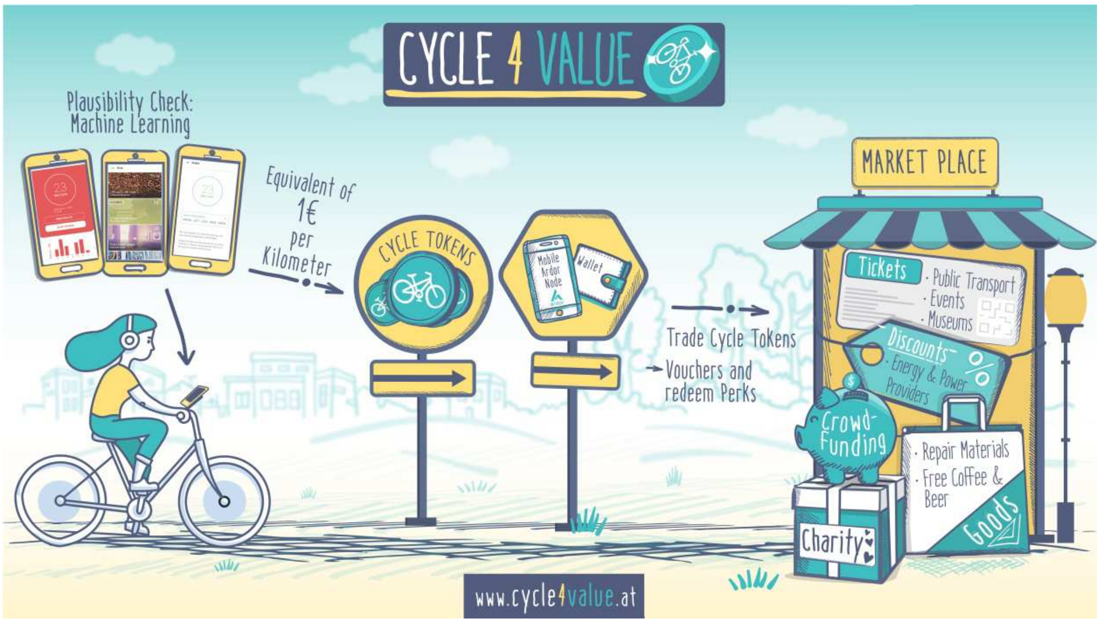

Fig. 2: Incentivisation approach followed in Cycle4Value

3.4 Cheat Proofing

To investigate cheating and fraud detection – and thus cheat-proof the system – we previously analysed an existing ad-hoc legacy system which tests for the related concept of track-based cycling plausibility – created mainly to prevent people uploading noncycling tracks. In (Seewald et al., 2021), we have shown that the results of a legacy model for plausibility detection of cycling tracks can to a moderate extent be reconstructed by a classically trained rule-learning model with handcrafted features, as well as to a somewhat lesser extent by a pretrained transport mode detection (TMD) model, even though the latter was trained on a completely different dataset.

To better compare both measures, we split the original plausibility values of 0-100 into five (almost) equally large intervals: [0;20); [20;40); [40;60); [60;80); [80;100] and computed arithmetic mean and standard deviation of the new plausibility measure over each interval. Fig 3 shows the results, and the same values averaged for each possible legacy model plausibility as a Raw Mean. The latter roughly corresponds to a ROC curve. The mean TMD-derived plausibility measure increases strictly monotonically from the lowest to the highest interval. Although standard deviation is initially high, it shrinks for higher intervals. A recalibration of the TMD model or an adaptation of the threshold for plausibility could improve the match considerably. The Pearson’s correlation coefficient between legacy and TMD measure is 0.31, indicating a weak to moderate correlation. Note again that the TMD model has not been trained on any part of our datasets, so these results are quite surprising and indicate that TMD models are a good starting point for a trainable plausibility – and possibly also cheating – detection system. Note also that the legacy model was not explicitly designed to detect cheating and fraud, but rather to increase the quality of uploaded data by ensuring that only bicycle tracks were accepted. We are currently improving on this work to build the final track-level fraud detection system.

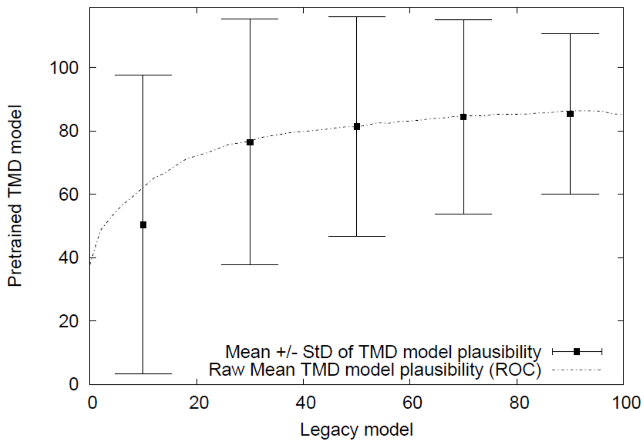

Fig. 3: Comparison of the ad-hoc plausibility (legacy) model with transport-mode detection (TMD) model.

However, as will be seen later in section 4.2 not all types of fraud are detectable at track-level. We also have to consider attacks involving multiple tracks, such as using multiple phones on a single bike, which can only be detected at multiple-track level. It is necessary to build a multiple-track-level fraud detection system as well.

4 RESULTS

4.1 Expert Survey

14 experts from the city administration, technical universities and transport planning took part in an online survey. 37% of the participants considered gamification to be “over”, and alternative incentivisation approaches as preferable when promoting cycling. Vouchers, giveaways and initiatives such as “Cycle2Work” were given as examples. None of the stakeholders currently use a blockchain-based incentive system. Regarding the value of a cycled kilometre as basis for a cycle token, values between 0.26 and 0.5 Euro were seen as most appropriate (57%) followed by 0.51-0.75 Euro (29%). Considering that the sum of 1.37 Euro as derived in Cycle4Value includes both individual and collective benefits, there is a good match with this expert view, if 50% of the value is granted to the user and eligible for collecting rewards (= 0.68

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Euro which take into account the collective benefit). In terms of the positive impact of cycling, the greatest relevance was attributed to environmental benefits (67%). However, the meta-analysis carried out showed that the greatest benefit actually comes from health-related effects, although the ratio can shift flexibly depending on the CO2 price per ton. 83% see the incentive system as valid means to promote cycling.

4.2 Cheating and Attack Modes

The semi-monetary compensation in form of tokens which are potentially convertible to cash makes cheating the system (respectively fraud) much more likely. While the number of false negatives (Type II errors, undetected cheaters) should be small, the number of false positives (Type I errors, i.e. people wrongly classified as cheaters) should also be small to prevent disillusionment and reduced trust in the reward system. To some extent this can be optimised by using learning algorithms that output confidence values and by choosing appropriate thresholds. In our latest model, the number of tokens generated corresponds to the square root of cycling kilometres per track and is cut-off at two levels: at most 4 tokens per track, and at most 8 tokens per day, yielding some buffer against attacks by limiting payoff for a single user. However as this is probably not sufficient, we have collected six types of possible attacks on the system. This list may be of course be incomplete and is intended only as a starting point.

(1) Uploading tracks from sports events (e.g. cycle racing)

(2) Uploading tracks from delivery services

(3) Uploading tracks made with other vehicles (may include e-bikes)

(4) Using more than one phone on a bicycle

(5) Uploading automatically generated fake tracks

(6) Uploading modified real-life tracks

Attacks (1), (2) and (3) are not a large problem. In (1), the restriction of the maximum number of tokens per track and day – mentioned above – severely restricts the possible gain per user. (2) should not yield any payoff as these bike rides would happen anyway even without incentives. However if only a single person profits, it remains a minor problem. We could address it by either filtering out common bike routes which

could be applied to attack (1), should too many similar tracks be uploaded. Attack (3) should be easily detectable by the fraud detection system although the differentiation of e-bikes is still an open problem.

The more interesting cases are attacks (4) to (6): (4) should be detectable – especially once we have gyroscope and accelerometer sensors – by aligning multiple tracks and determining their similarity. The local sensor movements on these tracks will be extremely similar, but this can only be detected on the level of multiple tracks, and not from a single track. We will address this in future work as such data has just become available.

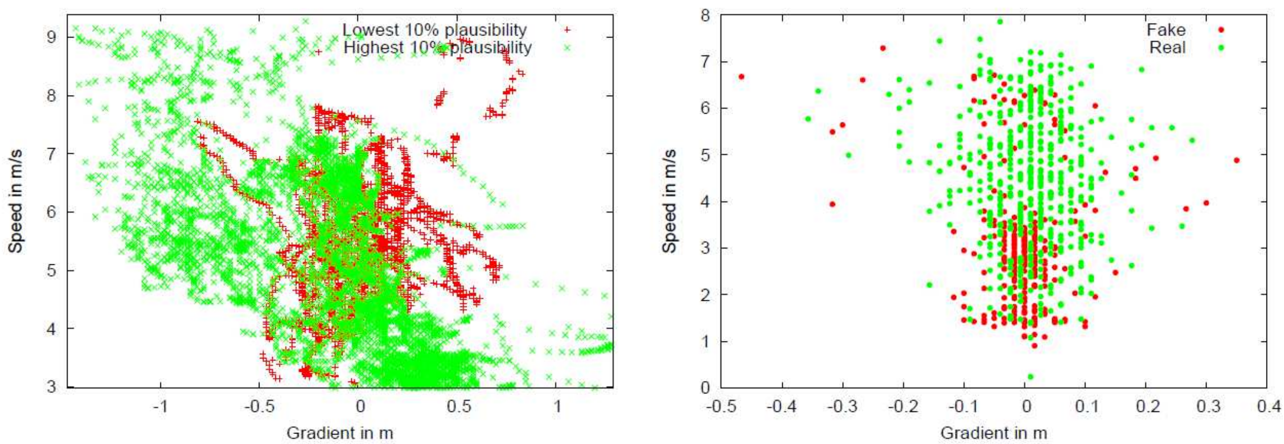

Fig. 4: Left: Scatterplot of gradient vs. speed, coloured by 10% lowest and highest plausibility, on historical data; Right: Same scatterplot on first batch of competition data with by-track user-defined classification Real and Fake.

For attack (5), it is important that not all details of the system are known, otherwise engineering a reverse system is made correspondingly easier. However, since we focus on machine learning techniques throughout, it is likely that creating realistic fake tracks will be very hard, and people will mainly resort to replaying modified existing tracks (6), which should again be detectable by their similarity. Also, only (4) to (6) – and (3) when combined with (4) – ensure potentially unlimited payoff, which is surely the most tempting fraud scenario. It should also be noted that only attacks (3) and (5) can be addressed at single track level with models described here. The other four attacks must be addressed at the level of multiple tracks and will need a completely different approach, although likely one also partially based on artificial intelligence and machine learning techniques. As the most tempting attacks call for many users to be automatically created, another option may be to simply make user registration non-scriptable, e.g. by using captchas or requiring a short cycling sequence with pulse rate (for example, by using the front smartphone camera and pulse-by-face). As this list may be incomplete, we are currently running a competition for cheating with appropriate incentives before deploying the system widely. This should give us sufficient data on other scenarios not considered here. As first result, we obtained two fake tracks which the legacy plausibility system classifies with maximum plausibility.

Fig. 4 shows the results. It seems that for the competition tracks, the distribution of gradient vs. speed is much more similar than for historical data which indicates that new unique attack modes may possibly be found in the newer data.

5 DISCUSSION

New technologies (e.g. navigation and routing apps) in combination with incentive systems (e.g. gamification) are becoming increasingly popular within the cycling community. However, there are still many open questions – for example, how to leave the level of abstract and often gamified rewards and deliver real rewards; and what their underlying value could be. This is mainly related to the problem of quantifying the costs and benefits of cycling in monetary terms and ensuring the quality of tracking data. Privacy concerns also play a significant role here, as sprawling, unrestricted tracking & exploitation methods generate sceptical criticism.

Cycle4Value therefore explores the use of blockchain technologies based on digital tokens to translate track data into value units. In this way, the entire process of distribution, storage and redemption of Cycle Tokens can be mapped and automated. Thanks to blockchain technology, all accounts can also be secured against fraud and hacks. Since each “cycled” token appears once and uniquely as a public entry on the blockchain, it also has a unique, ideal value. This leaves behind the purely digital incentive level of common gamification approaches and gives cycling a real value.

Another innovation in the project is the use of machine learning for plausibility checks of registered cycling trips or cycling routes (“tracks”). In contrast to ad-hoc code, which typically uses highly predictive features (e.g. maximum acceleration and speed) and is thus relatively easy to circumvent by suitable countermeasures (e.g. driving slowly, controlled acceleration), in machine learning the learned model will typically use a large number of slightly predictive features, making it significantly more difficult to intentionally cheat the system. Another advantage of a machine learning system is that it can be retrained if new attack types are found and thus can remain useful much longer. However, as we mentioned a single-track prediction is not sufficient. It is also necessary to compare multiple movement patterns using appropriate distance metrics to prevent “multiplication” of “genuine” bike rides (e.g. using multiple smartphones in the backpack or on the bike). Cheating by using alternative means of transport with similar movement patterns is thus effectively prevented as far as possible. Care is taken here to ensure that “real” journeys continue to be recorded correctly (as small a false positive rate as possible). Towards this goal, we are currently running a competition for cheating with appropriate incentives and are researching fast algorithms for multiple track alignment. The solution presented in this paper is currently being implemented and piloted using the Bike Citizens Beta App. First reviews received by stakeholders suggest this approach has potential to shift mobility behaviour in the right direction.

6 ACKNOWLEDGEMENTS

This project is funded by the Austrian Research Promotion Agency (FFG) and by the Austrian Federal Ministry for Climate action, Environment, Energy, Mobility, Innovation and Technology (BMK) as project Cycle4Value (873384).

Densification of the Existing Urban Pattern: the Case Salzburg

Stefan Netsch

(Prof. (FH) Dr.-Ing. M.Eng. Stefan Netsch, Salzburg University of Applied Sciences, 5412 Puch, stefan.netsch@fh-salzburg.ac.at)

1 ABSTRACT

Most European cities are facing the challenge of a continuous demand to enlarge their housing stock. Based on the common sustainable development goals, this demand should be created in the range of the existing urban pattern, which means that transformation of areas or the increase of density on underused plots. A town like Salzburg, which is characterized by a high amount of valuable historic buildings and neighborhoods, has also to deal with this question. The strategy of the past years was not to extend the urban pattern in the green surrounding, because of the proximity to the mountains and protected landscape. This paper will give an overview of the chosen strategy and development of the past 25 years by studying 22 different projects. The reason for these projects was, that there are arguments that the densification of recent projects in Salzburg is too high and delivers unsatisfied urban projects. This study is based on an overview of the development of different densities and approach of the projects. The conclusion will discuss the different opinions and will give recommendations about an improved approach to a sustainable future planning.

Keywords: urban pattern, Salzburg, densification, strategies, case study

2 INTRODUCTION

2.1 Densification as a method to reduce land use

In the latest Land-Report of the WWF in 2021 Austria is approved for falling the national sustainability and climate goals. One reason for this development can be followed up by the land consumption, which amounts recently to 13 hectares per day (WWF 2021). The target is 2,5 ha per day, which seems uncertain when and how this can be reached. (Bundeskanzleramt 2020) More than half of the land consumption can be attributed to the building development, which leads in the planning projects and policies to an intensification of densification strategies. These recommend avoiding further greenfield developments, instead they promote the densification of the existing urban structures. Which means that the future development should be focussed within the limits of the city by using different approaches, which are in general similar and have all in common to increase the density (Nagel 2018). There are different methods ranging from adaptation and extending existing building structures to a total reconsideration of the land usage. By increasing the density also another benefit is that more people are living in the city which helps to maintain and sustain other functions, like shopping or retail, which is in general moving to the outskirts of the centers. (Nagel 2018) One consequence of intensive land use is the need to build new roads, which are economically problematic, especially due to the effect of urban sprawl. (Fitz, A. et al. 2020)

Figure 1: Development of shopping and retail services at the outskirts of the cities (Source: Stefan Netsch)

There are two different definitions used in the same way: densification and inner-city development. The aim which both imply is similar, but the difference is that densification is an instrument, which tries to create a higher density by using existing building structures, while the inner-city development on the usage of not or underused plots is directed. (Spitzer et al. 2017) Using the existing building structure is mostly done by extending the roof structures or adding a new floor. Both methods are depending on the existing building structure, while the method where the building is demolished is based on the development of a new building. (Wong 2017)

Figure 2: Extending the housing units by roof-stacking (Source: Stefan Netsch)

The usage of vacant or not properly used plots, like stacking grounds or former commercial areas or football grounds are seen as very suitable spaces to develop in an already developed situation as potential densification cases. Another case of densification can especially be seen in single family house estates, where usually the plot is quite large, and the building is very small in comparison. This is also a potential whereby adding a building the density will be extended.

Figure 3: Densification of a plot by adding a second single family house (Source: Stefan Netsch)

To measure density there are different methods, which are often based on the density created by the building on the plot. This is expressed in the form of the ground space index (GSI) and floor space index (FSI). (Roskamm 2016) Other possibilities the measurement by dwellings per hectare or by the population density per hectare. In opposite to the rational facts of the building, these both measurements give more an impression about the human acitity and the usage. (Sim 2019) In general density is related with the factor of developing more floor space, which indicates a greater value for the real estate development (Berghauser, Pont 2009). Next to the discuss of density the discussion of inenr city development is very much linked to the mix of uses. During the post war times most cities in Europe followed the concept of the functional separation, while in recent developments the concepts where influenced by the idea of the compact city (Richter et al. 2018). One of the major topics of the compact city is the implementation of mixed uses within the building or the neighboorhood. The purpose of this approach is to fullfill the basic needs, like smaller shops or social services like kindergardens or doctors, of the inhabitants of the neighboorhood. The challenge of the densificatication of the inner city is besides the physical implementation of new buildings and urban structures, also the challenge to provide sufficient infrastructure, such as social facilities or public services. These infrastructures are in demand by residents, especially at the neighbourhood level.(Böhm et al. 2016) The danger is that the densification will lead to an undersupply of this type of infrastructure as the population increases. This contribution will give an overview how this practice is implemented in the urban pattern of the city of Salzburg and indicates some of the advantages and disadvantages, which go hand in hand with the densification.

2.2 Situation of Salzburg

The city of Salzburg is also the capital of the Federal Province of Salzburg (Austria) with about 157.160 inhabitants (Stadt Salzburg 2020). It has with of 2395 inhabitants per km2 about 50% of the density of Vienna, which has 1,9 million inhabitants (It is not a fast growing city and has a moderate growth with around 5-10% (Stadt Salzburg 2020).

Figure 4: Historical inner city of Salzburg (Source: Stefan Netsch)

Between 500 and 1000 new flats were developed annually during the study period from 1994 to 2020. In total 6400 new flats were newly developed. (Stadt Salzburg 2020) Even if Salzburg is not really growing rapidly and the scenic location suggests great land potential, demand for land is great and availability is very limited. The overview of the examined examples show that the focus of the project development is directed to densifying the city and to reuse former used plots for the inner city development. Greenfield development on former not sealed or intended for other uses occurs very rarely and if then on a small scale. Another necessity for inner development in Salzburg is the high protection status by UNESCO. Including the buffer zone, the city has almost 500 ha protected urban structure, which can be developed further, but the conditions are very specific in order to preserve the baroque character of the city. (UNESCO 2017) Most of the first restrictions relate to the design of the façade or the height development of buildings, as various visual axes are to be preserved in the urban area. If projects are implemented in this inner-city area, they will be reviewed by a design advisory board and, if necessary, adapted according to the specifications. (UNESCO 2017)

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

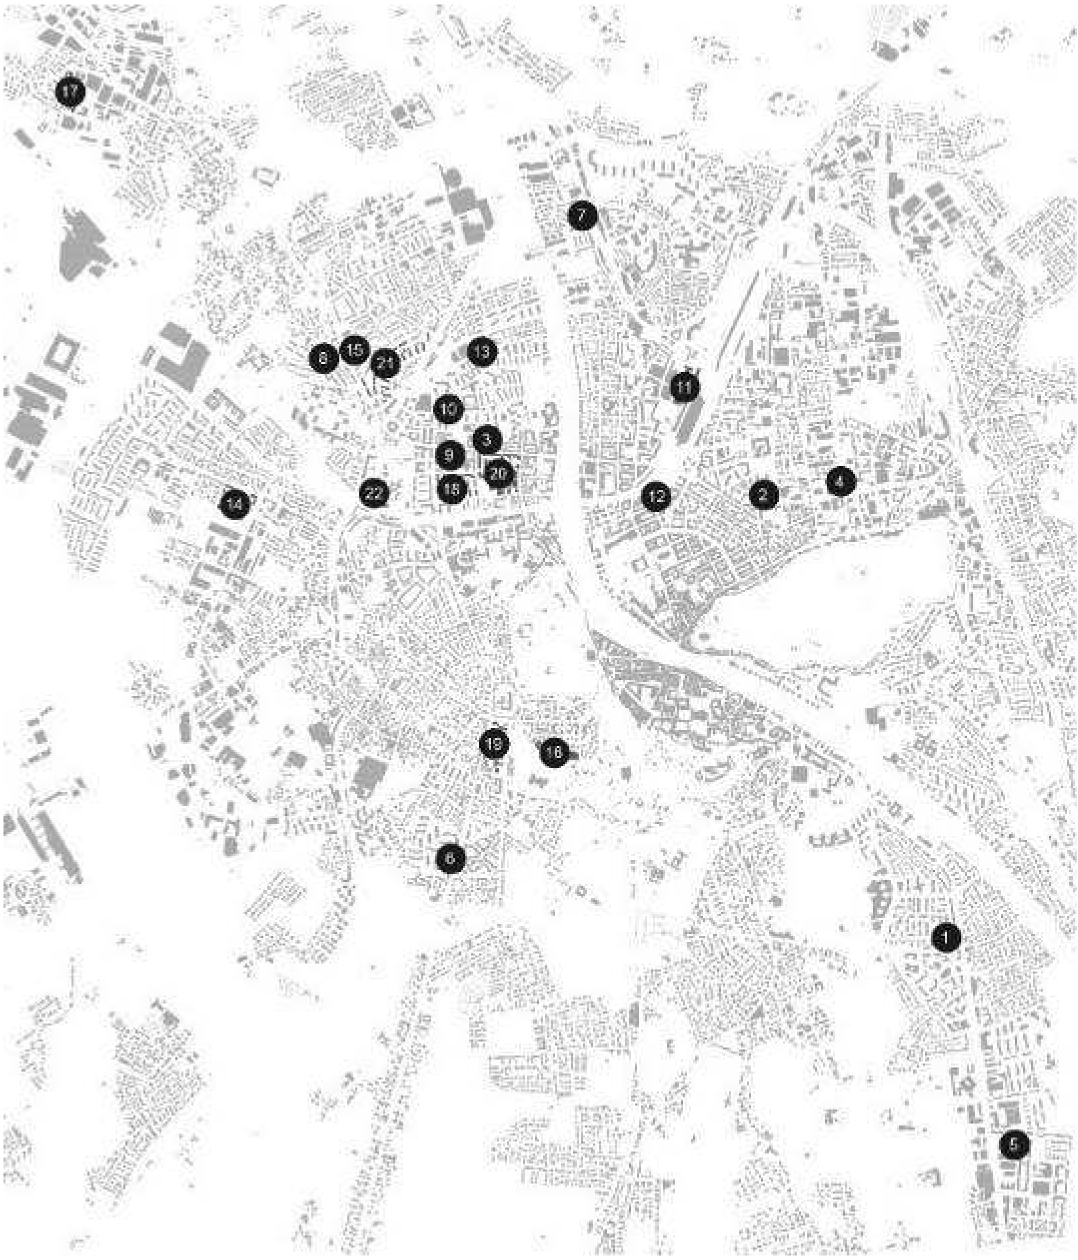

Figure 5: The distribution of the densification cases are concentrated in the northern part of the city of Salzburg. In this area of the city, dense housing is concentrated, whereas in the south there is a transition to the open landscape by means of detached houses. (open access map data retrieved from SaGis; editing by the author)

2.3 Methods

This research in Salzburg was done in 2020 by a descriptive case study approach that pursues a structured comparison of different densification projects. Within the research, 22 examples have been studied, which illustrate the variety and possibilities of densification projects in the past 26 years. The year 1994 was chosen because then one of the first significant projects "Hernau" was realized. The project was carried out in three stages. Within the first stage a desk research was done to map the project and to analyze the basic data (e.g. size, housing units, additional functions, e.g.). The stage of the field work was necessary to conduct an onsite mapping to collect further aspects and data, which was necessary to compare and frame the projects in a bigger picture of the city. In the last step, data which was provided by the City of Salzburg was used to add further data that contribute to the complete presentation of the projects. In some cases, the provided data was checked with local architects, housing companies or the planning departmenet of the city.

3 DIFFERENT CASES OF DENSIFICATION

In total there were 22 cases collected, with the first project finalized in 1994 and the last one in 2020. During this time period there was a continuous development of densification projects, but the realization period is depending on the complexity of the project.

The range of size of the individual projects is wide. It ranges from small interventions with 0.11 ha to new urban blocks with 7.5 ha. The distribution of the individual projects shows that they are mostly smaller projects with less than two hectares total area. In total, more than 46 ha of already developed urban land could be used again. The number of newly created residential units also depends on the respective area size of the projects. In the smallest case this is 12 flats and in the largest case more than 600. This is due to whether only a single building was realized or a new neighborhood. An exception is project no. 4, which was implemented as an office and commercial project. This is remarkable, as these types of projects tend to be located on the outskirts of the city.

Table 1: Overview cases

In summary, conclusions can be drawn from the individual projects for the four following thematic areas, which on the one hand show approaches to solutions, but also point to the issue of inner development, which must be analyzed and solved individually in each project:

3.1 Typology of project

Looking at the size of the potentials to be developed shows the challenge that cities like Salzburg have to face. The size of the respective inner development projects is getting smaller and increasingly concentrated on the level of a single plot of land. Larger brownfield developments are becoming increasingly difficult, as much of this space has already been activated in the past. This challenge “finding new spaces” for inner city development a lot of cities are facing. At present, the availability of land is also becoming increasingly difficult due to rising property prices.

If it is not a single plot, which can be used as a kind of infill development, the tendency is to great projects, which do not only serve the inhabitants of the neighborhood, but also on a wider scale. In larger projects such as Maxglan (No. 14), it becomes clear that the offer in addition to housing like kindergarten or the generous open space is not only intended for the residents of the project, but also for those who live in the urban neighborhood.

Figure 6: Development of social infrastructure tp provide services for the neighboorhood (Example 14)

Figure 7: Addition of the existing urban structure (Example 12).

The possibilities offered by inner development go far beyond the mere production of living space. They offer the chance to solve the deficits that exist at the level of the urban district. In most cases, it is a question of creating infrastructures that serve the public, such as public spaces or social infrastructures (e.g. kindergartens, playgrounds, etc.).

Density

The density values of the projects show a broad range of different GSIs and FSIs. However, the statement of the values is limited to purely factual statements and less about the perception of the current density in the context of the project. It is difficult to make a statement about the quality of the project purely on the basis of density values. Rather, the actual project must be perceived in the context of its surroundings. This becomes clear in the case of project no. 11, for example, which on the one hand has a high density due to its central urban location, but on the other hand is also due to the urban planning situation. Because of its size, this project contributes to the continuation of the urban structure. The totality of the case studies shows the great diversity of the density values achieved, even if the project areas are comparable

The real differentiation takes place through the production of the number of housing units. However, a high number of dwellings does not necessarily mean a high density of use by residents. Much more remarkable as a result is that most projects achieve a density of 80 to 120 dwellings per hectare. It can be concluded from this that the normative information from development plans does not necessarily contribute to the perception of density, but that other parameters are also important.

3.2 Open Space

The challenge of free spaces in the projects is manifold. They have the fundamental task of providing internal access, but on the other hand they are also an indicator of the quality of stay. In addition to seating and bicycle stands, many projects also have the option of play areas.The differences in the type and design of the public spaces vary in the sample collection greatly in the projects and depend on the type of spatial context. The spectrum ranges from large park-like areas (No.14), to small-scale green and play areas, to urban outdoor spaces like No.20.

Figure 8: Public Spaces in the Riedenburg (Example 19)

The diversity in terms of project size and type also has an impact on the type of publicly accessible space available. In the development of a single plot of land, residential open spaces are particularly developed at ground level, leaving little space for the public. However, in projects where an almost park-like green space has been developed, it can be assumed that this is also useful for the neighborhood.

3.3 Mixed Use

One of the key factors of the compact city is the variation and combination of different usages. Particularly in the first-floor zone, it is evident that in the urban area a use that attracts the public often contributes to the

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

revitalization of the neighborhoods. In addition to retail, this can also be everyday services, such as laundries, post offices, etc. In many cases, the floors above are occupied not only by residential units but also by other facilities such as offices (e.g. architects, lawyers, etc.) or doctors' surgeries. This direct combination of uses with housing means that many routes can be eliminated.

Within the implemented projects, different uses are brought together. It is obvious that the majority of the projects were implemented with usage on housing (n=15). Only a small number, such as project no. 1, show a mixed use with residential and mostly commercial use. Project No. 4 is an exception with purely commercial use, which was implemented in the urban area.

Figure 9: Different uses of the basement zones (Example 20)

The example of the Stadtwerkareal shows the positive mix of uses. Since this part of town has a very high population density, uses in the first floors that contribute to the support of the residents are particularly important in addition to the public spaces. Therefore, many community facilities are located there, ranging from the district office to homework supervision to rooms that can be rented temporarily It is undisputed that one of the central problems of mixed use is that the spaces in the first floor zone are usually difficult to market and are only suitable for living to a limited extent. For this reason, many projects also forgo mixed use, which is also challenging in terms of floor plan development.

4 CONCLUSION

The densification ofneighboorhoods in the incner city pattern has a lot od adavantages, like the reduction of land comsumption, the addition of new housing units or the extension of usages, which are needed on a wider scale. But espacially the existing infrastructure needs a special attention, because it is succesfull to use the technical infrastructure like roads, sewage installation, etc. or the social infrastructure like kindergartens, schools, playgrounds, etc. more efficiently. But it needs a careful planning because there is the threat that by an too intensive densification of an overloading of the the existing structures. It is therefore necessary to look at inner development on a larger scale.

Density in particular is viewed critically in many projects and also leads to their rejection. However, in many cases it is not the density itself that is the problem, but rather the increased burden it places on public space or streets. This leads to a negative perception, which could, however, be taken into account in planning.

The problem, however, often lies in the fact that it is a matter of individual projects that only appear to be problematic in their entirety because they are embedded in the neighbourhood.

1 ABSTRACT

Each year people on the planet produce tons of waste. The more urbanised a country is, the more residues it produces. Its management is one of the most expensive services to municipalities and in many countries, it is still one of the main concerns. Many environmental and health problems are associated with poor waste management practices and the absence of circular economy approaches. Moreover, traditional waste management systems are designed from a waste production perspective. The process is focused on the collection of the produced waste, system coverage of it across the urban territory and its expansion. The prevalent way of thinking is still: out of sight, out of thought. Fewer efforts are put into transforming solid waste management in the direction of having a material or resource flow. Often municipalities work in silos and for this reason, solid waste is regarded as an independent process, acting on its own, designed and operated individually. Although there are many overlaps that the operation can have if it is planned in an integrated manner.

The paper presents solid waste management (SWM) regarding this integrated perspective, highlighting the synergies that could be achieved with other sectors such as mobility and logistics. It describes what can be understood under material circularity from an SWM perspective and how the principles and ideas described in the paper can be integrated into the urban planning of future cities ensuring that the waste is handled as a valuable resource.

Keywords: Solid waste management, Circular economy, Zero waste, Reuse model

2 NEED FOR CHANGING THE TRADITIONAL WAY TO DO IT

2.1 Urban Waste Crisis

Rapid urbanisation and exponential population growth are undeniably significant phenomenon since the past century. The world population is expected to increase from 7.9 billion in 2021 to 9.9 billion by 2050 (IISD's SDG Knowledge Hub, 2020) and more than two-thirds of the world population is predicted to live in cities. The World Bank (2020) indicates that nearly 7 out of 10 people will live in cities. Similarly, another alarming trend that is in direct proportion to urbanisation is global waste production. Currently, total solid waste annually generated in the world is estimated to be around 7 to 10 billion tonnes and as of 2016, 2.01 billion tonnes of municipal solid waste is generated (Kaza et al., 2018). Here, according to Kaza et al (2018), municipal solid waste refers to waste generated by residences, commercial enterprises and institutions. Other wastes such as industrial, medical, electronic, and construction and demolition waste are not considered to be municipal solid waste.

Kaza et al's (2018) What a Waste 2.0: A Global Snapshot of Solid Waste Management to 2050 report indicates that global waste is estimated to increase by 70% by 2050 and it is also expected to surpass the population growth. According to this World Bank report, the global average of waste generation was 0.74 kilograms per person per day in 2016 and the United States has the highest average of waste generated with a per capita of 2.21 kilograms a day. Furthermore, COVID-19 has caused serious disruptions in the way waste is generated and healthcare waste is said to have monumentally increased due to the pandemic (Das et al., 2021). The pandemic has further instigated an unprecedented increase in the consumption of single-use products mainly plastics and experts call for a zero-waste approach and stress on the need to shift from a linear to a circular economy (Sarkodie and Owusu, 2020).

These alarming trends in waste generation in urban areas is a universal issue. Urbanisation coupled with population growth in cities is the driving force behind the increase in the amount of waste generated. Moreover, solid waste challenges concern people, municipalities, and cities alike, affecting them and the environment in multiple ways. SWM is especially a major challenge for municipalities of fast-growing cities and is also undoubtedly one of the most expensive services offered. The way waste is collected, treated and disposed of in cities requires utmost attention and the problems related to this pose a great challenge to cities

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

and municipalities worldwide. Poor and improper solid waste management not only can cause various health, environmental, and social challenges but also influences pollution levels in cities. Greenhouse gas such as carbon dioxide and its equivalent generated from the way solid waste is treated and disposed of, are expected to rise from 1.6 billion tonnes in 2016 to 2.6 billion tonnes by 2050 annually (Kaza et al., 2018).

Waste management practices, quantities and quality of solid waste generated vary significantly due to demographics and socio-economic variables (Boateng et al., 2016) and in rural and urban areas, developed and developing countries. More developed and industrialised countries tend to have a better waste management system in place but at the same time, high-income countries produce more waste per capita and consume more goods. According to the World Bank estimate, in 2016, developed nations such as the United States, Canada, Australia and Germany's annual waste generation per capita per day is greater than 1.5 kilograms. Whereas, in several developing countries of Africa, Asia, and South America this number ranges from 0 to 0.99 kilograms.

In 2016, countries of East Asia (mainly China) and the Pacific region collectively generated the highest amount of waste globally. However, according to the 2018 World Bank report, there will be a shift in this trend. Waste generation in especially low-income countries is projected to be incremental. The fast-growing nations of Sub-Saharan Africa, South Asia, and the Middle East and North Africa are estimated to at least double the amount of waste generated by 2050 (Kaza et al., 2018). Furthermore, urban waste generation and its composition are closely linked with changing incomes of rapidly urbanising and industrialising cities. The composition of municipal solid waste ranges from organic and metal to paper and plastic waste. This composition differs among low-income and high-income countries. While most of the waste generated in low-income countries is organic waste, packaging waste forms the bulk of waste generated in high-income countries since people in cities rely on packaged and industrialised products. Overall, these statistics indicate that the urban waste crisis is a universal challenge.

Further, it is essential to take political issues into account, as urban waste is mainly exported to other local authorities with which agreements need to be reached. On a macro level, developed countries generally export waste to developing countries. To tackle the movement of hazardous waste among nations, nearly 180 countries worldwide and the European Union joined the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal that entered into force in the year 1992. On a micro level, urban waste may be collected from one authority that oversees the waste collection and exported to other local authorities that provides services for processing. The World Bank report indicates that there are different administrative and operational models across municipalities. An issue arises when the municipalities have different viewpoints and priorities in managing waste. To address this issue of differences among municipalities and other agencies, a common platform is required to efficiently coordinate decisions and regulate the management.

2.2 Traditional Waste Management Systems

In most countries, the principal aim of local administrations is to get rid of waste to not disturb the cities' landscapes. If its management works "well" it is not given much attention or resources. Hence, systems are traditionally designed from a waste production perspective. Efforts are put especially on the collection to keep the waste out of sight and consequently out of mind. This applies particularly to developing but also emerging countries, which grow at a very fast rate making it hard for them to keep the pace in the expansion of the system on par with the waste increase. Often the waste is informally deposited on the street and arbitrary dumpsites appear in cities. When cities have a problem in managing their waste, it becomes immediately visible and gets worse day by day. Uncontrolled waste management can easily become dangerous as it gets mixed with hazardous or/and medical waste not only for people involved in collecting disposing of waste such as waste pickers but also for the environment as it causes air pollution and soil contamination. In this sense, what tends to become a priority is to get it out of the way by collecting it, but sustainability is usually not considered.

The administration is usually one of the reasons for the deficiencies in waste management systems as it is not handled as such a relevant matter. In many cases, the planning and operation take place in an isolated form and not necessarily in coordination with other sectors such as energy, agriculture or mobility. In addition to this, the systems vary among high-income and low-income countries. Waste management in cities is generally supervised by local entities such as municipalities. Globally, 216 cities reported a dedicated solid waste management department, whereas 21 cities do not have a dedicated department and this information is unknown in 131 cities (Kaza et al., 2018). Since solid waste management requires an inter and transdisciplinary approach, most often cities struggle to coordinate comprehensively to address any issues that might occur. The World Bank studies indicate that municipalities mainly take a decentralised approach in managing their waste. Furthermore, a recent trend in cities suggests that municipalities are increasingly collaborating with the private sector and public-private partnerships to efficiently manage their waste. For example, many municipalities in Indian cities have employed private contractors for the transportation of municipal waste (Sharholy et al., 2008). In addition, inter-municipal cooperation, as a partnership between two or more municipalities established for waste management is a notable example that has gained acceptance in Europe. This cooperation between municipalities is beneficial because it may increase efficiency, reduce costs, and aid in reaching economies of scale. Coordination is the key to successful partnerships. Few European countries such as France, Spain, Italy, and the Netherlands have inter-municipal cooperation to manage waste (Kolsut, 2016) that has resulted in productive waste management systems.

Forms of the so-called Smart Waste Management can be found today in many developed cities. The term is applied to a type of management that uses technology to increase efficiency. This is allowed through intelligent routes for the trash collectors, the avoidance of both unnecessary trips and congested streets but also the use of mobile applications to better inform the citizens about the service provided. The implementation of this type of management uses different types of devices such as Global Positioning System sensors and ultrasonic level sensors, machine-to-machine connectivity and have the potential to reduce time in the collection processes and the costs.

Recycling systems are widely applied worldwide but the global recycling rate reflects how poorly the systems are implemented in general. The recycling rate is used as an indicator to measure progress in many countries. Firstly, the recycling rate is measured as the percentage of waste recycled from total generated waste. However, Hotta et al (2015) highlight that this indicator is defined and calculated differently among different nations especially in Asian countries due to the existence of the informal recycling sector. Due to these varying methods to measure recycling rates, it is harder to draw parallels. In 2019, the EU generated 502 kg of municipal waste per capita and recycled only 48% of its waste (Municipal waste statistics - Statistics Explained, 2021). In addition, compared to its European counterparts, Germany performs the best in the world, topping the list with the highest municipal waste recycling rate of 66.7% (Eurostat data 2019). Whereas, according to the OECD report (2015), among the 34 OECD nations, Chile and Turkey are the worst performing countries when it comes to municipal waste management with a recycling rate of merely 1%. Another significant result stated in the report is that New Zealand comes at the bottom of the list that disposes of all its municipal waste in landfills. This suggests that be it a high-income or low-income country, recycling rates are not uniform across continents. A different approach and smart innovative solutions are required, and much work needs to be done to address challenges that affect recycling rates.

2.3 Next level Circularity

Circularity or also notably known as the circular economy is an emerging concept that refers to a sustainable model of production and consumption of products and services across multiple industries. Based on several definitions of circular economy, Geissdoerfer et al (2017, p.759) comprehensively define the circular economy as a “regenerative system in which resource input and waste, emission, and energy leakage are minimised by slowing, closing, and narrowing material and energy loops.”

Globally, the current and conventional model in consumption of goods follows a linear model of ‘take-make-dispose’ (MacArthur 2013). This linear approach causes depletion of non-renewable resources and is a threat to the environment. In contrast to this, the circularity model consists of a closed-loop approach. That is to say, the model is sustainability-driven which reduces the consumption of resources and generates less waste. In this case, waste is considered a valuable resource rather than an issue. It can be said that this is the best method to manage waste. Furthermore, the circularity model could result in the reduction of carbon emissions, greenhouse gas emissions and waste streams. The MacArthur Foundation’s report ‘Towards the Circular Economy’ (2013) presents that implementation of the circularity model could lower materials consumption by 53% by 2050. Considering the trends in waste production and management systems, it is evident that a well-informed integrated change is urgent and crucial.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

The process of using resources to make materials and materials to make products requires high amounts of energy. Worrell et al. (2016) highlight that nearly 25% of global CO2 emissions is produced due to materials production. Consequently, waste generation and greenhouse gas emissions are inevitable by-products of material production. Although on a global scale, greenhouse gas emissions from waste management are less than 5%, it is still crucial for a system change since materials consumption and production patterns are influenced by the growth of cities. Cities in the future with serious intentions of reducing their negative impact on the environment and consciously using resources and pursuing sustainable operation and ways of doing should aim for what we call here a “Next Level Circularity”. The concept of next level circularity demonstrates the change in a systems perspective. It highlights that to avoid and minimize waste production to the furthest extent, the systems should be looked at through the lens of materials perspective. Recyclable material systems should be designed to achieve material circularity. Nevertheless, to practice this type of circularity, cities must implement measures and specific frameworks such as Ecological public procurement policies, Local production, repair, reuse and recycle initiatives, Eco-design principles in the built environment, Bio-intensive urban agriculture, Energy generation from biomass, Innovation in water and waste management systems, Infrastructure solutions for e-mobility and low-energy districts.

2.3.1 Material Pact

Packaging materials are an important contributor to municipal solid waste. Concerns about packaging waste, particularly plastic packaging, and its negative and long-term environmental effects are growing. Despite increased concern over plastic pollution, plastic manufacturing and consumption are expected to continue to increase in the next decades (MacArthur 2013). Numerous variables, including governmental and legal changes, there is a growing concern about food and packaging waste, environmental pollution, and global demand for food and energy resources. All these influences the development of sustainable packaging that is made from renewable and environmentally friendly materials, as well as sustainable waste management options at the end of product life.

The Material Pact can be defined as a network of initiatives that brings together all relevant parties on a national or regional level to create solutions for a circular economy for packaging materials. Each initiative is directed by a local organisation and brings together governments, corporations, and residents around a shared vision and a set of ambitious local goals. Redesign and innovation may help to eliminate redundant and problematic plastic packaging. Before plastic was invented many products such as vegetables, soaps and other items were sold without any packaging and this was a norm in selling products. Today packaging is predominant and overused not only for practical reasons but also used for special design purposes and other unnecessary motivations. A shift in behavioural change can be achieved by awareness-raising campaigns and encouraging more conscious consumers.

For instance, packaging and the use of plastic, in general, should be regulated by the local administration. In this sense, the usage of plastics can be clearly defined, and only certain plastics must be allowed in the fabrication of packaging. The material pact regulations and guidelines are designed aiming that every plastic packaging is reusable, recyclable, or compostable and only used when and if needed; reuse is promoted instead of single use. According to its characteristics, especially its recyclability, the following materials can be recommended:

NYLON 6 - A potential inspiration source as a material with infinite closed loops Nylon 6, the most popular nylon grade, is a polymer built up by synthesising caprolactam, its monomer building block. Polyethylene Terephthalate (PET) - is one of the most important commercially consumed polymers; it is an increasingly conventional material like paper, wood, metal and glass in a variety of applications.

Polylactic Acid - Polylactic Acid commonly known as PLA, is a polymer made from renewable resources. Contrary to other thermoplastics which are petroleum-based, some of the raw materials used for PLA’s production include corn starch, tapioca roots, sugarcane. Its properties, however, are comparable to other plastics in the industry. These characteristics and consumers’ desire to use a less impactful material have triggered its rapid entrance into the plastic market as a competitive commodity.

Compostable Packaging - Fully compostable packaging should be prioritised. Companies can be incentivised to its design and its local production. Examples of materials for this are mycelium (roots of mushrooms) that can be then composted at home or in the local facilities.

Edible Packaging - Edible food packaging is a sustainable type of packaging that is designed to be eaten or can biodegrade efficiently like the food it contains. Edible packaging comes in many forms and is constantly being improved and innovated to be made from many different types of substances. Already different types of edible packaging are available for different types of food e.g., edible coffee cups in the market.

2.3.2 The Reuse Model

Innovative reuse models, enabled by digital technology and altering consumer preferences, can unleash significant benefits. Reuse is defined in the British Standard and International Organisation for Standardisation, as well as in EU regulations, as shown in Table 1.

Table 1. Definitions of reuse and reusable packaging in standards and directives.

Standards and Directives	Definitions
BS EN 13429: 2004 Packaging reuse [11]	**Reuse**: operation by which packaging, which has been conceived and designed to accomplish within its life cycle a minimum number of trips or rotations, is refilled or used for the same purpose for which it was conceived, with or without the support of auxiliary products present on the market enabling the packaging to be refilled: such reused packaging will become packaging waste when no longer subject to reuse **Reusable packaging**: packaging or packaging component that has been conceived and designed to accomplish within its life cycle a minimum number of trips or rotations in a system for reuse
Directive 2008/98/EC of the European Parliament and of the Council of 19 November 2008 on waste and repealing certain directives [12]	**Reuse**: any operation by which products or components that are not waste are used again for the same purpose for which they were conceived
Directive 2009/125/EC of the European Parliament and of the Council of 21 October 2009 Establishing a framework for the setting of ecodesign requirements for energy-related products [13]	**Reuse**: any operation by which a product or its components, having reached the end of their first use, are used for the same purpose for which they were conceived, including the continued use of a product that is returned to a collection point, distributor, recycler, or manufacturer, as well as the reuse of a product following refurbishment
ISO 18603: 2013 Packaging and the environment—Reuse [16]	**Reuse**: operation by which packaging is refilled or used for the same purpose for which it was conceived, with or without the support of auxiliary products present on the market enabling the packaging to be refilled **Reusable packaging**: packaging or packaging component that has been designed to accomplish or proves its ability to accomplish a minimum number of trips or rotations in a system for reuse
BS 8001: 2017 Framework for implementing the principles of the CE in organisations [23]	**Reuse**: operation by which a product, component, or material can be used again without requiring any reprocessing or treatment

Table 1: Definitions of reuse and reusable packaging in standards and directives (Muranko et al., 2021).

These definitions emphasize a systemic and performance-driven approach to reuse, as they refer to the presence of a reuse system, auxiliary products that facilitate reuse, a minimum number of reuse rotations or trips, and the fact that reusable packaging eventually becomes waste and must be recycled. Reuse is not new to the consumer and was certainly there before as common practice before plastic in packaging was invented, but it is an emerging practice. For example, Bronze Age archaeological discoveries have shown repair activity on broken or abandoned pottery in Greece and the reconditioning of bronze and iron razors for reuse across Europe. Records of public actions in late 18th-century European countries, e.g., the Netherlands, show that various second-hand household products, such as kitchen utensils, were commonly bought for reuse (Muranko et al., 2021). With the increased interest in reuse, reuse model frameworks have gradually appeared in the literature. Just like the circular economy approach, reuse can mitigate negative environmental consequences induced by the intense mining, manufacturing, distribution, use, and disposal of packaging, including waste accumulation and contamination of the air, water, and land (Pardini et al., 2020).

Shifting consumer preferences have in some countries enabled a new paradigm of creative reuse that can yield major benefits, such as digital technology and changes in user preferences. Such models can aid in delivering a superior user experience, tailor products to each user's unique demands, gain insights about users, solidify a brand's identity, streamline operations, and save money.

Also reusing materials created by a refurbishing process is an operations technique that involves slowing the flow of materials by extending the product utility. In the waste pyramid, reuse is followed by recycling, which has become a very popular and very common practice. Reuse however should be prioritised and preferred as it allows for lower ecological and carbon footprint. The reuse system has three main elements, namely the re-user behaviour, reusable product and finally the reuse-enabling infrastructure.

The models can be sequential and/or exclusive reuse models (Muranko et al., 2021). Exclusive reuse involves a product that is repeatedly used by a single user throughout the product's lifetime for the same purpose for which it was intended, as well as using and enhancing reuse-enabling infrastructure (Muranko et al., 2021). In this model, the user owns the reusable items, retains ownership of the product, and is accountable for recovery, continued use, and recycling after the product has been retrieved for re-introduction into the consumption phase. For an item to be considered as recovered, its functionality must be re-established, and a person or organisation must be prepared to use it. The item can then be reintroduced into the cycle of ‘utilisation-recovery-preparation’. An example is durable cloth sanitary towels (e.g., Bloom and Nora), which are composed of a consumable (an absorption layer) and a facilitator (structural layer), both of which are reusable. The consumables of products belonging to this model are typically made of non-perishable materials (e.g., fabrics) that are durable enough to withstand multiple uses. Various examples of the reuse model can be seen in Fig. 1.

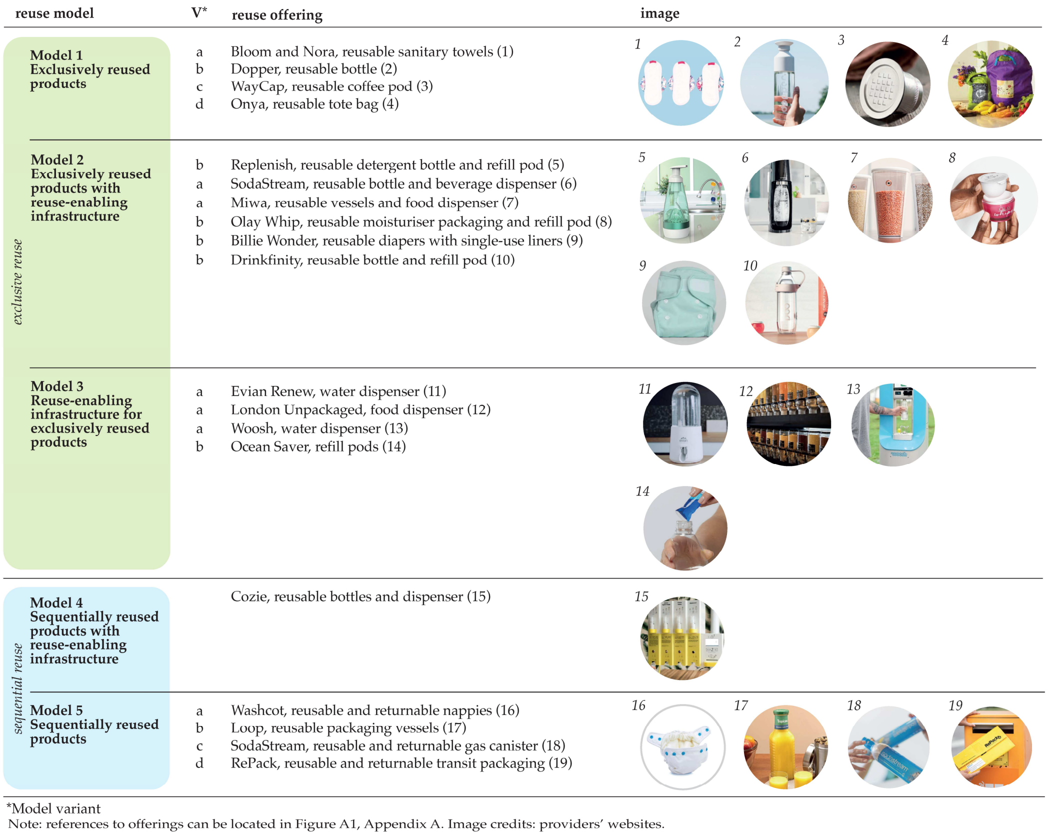

Fig. 1: Various examples of the Reuse model (Muranko et al., 2021).

Sequential reuse is a product use behaviour in which a reusable product is used consecutively by multiple users throughout the product lifecycle for the same purpose for which it was created and with the help of reuse-enabling infrastructure (Muranko et al., 2021). When sequential reuse models are implemented, the user has access to a reusable product. The user is responsible for returning the reusable product to the provider, who is then responsible for returning it for reuse and recovery, and on return to the consumer. The ‘Utilisation-Recovery-Preparation’ is a cycle of steps the manufacturer uses until the consumer does not return the product, when the reusable product is no longer fit for use, or when the provider decides to discontinue making the product. Reuse models can provide a database with the information needed to determine if a reuse offering suits the needs of the target audience and their technological, infrastructural, and financial capacities. This model is commonly used in-store dispensers used to refill skincare products into parent reusable, returnable vessels and refill pods such as SodaStream.

2.3.3 Sustainable Packaging

In addition to proper packaging design, sustainable packaging involves the creation and usage of packaging that is more sustainable. To meet the changing consumer demands, manufacturers must also adopt newer life cycle inventory (LCI) and life cycle assessment (LCA) methods, which will assist them to employ packaging that has a lower environmental impact and ecological footprint (Lee et al., 2005). To see all the design, choice of materials, processing, and life cycle, the package needs additional in-depth study and documentation. Sustainable packaging must meet the functional and economic needs of the present without jeopardizing the ability of future generations to satisfy their requirements. Instead, considering sustainability to be an end state, it should be regarded as a continual process of improvement. There are several regulations on both business and consumer levels when it comes to sustainable packaging. Some requirements must be put in place by law while others are up to the discretion of packagers. Investors, employees, management, and customers can have a direct impact on corporate choices and help create environmentally friendly company policies.

The main goals of sustainable packaging are:

(a) Convenient and functional product protections, safety, and regulatory compliance.

(b) Low-cost packaging: The less expensive, the better, because the lesser it is, the more one is willing to use it.

(c) Foster a long-term commitment to both human and environmental health.

In addition to the goals, the factors for designing sustainable packaging that must be taken into consideration are reusability, recycling rate, water and energy usage, use of renewable resources, and atmospheric factors. Sustainable packaging describes a range of approaches that meet multiple sustainability criteria, with little or no impact on the environment and its resources (PWC Plus 2019).

3 MATERIAL CIRCULARITY IN THE CITY OF THE FUTURE

Many infrastructural and management factors are involved in transforming the urban environment into smart communities. Technology or infrastructure is only one component of this transition; the collection of suitable data to define smart solutions, as well as the changes in consumer behaviour driven by smart solutions, are two other pillars of future smart cities (Esmaeilian et al., 2018). To address the problem of waste management, a new approach to waste collecting and treatment is required but most important for its overall planning and the general concept people have about waste needs to change. In future planning, the talk should not be anymore about waste management but rather material circularity systems. The system should from the very beginning consider the whole product life cycle and the vision of the entire process should be clear. This means that once a product is designed, its end and the process behind needs to be clear. Conscious and responsible planning should aim for a waste-free city in which waste is avoided at all times and if any, it is then minimized and converted into resources for other systems. In general, to become a zero-waste smart city, three approaches are required: waste avoidance, effective waste collection, and ultimately, effective value recovery from collected waste.

Fig. 2: Smart Waste Management System ("Solid waste clipart 5 » Clipart Station," n.d.)

3.1 Cross-sectorial planning to ensure synergies and cost-efficiency in the city of the future

This approach is something that cannot be achieved through isolated planning. Synergies within municipality departments but also with producers and the industry, in general, must be established. Material circularity can only be implemented in coordination and alignment with many other urban planning sectors and in many cases also demand regional coordination. From the production perspective, this should be implemented in alignment with the economic department, or authorities responsible for regulating the products available in the market and its local production. Aiming to make sure that the defined policies as the producer responsibility principle are respected and that products are designed in the best possible way by following the circularity approach. For this reason, strong coordination with the commercial and industrial sectors is crucial. From another perspective, aiming more to a full recovery of nutrients, the alignment with the

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

wastewater sector to combine solid waste treatment with sludge treatment is relevant. Further the process of food waste into compost is the most effective when coordinated with local food production and agricultural activities that demand it.

Besides in a city that allows for new planning or some restructuring, the coordination with mobility and logistics offers great potential for adding efficiency in the process and reducing costs. For instance, in new planned cities, the waste collection should be done using the most efficient and less contaminating technologies. Whenever possible underground systems shall be chosen, and the infrastructure used for waste collection should be carefully planned together with the infrastructure needed for the city mobility and logistics. Future cities will ideally be planned to envision and prioritise shared mobility systems as well as mobility as service approaches. Ideas for this type of mobility include the use of Automated Guided Vehicles that run on magnetic surfaces, the same that can be used for multiple purposes. In this scenario, the car as we know it does not have a place nor the streets as we are used to. The infrastructure created is then planned for being used for a variety of services and purposes, so it would be the tunnels built for the transport of the waste to the collection and treatment facilities, which at the same time can be used for package deliveries and others. The selection of the exact system will depend on the location and density of the community; in higher density areas preference will be given to the pneumatic system for waste collection for reduced carbon footprint and better efficiency. In general, the integration of the different systems, urban services and its infrastructure must be the norm and always prioritised. This applies also to the type of vehicles used, the software, and the hardware employed in the implementation. The coordination guarantees efficiency and reduction of costs at all levels. Regarding the treatment, the proximity principle should be applied to facilitate the local reuse as well as unnecessary transport.

The aim in future cities should be to create a holistic, economic industrial and social framework that seeks to have a city that is not only efficient but also and essentially waste-free. For this, apart from creating the appropriate regulations, creativity, and tech-savviness are necessary as they can encourage people to incorporate more environmentally friendly measures. In this sense, technology can be a great help when facilitating people, the correct handle of their residues. Blockchain has proven to be an ideal player in initialising digital tokens. Blockchain solutions can also help to reduce the ecological ruin prompted by waste in general. Well-designed applications also help in delivering relevant information, such as collections hours, the right use of containers, containers locations, among others. Depending on the needs, this can be complemented with advanced solutions such as smart bins that not only do compacting to increase the capacity of the container but also help with the sorting. They can be especially helpful in tourist places, where the local administration does not have the opportunity and enough time to train the “temporary user” of the services. Finally, gamification and different forms of incentives can bring the right push and motivate the users in the right way to make them part of the solution. Incentives offered can be a great motivation for people to dispose of their waste in the right manner. The incentives can be in the form of monetary rewards that can be exchanged for kilometres of public transport or entrance tickets to certain amenities, discounts for local shops, and other services. Also, the possibility to see people’s progress along the time can be motivating and even more if there is a competition component added, for example among different users, blocks of houses, companies or schools. Many options could be chosen for each specific context, but the combination of the right tools is what can make the difference.

4 CONCLUSION

Since waste is mostly looked at as waste nowadays, meaning, waste is looked at as a valueless and useless entity, cities must realise the potential waste has and must tap into this resource just like any other. The amount of waste generation will only continue to rise with rapid urbanisation and population growth. With waste generation on the rise, poor waste management practices can be dangerous to health, environment, and the costs will be higher to repair the damage than prevent. The consequences can have long negative effects as continuing polluting land, air and water. The existent pressure on the availability of resources and the environmental consequences of linear consumption systems are pushing models of the circular economy. The global landscape and crisis warrant urgent, smart, and sustainable actions.

Ideally, the challenges require a shift in the way waste is treated and generated right from its nascent stage. Materials and products must be designed to last longer and in such a way that they can be utilised in the circularity loop, before even having to refurbish them or recycle; products and material lifecycle must be prolonged, and materials seen as nutrients circulating in safe and healthy metabolisms. Cities and municipalities need to take a holistic approach to evaluate urban waste and synergies among responsible stakeholders are essential to implement sustainable waste management systems. This can only be achieved through an integrated solution with the help of laws, regulations and a good mix of incentives and the help of adequate technology. Socio-environmental-technical understanding of urban solid waste is necessary (Gutberlet, 2017) but more importantly, the synergies it has with other sectors is key in delivering smart and innovative solutions that are closely linked with environmental and economic outcomes. Therefore, there is a clear need for a paradigm shift in the way urban waste is managed globally.

1 ABSTRACT

The design-led nexus approach aims to integrate design thinking and nexus thinking for urban food-energy-water (FEW) management. The approach was originally proposed in the M-NEX project with a grant by the Sustainable Urbanisation Global Initiative (SUGI) and has been developed through a series of participatory design workshops since 2018 in six consortium cities, including Amsterdam, Belfast, Detroit, Doha, Sydney and Tokyo. This article describes theprocess to develop the methodologies and applications about this unique approach, for SUGI peers to share and learn from each other. The M-NEX design-led approach is developed reflectively in a series ofdesign workshops in six target cities. Through the iterative practices in different contexts, we found that (1)the food-as-entry approach serves as a trigger to attract stakeholders' attention, and the FEW nexus provides a common ground for stakeholders to rethink the sustainability of cities by breaking down the barriers of siloed thinking, (2) the design-led method works by combining design thinking and systematic nexus thinking iteratively in visual and scientific languages, (3) the iterative application of a scientific evaluation tool, FEWprint, makes the performance of design solutions visible and comparable through communication, and (4) living labs play a key role in networking actors, practicing ideas, and scaling up to the policy landscape. We also learned that (1) FEW issues and solutions are sensitive to contexts, (2) redundant resources and the potential for improving self-sufficiency can be discovered even in developed cities by creatively integrating knowledge, technology and policy, and (3) the nexus approach is beneficialfor all actors, including governments, companies, and community leaders who are looking for collective ways of working towards policy goals such as zero carbon emissions and the Sustainable Development Goals (SDGs).

2 INTRODUCTION

Human civilization faces many threats and is on the brink of several planetary boundaries (PBs) (Steffen et al., 2015). Accelerating rates of urbanization are increasing the global demand for food, energy and water (FEW); climate change is amplifying the rate and extent over which resource degradation is occurring (Hoff 2011). As consumption levels increase, the couplings between FEW resources tighten, making theirmanagement complex and difficult. Increased productivity or efficiency in one sector often impacts the economic, political and environmental security of the whole FEW system (Bazilian et al. 2011). On the other hand, the Paris Agreement not only urges all to reduce global warming, but also points to the need to design a comprehensive transformation of urban systems and the way societies will be organized. The United Nations initiated the SDGs in whichFEW-related goals sit at the center of the vision (Liu et al, 2018). Implicitly, this calls for (a further) integration of FEW sectors to overcome siloedthinking and encourages innovative actions.

Typically, the relationships between food, water, and energy are not yet mutually beneficial. Our cities, and the systems that support them, have not been designed to address the FEW nexuses. Consumers in cities are not very much aware of the complex interrelations of food, water, and energy, and therefore will not change their behavior easily. Meanwhile, farmers in rural areas of the world produce food under increasing stresses of water and energy. Gaps exist in awareness of the roles and impacts of climate change. To date, most FEW research has resulted in assessment tools and policy proposals. The integration of food, energy and water in practical urban environments is problematic, and can be detailed in terms of three main aspects: spatial design is often lacking in FEW projects and programs; assessment tools are mostly used at the end or long after a plan or project is realized; and the involvement of stakeholders and citizens is limited to approving or declining a proposition.

Due to the connectedness of FEW in social and ecological systems, the nexus approach has been attracting attention since the first Nexus Conferencein Bonn, Germany (Hoff, 2011). The European Union implemented the Urban Nexus Project in 7FP(http://www.eurocities.eu/) from 2011 to 2014 and released a series of reports on the urban nexus, including climate change resilience, health and quality of life, and competition for urban land (Urban Nexus, 2013). The National Science Foundation (NSF) of the United States allocated a large research budget for the food-water-energy nexus and launched priority research activities in 2017. Correspondingly, Belmont Forum openeda call for the Sustainable Urban Global Initiative: Food-Water-Energy Nexus (SUGI-NEXUS, https://jpi-urbaneurope.eu/calls/sugi) with the Joint Programming Initiative Urban Europe,and consequentlyprovided grants for 15 projects at the end of 2017,among diverseapplicationsfrom around the world.

The Moveable Nexus, in short M-NEX, is one of the SUGI granted projects. It is unique in that it formalizes management tools, policy proposals, and assessment methods, both qualitative and quantitative, into physical design solutions through explicit design principles and procedures for understanding the complexity of FEW cross disciplines, fields and sectors.Since the commencement of the project, the M-NEX methodology has evolved incrementally through a series of design workshop held bi-annually at six consortium cities, including Amsterdam, Belfast, Detroit, Doha, Sydney and Tokyo (see http://m-nex.net). As a result, M-NEX has become not only the project acronym for the key concept of the movable nexus, but also the name of the output of the project, the design support platform that integrates nexus thinking into design, evaluation and engagement.This article describes the development process and the results of the project. It provides rich experience on how to incorporate the FEWnexus perspectives into urban design at the building, neighborhood, city, and regional level, to conduct collaborative urban FEW design with stakeholders and inhabitants.

3 NEXUS CHALLENGES AND RESPONSES

3.1 Complexity of FEW Nexus in Cities

FEW is a wicked problem in consideration of the complexity of cities and related to many urban problems. Food, energy, and water are highly intertwined, and even parametrically related. There are trade-offs and synergistic effects (Haase, Haase& Rink, 2014; Vogt et al., 2010). Due to the inter-connectedness of FEW in social and ecological systems, it is assumed that a nexus approach could improve sustainability in general terms, and as a result has attracted attention as a way to challenge the complex urban issues related to the status quo.However, “the application and implementation of a nexus approach is still in its infancy” (Liu et al., 2018). This is particularly true in urban contexts. Most research is focused on the supply side of the equation, namely on how to secure FEW resources in response to growing global demand. In academic research there was a tendency to view food, energy, and water separately, whether it was for resource management, production and supply, or product distribution. Thus, awareness of the nexus concept was often weak. Governmental sectors or utility agencies typically treat the problems as independent issues (Bettencourt & West, 2010). Each sector generally has its own system, making it difficult to act in a broad and integrated way. When it comes to the environment, someone would argue that considerable efforts have already been made and that efficient resource use has been achieved, so there is little room for further improvement. Citizens take thecity as a given service, as long as they pay their bills, regardless of the fact that, in reality, maintaining food, energy, and water services involves enormous costs, and this leads to severe constraints for urban sustainability.

Substantial research has been conducted on food, energy, and water (F, E and W) separately, as well as the nexus-pairs FE, EW and FW (Varbanov, 2014), and for the nexus of all three (Endo et al., 2014; Endo & Oh, 2018). Most of the research highlights scientific mechanisms of nexuses and the increase of F, E, W-related risks associated with population growth and development. Examples of typical approaches are surveys of ecological resource availability (Daher & Mohtar, 2015), urban metabolism modeling of production, consumption and disposal (Bazilian et al., 2011), shifting to a low-carbon circular economy (Bhaduri et al., 2015), and reducing external inputs from outside the region while and encouraging local production for local consumption (Siddiqi and Anandon, 2011). Limited studies have been conducted that delve deeply into the urban space and design solutions (Romero-lankao, McPhearson& Davidson, 2017).

3.2 Response from the Moveable Nexus

The goal of the M-NEX project is to develop an integrated design methodology that links complex and location-specific FEW problems at the architectural, urban, and regional scales. Instead of defining the nexus as risks, we consider that the FEWnexuses should integrate their components and by doing so, turn problems into opportunities to create a supportive environment and sustainable services. Actually, every city is unique in terms of its land, people, and relationship to the bioregion. Similarly, resource flows are different in every city around the world, too. Solutions for sustainability will be also unique in different contexts, scales, and timing. FEW provides a common playing field in the forms of buildings, transportation, green space, etc. (urban design, spatial design, architecture) for stakeholders to overcome the complexity. The moveable nexus combines the physical world in situ and cybernetic knowledge in human brains or computers into design solutions that are adapted to local contexts. To respond to the challenges and achieve the purpose, this project uses the term moveable nexus philosophically (Yan and Roggema, 2019). The multiple facets of the moveablenexus have been highlighted by the project publication (Roggemam, 2021). The following three are vitalin particular for understanding and implementation.

3.2.1 Moveable nexus thinking

The FEW nexus should be seen as a moveable nexus, which is capable of transforming its parts, its shape, and its capabilities. “The urban environment is changing all the time and, under influence of climate change, pandemics, migrationtowards the city and many more mechanisms, seems to be transforming at an ever faster pace” (Roggema, 2021). The traditional way these processes are approached is often by reducing them to simple problems for which a straightforward solution is sought. This is a misconception. For static problems a simple solution suffices, and is even needed to let society function properly. But at the same time when problems are unstructured, or wicked, a simple solution often proves to make problems worse. Thinking about the future city in terms of the ways food-energy-water generation, distribution and supply are organized may well make a difference for urban dwellers’ quality of life. The urban context is unprecedented and cannot be predicted very well. When uncertainties increase, the demand for simple responses seems to be the preferred way of treatment. This is, however, an implicit flaw, because when the complexity of the problems rises, the responses can no longer be simple. Responding as if the city is stable while in reality it is increasingly dynamic would only bring fake solutions that last for a short time. The opposite approach must be the way forward: when problems are wicked, self-organizing processes and responses that do not bring definite solutions are preferable, as they can adjust themselves as the problems change along the way. For FEWnexuses this implies that a moveable approach, in which the solutions are flexible, and benefit from all other components in the system, will decrease uncertainty, in the longer term in particular(Roggema, 2021). The moveable nexus will be presented as a way of thinking that brings this alternative within reach, with examples from around the world, in different contexts and at different spatial and temporal scales. As befitsa moveable philosophy, all perspectives can be used elsewhere, and the knowledge is meant to move around. This inspires alternative way to collect the knowledge and create solutions that adapt to changing conditions.

3.2.2 Design-led nexus approach

The integration of food, energy and water is not yet mainstream, and there is no established methodology to practice the nexus approach (Yan and Roggema, 2019). It was not common in urban planning and design because of the complexity of the problems per se, the uncertainty of outcomes, and the difficulty of communication between scientific research and design practice. On the other hand, design is by nature a trans-disciplinary approach to problem-solving, which draws upon logic, imagination, intuition, and systemic reasoning in order to explore potential innovative solutions to problems (Kimbell, 2011). Designers explore concrete integrations of knowledge that will combine theory with practice for new productive purposes (Buchanan, 2010), integrating the opinions and needs of multiple stakeholders. In spite of the romantic image that design is a highly personal process, in most cases design proposals are in fact the culmination of shared knowledge and consensus on a specific issue (Kimbell, 2012).

These advantages make a design-led approach particularly appropriate to address wicked problemson the philosophy of moveable nexus thinking. It is extremely useful, as it is able to create something out of nothing that existed before, presenting opportunities to be continuously and collaboratively adaptive, as a city, as a landscape, and as a society(Roggema, 2021). This is particularly true in participatory design where design proposals are the result of professional design activities and communications with a variety of stakeholders.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

With this concept, the M-NEX project developed a design-led nexus approach for urban FEW designs. This approach organizes the sophisticated design process into a series of charrette workshops, an intensive form of design activity often adopted in design practice (Yan and Roggema, 2019). It offers a demanding process with expectations about delivering innovative solutions within a tight time schedule. The need to present the outcomes visually creates pressure to deliver content that is aspirational. The step-by-step design process gives a clear guide for performance and turning inspiration and creativity into regional-to-local design propositions that belong together. Participation and communication provide opportunities for stakeholders to envision and create a new perspective on the future of a geographical area from diverse perspectives.

3.2.3 Moveable nexus platform

Making the workshops workable requires the support of data, informationand communication tools. The M-NEX project planned the moveable nexus platform with three modules: design method, evaluation tools, and participatory mechanisms. Each module consists of the following functions (Yan and Roggema, 2019).

Design method

The design method provides guiding procedures to explore solutions with stakeholders. The procedures are composed of the following steps.

(1) Inventorying FEW-related existing or potential resources and availability of space for urban agriculture, including rooftops, vacant houses, and abandoned, inadequately used or vacant lands

(2) Designing solutions to improve the efficiency of land and space use for food production and ecosystem services with less energy and water consumption by integration of FEW technologies and knowledge

(3) Composing the nexus matrices that mobilize the material and flows of resources cross sectors and disciplines in the social-ecological context

(4) Evaluating the environmental costs and added benefits of solutions through the enhancement of spatial, temporal and service connections among specific social-ecological systems

(5) Delivering the alternatives of solutions and reiterating the design process with stakeholders

This is an iterative and learning process with stakeholders working together. The inventory includes social, financial, and industrial aspects. The mobilization of resources implies the activation and connection of existing and potential capital across industrial, administrative and academic boundaries, with more flows and services.

Evaluation tools

The evaluation of design solutions is a tricky issue. There exists a long list of indicators to assess the impact of human activities on the environment, such as the most typical ones, which include food mileage, CO2 emissions, virtual water use,and the ecological footprint (EF) (Wackernagel & Rees, 1998),etc. Inspired by EF, we developed an indicator we call FEWprint which expressesin terms of land area asthe sum of (1) the land area needed to meet with the demand for food, energy, and water, and (2) the forest area to absorb the corresponding CO2emissions related to FEW resources and services. FEWprintwill be applied iterativelythrough the design process. The output can expressthe existing environmental loadof the FEW demand as a baseline, or the effects ofFEW production and creative design for FEW supply at local level within a household, a street block, a neighborhood, or a city.Such a simplified indicator is extremely useful to assess the performance of design work under different scenarios and alternatives. Stakeholders can understand the environmental costs, the trade-offs and the synergies of different solutions, and eventually rethink the inter-relationships of their behaviors.

Participatory mechanisms

The engagement of multiple stakeholders is conducted through a series of design workshops in the moveable nexus approach. There could be four types of partners: intermediate support organizations, the local community, experts in spatial planning, and public or private sectors.Each partner potentially brings specific resources and advantages, such as physical space, skills, knowledge, financial or regulatory options. During the workshops, design experts visualize resources and produce solutions. The local community can gain an awareness of the issues and co-create the shared values. Private or public sectors might be inspired and then turn the plan and design into policy and business actions. Our experience has told us that intermediate support organizations such as an urban living lab driven by local actorscan play a key role to connect stakeholders together (Yan and Roggema, 2017).

In summary, the moveable nexus platform is a technical support for moveable nexus thinking. The design-led moveable nexus approach is a process to develop the platform through informed design workshops. Urban living labs are the physical places to accommodate the activities for engagement. Consequently, the moveable nexus thinking, the design-led nexus approach, and the moveable nexus platform in cooperation with an urban living lab commonly form the framework and methodology of the M-NEX project.

4 IMPLEMENTING THE MOVEABLE NEXUS

4.1 Establishing Living Labs

The M-NEX project has unfolded at six living labs, including Amsterdam,Belfast, Doha, Detroit, Sydney, and Tokyo-Yokohama. The six cities differ in terms of geographical features, bioregions and societal conditions, but all of the cities are mature and share several concerns in terms of sustainability in their urban areas. Yan and Roggema (2019) reported on the geographical features, bioregional differences, and social themes of every study area. Each city has developed the urban living labin flexible ways. It can be initiated by the research team originally or be a joint facility with stakeholders such as the WISE Living Lab in Tokyo-Yokohama (http://sankaku-base.style).

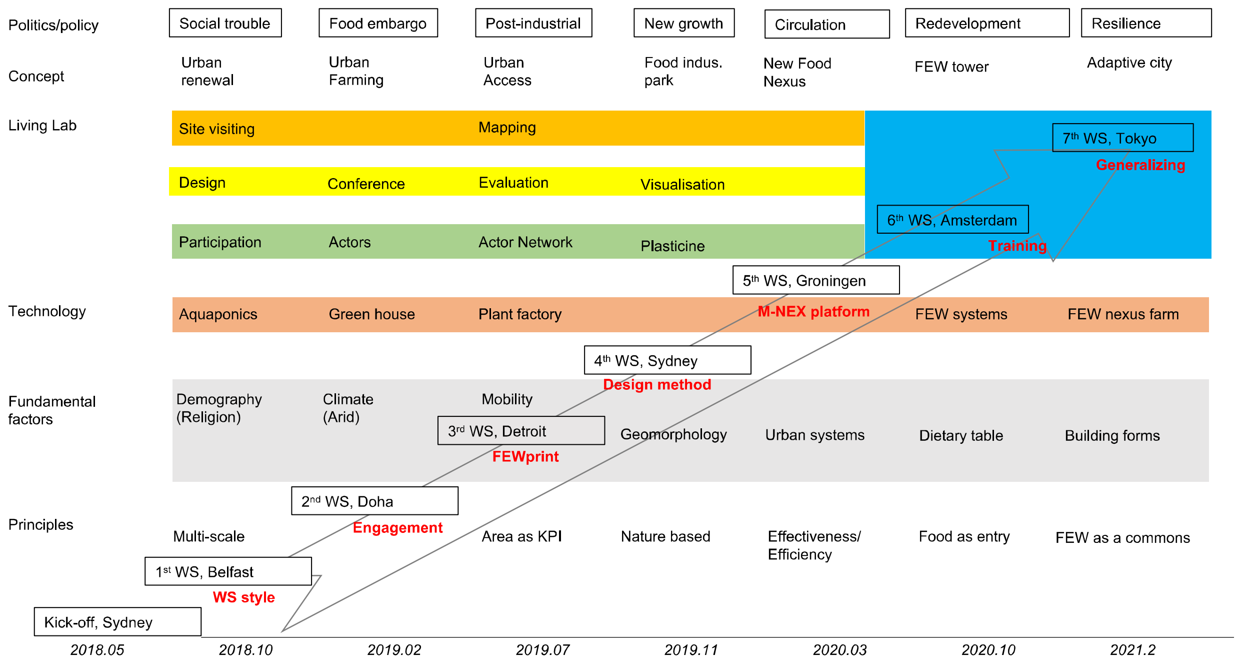

Fig. 1. Incremental project workshop (WS) and results

4.2 Managing the design workshops

The key characteristic of the M-NEX project wasto develop expertise as we harvested knowledge through a series of international design workshops organized at the respective living lab by the individual partner in each of the consortium cities. Every partner country was scheduled to organize aone week-long design workshop with local stakeholders and communities once through the project period. The aim of those workshopswas to co-design a solution for the project site and develop additional knowledge for a specific theme, which then feeds back into the methodology and builds up the evaluation tool (FEWprint). After the first international workshop, the shared knowledge was applied in local workshops in the partner countries for local partners, without international participation. The enriched methodologyat the local level and the advanced evaluation tool was then used as input to the next international workshop in the next partner country. The same process occurredevery six months, following a rotation schedule.Before and after each international workshop, each team held local workshops, practice the learnt method and tools at the local level, and provide feedback to the next international design workshop.By the end of the research project (36 months in total) the design-led meetings and workshops hadsuccessfully been held to harvest the ways of approaching and appraising the applicability. The process and results of the workshops are illustrated in Figure 1, which depicts the understanding of how the design-led approach works overtime. The advantage of this management style is the rotation of method development through practice along with partners and participants.

4.3 Results

As shown in Figure 1, following the kick-off event in Sydney, the first workshop was held in Belfast and focused on creating an initial vision for technical food systems in a post-industrial city. The workshop established the participatory style for running the design workshop. The second workshop, in Doha, organized a comprehensive conference with various stakeholders in food and urban farming to look at how to secure the food supply of a city under a food embargo. The workshop highlighted the importance of networking and engagement of stakeholders with a living lab. The third workshop took place on food access and security in Detroit, a post-industrial city with large amounts of vacant land in the urban center. The research conducted by the Detroit team on FEW material flows and actors on urban food issues initiated the development of FEWprint and the visualization of actors. The fourth workshop, in Sydney, worked on the design of a food industrial park near the planned new airport. The design workshop emphasized the development of the emerging area in harmony with natural ecological systems through the iterative design process. The fifth workshop, originally scheduled for Tokyo, was relocated to Groningen because of the nascent outbreak of COVID-19 in the Asian region. The design work and trial of FEWprint tools at three scales (farmland, campus, and region) inspired discussions on urban FEW circular systems. The sixth workshop, hosted by the Amsterdam team online, proposed a redevelopment plan ofthe harbor district based on a pig firm. A technical training session was also organized by younger researchers to apply FEWprint in six cities. The final design workshop was organized virtually by the Tokyo team. The workshop integrated the expertise developed so far and summarized the nexus approachfor designing adaptive cities in response to climate change. This process was repeated bi-annually, with seven international workshops held (after the kickoff workshop) over the course of three years. Each team had the obligation to host one international workshop over the period. Other organizations participated and cooperated. Consequently, the knowledge obtained at each workshop was integrated and provided as expertise and solutions from the M-NEX Project at each level, from building to neighborhood, city, and region.

5 FINDINGS AND DISCUSSION

5.1 Moveable nexus as a learning process

The project took the complex sustainability challenges of the participating cities, and communicated FEW design solutions in concrete, visual, and physical ways to stakeholders and residents through a series of design workshops. The knowledge developed in each workshop was added to the M-NEX platform and used to gradually enhance the tools. It was then applied to other cities. Each team brought its most urgent topics to the international design workshops, and the teams worked together to refine and build common design methods, evaluation tools, and cooperation platforms. For example, the UK team (Belfast) worked on the design of food factories, while the Dutch team (TUD) focused on energy planning in the FEWnexus.Ultimately, we delivered the research findings, policy recommendations and technical innovations, such as implementation of FEW at the University campus (Doha), revitalization of a post-industrial city (Detroit), and future FEW strategies for consumption-oriented cities (Tokyo-Yokohama, Sydney). The knowledge and solutions developed in these themed workshops were then subsequently integrated finally at three different scales: building, neighborhood and city. The teams also brought what they learned back to their cities, applied them in practice locally and undertook actions toward the next international workshop. This process deepened the understanding of FEW issues and promoted consensus on actions and plans for each city. All of the teams learned from each other and studied the potential to incorporate FEWmanagement into their own cities. The living labs have worked jointly in the six urban areas, and shared design methods to build co-creative platforms, as well as evaluation tools and participation frameworks. Hence, the moveable nexus was a learning process. The series of design workshops provided input on design, evaluation and participation through the generated and distinctive platforms to the case study projects managed in each partner city. The entire project travelled iteratively along the project partner projects, while developing new knowledge and delivering designs at different scales in each partner city, and then integrated the methodologies, tools and participation at the end.

5.2 Principles forthe Moveable Nexus approach

Common factors and principles were observed by obtaining new knowledge and creating solutions for problem solving through the process as shown in Figure1. Some of the key points are highlighted below.

5.2.1 Food as entry point

The food-energy-water nexus is a wicked problem in cities. To simplify the problem, we used food as an entry point in organizing workshops and eliciting solutions. This was considered from both the demand and supply sides. From the perspective of demand, (1) food is essential to survive, (2) food is coupled with energy and water, (3) the availability of food is an issue of personal mobility as well as a deliverable urban service, (4) the quality of food is a barometer of the quality of life for a family or a community, (5) food is meaningful as a way to enjoy life and look for new opportunities, and an important consideration with regards to health, environment, and mobility, and (6) food culture varies by nation, context, and personal preference (i.e., vegan, vegetarian, meat-eating, etc.) and each results in a different environmental footprint. From the perspective of supply, (1) food is part of a complex supply and demand network within cities, (2) food systems are sensitive and change over time through processes such as urbanization, (3) food services are one of the largest and most complex businesses in cities, (4) food is a hot topic in the environmental realm, taking many forms such as organic food, slow food, food loss, and food waste, etc.The choice to use food as an entry point helped to facilitateour approaches to stakeholders.

5.2.2 FEW as a commons

Generally, the supply of and demand for food, energy and water are managed separately by each sector. While industry and government work hard to secure the life supporting services, FEW is often ignored in urban management. Architectural and urban designers tend to think that FEW is a given output of the market or from public services, and reserve little room for alternative ways to supply the systems in place. Only recently, the movement toward SDGs has been changing the atmosphere in academic and management realms as the food-energy-water synthesis is emerging as a key leverage tool for urban sustainability and social equity. Research indicates that FEW access and consumption emit almost 70 percent of CO_2 emissions at the level of individual livelihoods (Dhakal, 2020). Food can be used as a lens to consider social, economic and environmental relationships between the demand and supply in cities. It can be a catalyst to rebuild the relationship between production and consumption of FEW in social-ecological systems. We found that FEW has the potential to be a commons for silo-based stakeholders to sit together at the living lab and think about services and infrastructure collaboratively. This significantly supports the initiative of the SUGI call (https://jpi-urbaneurope.eu/), catalyzing stakeholders to take actions on sustainability issues.

5.2.3 FEWprint as KPI

FEWprint is a tool developed by the M-NEX team for interactive design. It can be considered as a subset of the ecological footprint (EF). As mentioned above, as with EF, FEWprint is calculated as the land area to produce food, energy and water services for a specific social or physical unit and the equivalent forest area required to absorb the correspondent CO_2 emissions through the production, transportation and consumption of FEW services. A social unit consists of an individual, a household or any group of people, while a physical unit is defined either as a detached house, a single unit in an apartment, a building, a neighborhood, or a city. This practice enables FEWprintto be scaled upfrom the building or street block level to the urban or regional level forpolicymakers.

How to deal with changes in FEW was the key issue ofthe moveable nexus thinking. FEWprint can be used as a key performance indicators (KPI) to evaluate the effectiveness of design propositions under various scenarios: for instance, business as usual (BAU), incremental change, and transformational change, adapting to climatic and demographic changes in comparison with the currentcondition as a baseline. Typically, the space reserved for producing or managing FEW components locally within densely built-up urban environments is very limited while more opportunities are available in suburban or extra-urban zones. The situation is changing as a result of a revolution in the production of renewable energy such as photovoltaic panels. Self-produced, or locally-produced and harvested food, energy and water could shorten the distance between demand and supply, eventually reducing the intensity of FEWprint where that gap is shortened. Therefore, FEWprint is useful to evaluate not only the consumption intensity of FEW but also the effects of efforts to reduce the intensity. By using FEWprint, the M-NEX method can (1) redesign the relationship between demand and supply, (2) reassess the costs and benefits of FEW resources and services, and (3) rediscover the opportunities in cities for innovative FEW management in the future.

5.2.4 Technological innovations

Technology playsa key role in solving problems toward sustainable urbanization by improving productivity, reducing carbon emissions and creating jobs. One of the missions forthe M-NEX project was to integrate the fragmented knowledge and technology into the spatial arrangement of design works. The propositions ofdesign workshops and the activities at the six living labs have intensively reflected this mission. The choice of technology is a selective decision based on local natural and social-economic conditions. For instance, the Belfast team proposed urban vertical farming by aquaponics to revitalize unused industrial buildings; the Doha team invented a semi-underground greenhouse to prevent overconsumption of fossil energy; the Detroit team designed urban agriculture parks with ventures that are developing plant factories underground and on the ground; the Sydney team proposed a food industrial park near a new airport to serve an Asian market; the Amsterdam team designed a food tower that produces diverse food products with a significantly reduced FEWprint; the Tokyo team proposed a renewable energy and hydrogen-based home FEW nexus firm for a large number of detached houses in the suburbs of Tokyo.No one solution fits to all ofthe cities. Adoption ofthe technologies should be based on the understanding of the political visions and the fundamental factors of each study city.

5.2.5 Context dependency

Regarding the urban FEW design, we should always think about how we can input contexts into the design process. As shown on the top of Figure1, each city had distinct concerns and the priority of problems to discuss and the solutions were totally dependent on the socialeconomic and natural conditions of cities.Thosecontexts are absolutely crucial to understand, because they will directly impact the ability to design in any given situation. There is a kind of demographic dimension of contexts to this too. It may beeasier in the Netherlands to propose an all-vegan diet in conversation with stakeholders than in the United States, for example, and practices will differ at the individual and cultural level in Qatar versus in Japan. It is then a challenge to implement the policy goal at a community level. Although the acceptance of this kind of global policy may be distinct from countries and cities, a common indicator like FEWprint or a common language likethe SDGs does help localizethe moveable nexus approach properly into the distinct context.

5.3 M-NEX, the Developed Moveable Nexus Platform

Throughthe processandabovefindings, theprojectteamdevelopedthe designsupportplatform, M-NEX,asshown inFigure2. This diagram illustratestheessenceofthedesign-lednexusapproach. The key concept of the platform, as indicated at the top of the diagram, is land area to be expressed as FEWprint, the key performance indicator to measure the resource-use efficiency and design solution effectiveness. It first accountsfor the land area required to meet the demand for FEW and the forest area to absorb CO2 emissions in FEW resources and FEW services asFEWprint baseline. Then, the area existing and to be created to supply FEW resources and services, as well as to absorb CO2 emissions, are accounted for again. By increasing FEWprint NEW and reducing FEWprint NOW, we can shrink the range needed to meet the FEWdemand and supply.

The design method under the area concept is composed of three phases, with nine steps as a whole, and each phase is supported with sophisticated intelligence and ICT tools. The first phase with three steps is to explore the site at different scales, understand the policy context and define the design concept. FEWprint is calculated as a baseline here. The secondphase iterates design and evaluation with FEWprint under different scenarios and adaptive strategies. Basically, all situations and technologies have the same basic elements that can come into this process, such as new energies, vertical agriculture, or green infrastructure, etc. The third phase is participation and co-creation with players at a living lab. The FEW nexus provides a commons to bring the stakeholders—from the upper stream such as utility companies to the lower stream such as grocery shops and inhabitants—to the living lab.

This platform is moveable and flexible for teams to modify for each of their specific contexts and policy issues, ranging diversely from aspects such as carbon neutrality and SDGs to the circular economy. The comparisons can be most meaningful between different adaptive strategies. By applying the platform, we can compare the outputs in the cities, or compare and contrast different approaches in different cities; for example, a business-as-usual strategy versus an alternative proposal within a given city. We can identify the role of an individual household, or an individual stakeholder. We can examine a type of housing, versus a neighborhood organization, or the precinct organization that allows for the institutionalized dimension of the system to be spatialized in the city, or a more general comparison that we would see different patterns across these cities. The comparisons across cities will be more about context differentiation, and the focus could be on how the approach and the tool can be utilized in different contexts around particular technologies and scalar differences.

6 CONCLUSION

M-NEX was designed to have an impact across a variety of scales, stakeholders and locations. The decision-making tool and platform weredeveloped through intense community-based workshops in six locations around the world. The research team visited each location to collaborate with local stakeholders from various sectors in urban living labs to address and formulate a strategy to tackle local FEWproblems. This approach ensured an applicable strategy that provided value for the local academic community, citizens, end users, and commercial parties. The outcomes of each location were analyzed and combined to refine the moveable nexus approach. This process of refinement has helped the output of the moveable nexus platform M-NEX to gradually mature. The iterative design process developed within the project integrated FEW systems, participatory design, FEWprint evaluation and communication formats, and presented a new direction for urban design processes. As the work is disseminated, we expect these methods and processes will help to shape future urban design practices, both academic and professional.

7 ACKNOWLEDGEMENTS

M-NEX is a grant project of the Collaborative Research Area Belmont Forum (No. 11314551) implemented by a consortium of partners from Japan, including Keio University and the Institute for Global Environmental Strategies; Qatar University; University of Michigan; Delft University of Technology; Queens University Belfast, and MacCreanor Lavington. Local governments, companies and communities were involved in the activities of the national teams. We are grateful to JPI Europe Urban for initiating the Sustainable Urbanization Global Initiative—Food-Water-Energy Nexus and making the M-NEX project possible.

1 ABSTRACT

Spatial justice is a term that advocates for the equal distribution of resources and privileges that are not easily accessible by the commoners due to various reasons such as financial constraints, poor education among others (UN-Habitat, 2018). Choosing Lamu Town as a case study, one of the best preserved Swahili settlement would best bring out how spatial justice would play a significant role in the preservation of cultural heritage. The term commoners in this research refers to the indigenous people. With the promising future of Lamu since its initiation of Lamu Port – South Sudan – Ethiopia Transport (LAPSSET) among many other development projects that are neighboring the town, the threat to the heritage site due to uncontrolled developments expedites. The role of urban planning in spatial justice applying in Lamu Town would be to provide a sense of acceptability, support, compliance and suitability for the commoners in Lamu. Putting in mind the boundaries of sustainability in cultural preservation for future generation. The research employed qualitative study methods, such as; conducting primary dataset that includes online survey questionnaires with 40 participants and 10 physical survey questionnaires, interviews with 5 local experts, photo observation and on desk survey. According to the data collected so far, there is a larger concern for the declination of cultural heritage due to urban developments. Secondly, all aspects such as land, housing, water, electricity and waste system are inadequate for the rapid growth of population.To conclude, the contribution of this research is to highlight on the importance of spatial justice and its role in safeguarding cultural heritage that not only plays a significant role in economy but as well as protecting a far greater value which is identity.

Keywords: Cultural heritage, spatial justice, urban planning, sustainability

2 INTRODUCTION

Lamu Old Town is located on a small island off the north coast of Kenya, as seen in figure 1. Its neighboring towns such as Shella, Pate, Siyu and Faza are as well among the best preserved swahili settlements, each with a distinctive aura along the East African coast (Marguerite Y. 1979) whose cultural practices relate to the teachings of the Islamic religion. Lamu Town has the largest populations among the neighboring towns hence choice of the case study. The Old Town was enlisted as a World Heritage Site in 2001 by United Nations Educational, Scientific and Cultural Organization (UNESCO) due to its realization of its unique cultural heritage and its characterization of indigenous building technology that was borrowed from different traders and colonists such as the Indians, Arabs and Portuguese. The Old Town is a historical site with a good number of still surviving 17th and 18th century stone houses that are about 700years of age or more and which had been screened from modern development pressures (National Museum Heritage Act, 2006. Cap 216).

However, as a result of Lamu Port – South Sudan – Ethiopia Transport (LAPSSET) near Lamu town that consists of several other infrastructural components such as: a new modern port of 32 berths, planned new transport infrastructure containing an airport, railway line, an oil pipeline and a good number of highways. Among other developments such as metropolis city with the capacity to take in 1.1 million people see figure 2. All the developments mentioned above happening at the node of Lamu World Heritage Site. Where regardless of its protection by a number of organizational bodies would be impacted. Its effect already being felt. Therefore increasing the urban challenges facing Lamu Town and the efforts of conservation of the historical site.

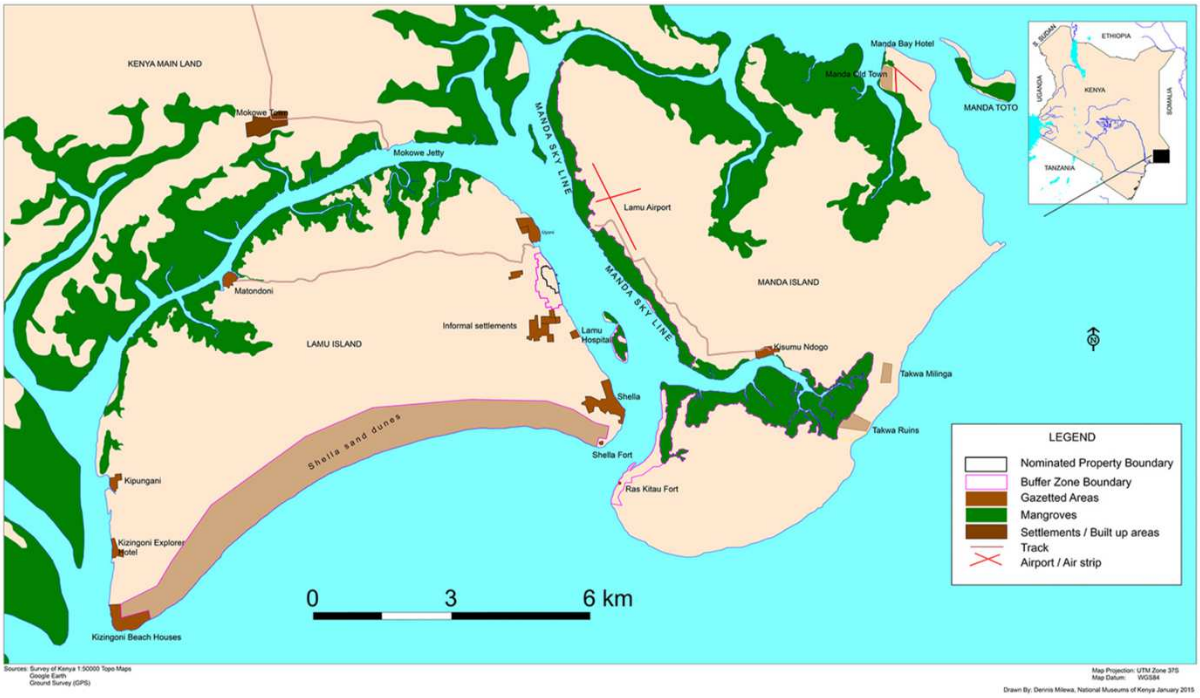

Fig. 1: Location of Lamu (Source: National Museum of Kenya)

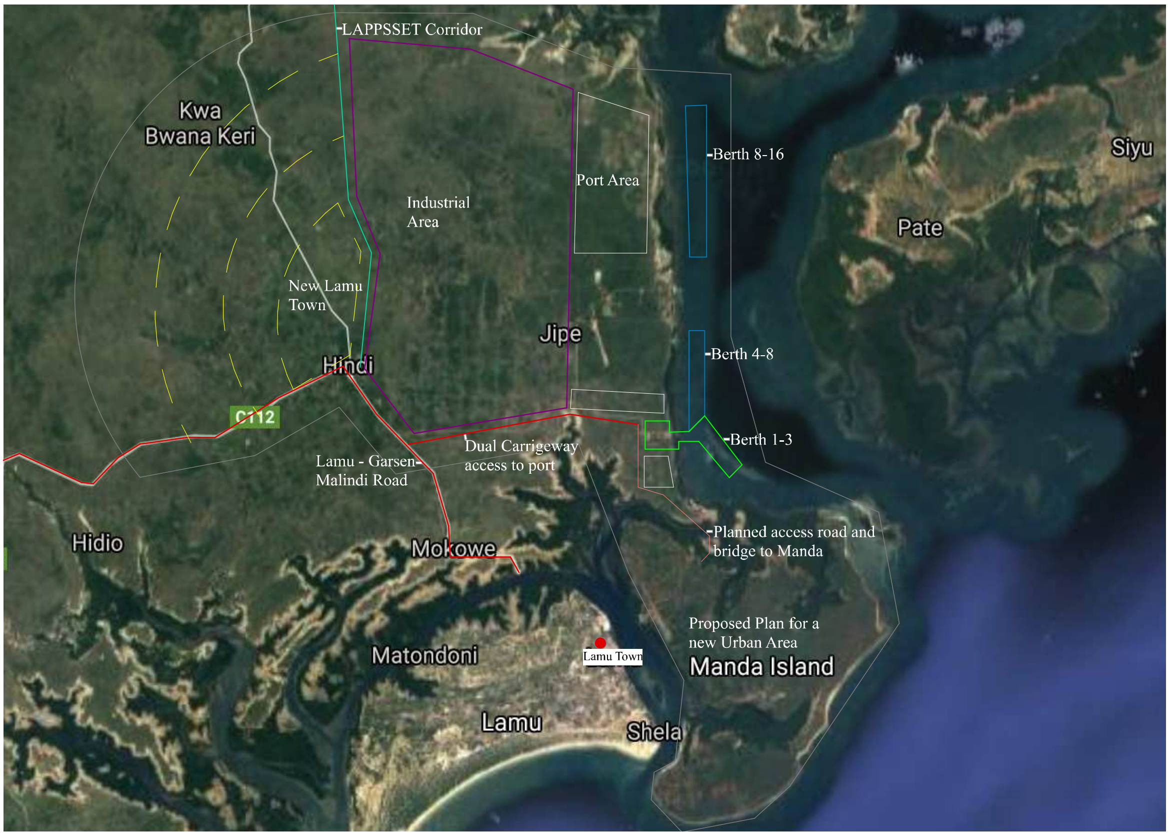

Fig. 2: Upcoming developments neighbouring Lamu Island (Source: Edited from Google maps)

Experts say that regardless of efforts to prevent any kind of development relating to the port, the town will undergo development whether intentional or not (World Heritage Committee, 2015). Through projection of population estimation between the year 2009 - 2025, it was computed that by 2025, Lamu Town population would be at 12,242 (Lamu County Spatial Plan, 2017). A census was conducted in 2019 and the population was at 25,385 surpursing the computed population of 2025 by twice the estimated figure. Thus proving that Lamu Town is at a greater risk than anticipated. The emergence of such pressures will have a profound effect on the Old town. With an increase in urban pressure imposing on the commoners, resources such as land, housing, water, electricity and sanitation does not meet the demand of the rapidly increasing population.

Moreover, most commoners finding the living conditions becoming harder especially after being affected by the decline in tourism and the fishing industry as a result of the port development.

2.1 Physical Context

Lamu Old Town is the oldest and best preserved Swahili settlement on the East African coast. According to (Lamu County Spatial Plan, 2017: pg.11), about 65% of the physical structures are in good condition with only 20% being in need for minor changes and that of the remaining 15% may need total restoration. The majority use of the buildings being commercial, public purpose or residential. The town is characterized by narrow intertwining streets where most are less than an arms stretch allowing for pedestrial movement and donkeys in most streets, in some the pedestrians have to pave way for the donkeys to pass.In 2013, through the new County Government Act, Lamu was urged to prepare a spatial plan showing the Land use zones for its future vision and figure 3 shows the proposed Land-Use-Zones of Lamu Island by the County Government in 2013 that is yet to be implemented.

The vernacular architecture of the town depicts a two-storey building with a terrace constructed from local resources and with local traditions, often with wooden facades, and overhanging eaves. The carvings in the wooden doors are highly decorated, reflecting floral patterns. With the modern material and technology most upcoming buildings use this technology as it is cost and time efficient.

Moreover, Lamu town having been known of a place that offers tranquilty due to its minimal motorized vehicles that only served as a garbage collector, ambulance and policing that was only used on the seafront. Major transport used was donkeys and carts where goods are moved through the narrow twisted alleyways of the town. Until of recent times, motorbikes are now mostly used as a means of transport for people from one place to another. This has brought debates on whether they should be banned, but as of now, thereis no control on the motorcycles. Moreover, the streets not only serve as a space for movement but rather as a socializing space where youth and elders engage in talks and even play board games thus integrating both tangible and intangible attributes that bring out its outstanding universal value as a Heritage Site. On the other hand, the shore line of the sea is used a space to conduct businesses as well as a space that allows people to enjoy the view of the ocean. Over time, the seafront has been used for cultural festival activities that happen each year attracting visitors from different parts of Africa, Gulf and other parts of the world. In addition to this, the Town has a common square that acts as the center of the town, where auctions, political and social functions take place. Neighboring the square is a market which plays a significant role in the community’s identity.

2.2 Economical Context

Over the century, the main economical source of income of Lamu is tourism and fishing. Other sources being furniture making and farming. The two major source of economy has proven to not being reliable due to security threats by terrorists, change in climatic conditions and the new port development affecting the nearby fishing grounds where local fishermen with insufficient fishing equipment greatly suffer. The town has continuously been undergoing economical decline threatening the cultural heritage due to displacements of its commoners in search of jobs, better education and living conditions.

2.3 Culture and Lifestyle

The culture and lifestyle of the commoners in the Old Town remains conservative and responds to the Islamic teachings as majority of the people are Muslims. Lamu, has ever since been a center for Islamic knowledge from 19th century by the arrival of the Jamil al Layl Sharif, Habib Saleh from Comoro Islands, who is said to be a direct descendant of prophet Muhammad (Paul G. 2018). Each year Lamu holds three festivals one celebrating the birth of prophet Muhammad known as ‘Maulid’ and the second one the cultural festival showcasing the culture of the people of Lamu and sport games from donkey racing to boat racing and dhow racing on every new year’s day. According to Sheriff, Islam played a role in the Town’s evolution in their planning. He further states that Islam provided administrative, legal, educational and spiritual structures that allowed for the expansion of the Swahili city states (Sheriff, 2010: 239). The lifestyle of its people is mostly simple and as result of the climatic conditions, the working clock starts off early in the morning and stops slightly after noon then resuming in the evening after their evening prayer ‘asr’.

3 RESEARCH METHODOLOGY

In line with the research goals that aim at expounding on challenges facing the commoners in relation to the unmanaged urban development on the heritage site, the research strategy used is based on qualitative research methods.A variety of sources were used to obtain data for triangulation purposes. Thus allowing for proper assessment of different sources of information to investigate concepts on the fact that a consensus of the findings will producebetter results. The figure belowshows the outline of the dataset.

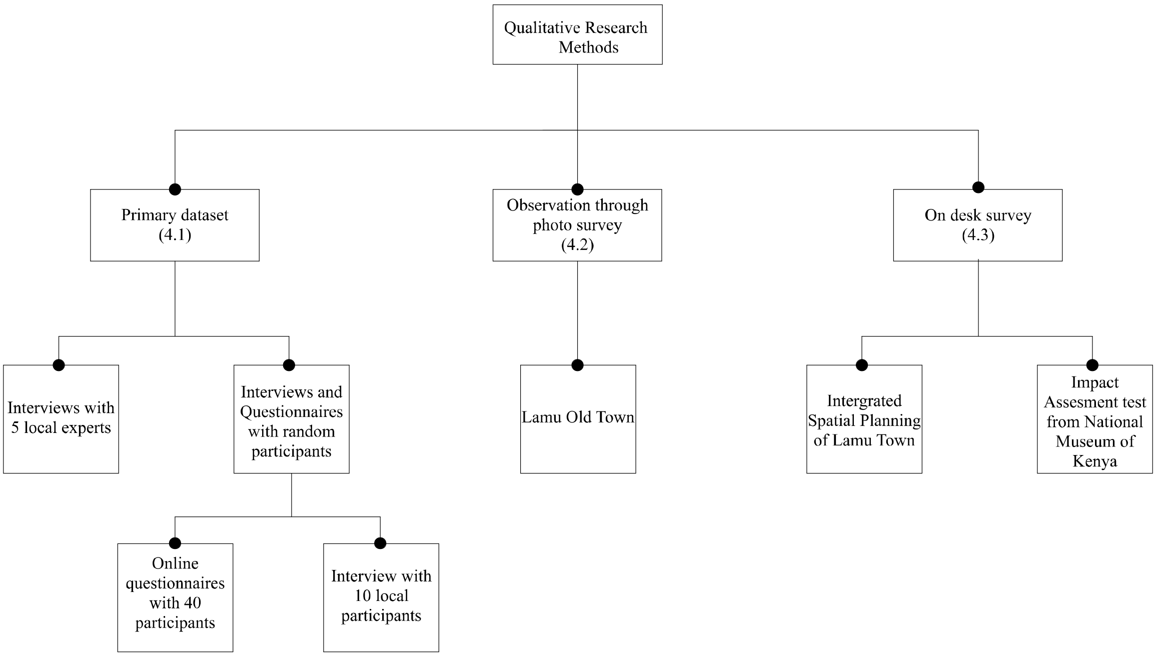

Fig. 3: Diagram showing qualitative research methods

Structured question	Respondent 1	Respondent 2	Respondent 3	Respondent 4	Respondent 5
What are the positive and negative effects of development in Lamu town	**Positive:** -The money harnessed if properly managed could help the heritage site -Improvement in all sectors; health care, security and infrastructure **Negative:** -Spontaneous, poor management -Inadequate sewer system -Modernisation -Issue of purchasing power affecting the locals	**Positive:** -Employment -Improvement in socio-economic development **Negative:** -Depletion of natural resources -Food insecurity -Displacement of indigenous people -Heavy impact on fishing industry -Rapid demographic change	**Positive:** -Improvement in building technology **Negative:** -Traffic -Sporadic development -Loss in heritage -Insufficiency of land -Land conversion	**Positive:** -Employment **Negative:** -Decline in tourism -Change in ecosystem -Loss in heritage -Land conversion -Pollution	**Positive:** -Employment -Improvement in infrastructure such as the expansion of market building, paved road on seafront **Negative:** -Insecurity -Effect on torism -Pollution
Which aspects (water, electricity, land, housing & transport) meets demand of rapidly increase in population of Lamu Town	-Non meets the demands	-Non meets the demands	-Non meets the demands	-Non meets the demands	-Non meets the demands
If funds were made available for future development, which area should it be focused on	-Disaster risk management to be implemented -Diffusing pressure by buying land and creating space -Improvement in services	-Environmental friendly technology -Fishing industry -Alternative livelihood projects -Improving solid-waste infrastructure	-Water to be looked at as a necessity -Public utilities -Constructing a different path for motorist -Designing of the seafront	-Landscaping -Improvement of facilities -Improvement of street lights -Designing of the seafront to represent culture	-Fishing industry -Improvement of facilities -Improvement in tthe education sector
How can funds be raised	-County government of Lamu -Donors	-Donors, UNICEF -National Museum of Kenya -Bilateral organisation	-Donors -UNESCO -Lamu County Government -Mosques	-Donors -UNESCO -World Heritage Bank	-Donors -UNESCO -NGO's
What roles should residents play in helping to plan for a viable development	-Community led initiative centre -Learned community member to give back	-Request support ffrom donors	-Sensitization of community	-Creating awareness -For the learned to give back to community	-Community led initiative centre -Creating awareness

Table 1: Response from local experts

4 RESEARCH FINDINGS

4.1 Primary dataset

An empirical data was conducted with 5 semi-structured interviews with local experts on heritage conservation and urban planning (Fig. 3)sampled by selecting them from public sector (Table 1). This assisted in providing an in-depth exploration of emerging issues, observation and documentary evidence. Interviews was sought through the respondents perspectives on issues concerning the heritage and urban planning. The interview schedule consited of five main questions that aimed at effects of development on a heritage site.

Respondent 1: Mr. Mohammed Mwenje, Curator of the Lamu Museum, National Museum of Kenya

Respondent 2: Mr. Mohamed Baishe, Director of Environment and Natural resources, Lamu County

Respondent 3: Arch. Omar Saggaf, County Architect and Head of Public Works

Respondent 4: Mrs. Husna, Lamu Museum

Respondent 5: Mr. Maawya Farid, Commisioner of Lamu County Service Public Board

An online questionnaire with 40 participants at random was conducted, majority of the count 23 being of the age 25-40, 18 being of the age 40-60, 4 above 60 and 4 between 18-25 years. 73% of which are residents of lamu and 90% being indigenous people of Lamu. On the level of education, 88% had an educational achievement of college/university, 6% of secondary certificate, 2% each of primary certificate, technical school and 2% responded non of the above. Under empolyment, 42% of respondents were working in pubilc, 35% in private, 2% industrial and 21% in other forms of jobs. This type of online questionnaire had an advantage of getting the response from educated people yet a disadvantage of getting response from participants who found the choice of language challenging. I therefore conducted 10 interviews with the locals by using the local language and their response was included in the illustrations below.

QUESTION	RESPONSE
What aspects will be affected by development	Positive and negative aspects that will be affected by development	Migration influx affecting the cultural heritage Competition of job opportunities with non-locals Concerns that the locals will not be able to cope with the socio-economic change Positive aspect that it would improve the activities and the economic growth Decline in the fishing industry Fear of increase in marginalization, exploitation of locals and tribalism Insufficient lands and land conversion Religious and cultural animosity Increase in pollution

QUESTION	RESPONSE
What aspects of culture should be preserved	Other important aspects	Traditional mode of transport which is the use of donkeys, walking and use of carts for heavy goods Fishing industry as a key role in the heritage of lamu Protection of intangible cultural heritage Protection of historical buildings and sites Protection of mangrove forests
Do you believe in integrating culture and development as a way of providing quality of life and fulfill future needs of the town

4.3 On desk survey

4.3.1 <u>Proposed spatial plan of Lamu Island</u>

As Lamu is heading towards a new era of large-scale development and infrastructure investment, mostly as a result of the multi-million dollar LAPPSET project. Just as these developments could generate substantial economic and social benefits, they as well could pose a threat when not managed properly. Responding to the facts, Lamu County Government developed a county spatial plan in 2017 to guide the development, use, demacating the conservation zone among other resources in the next county that was meant to last for 10 years. The spatial plan is yet to be implemented. Figure 9shows a proposed Land Use Zones in Lamu Island by the County Government. The Old Town has no direct connection with the mainland and through studies it has been noticed it would improve the economy by just providing the access as seen in fig. 4 hence it was proposed in the spatial plan.

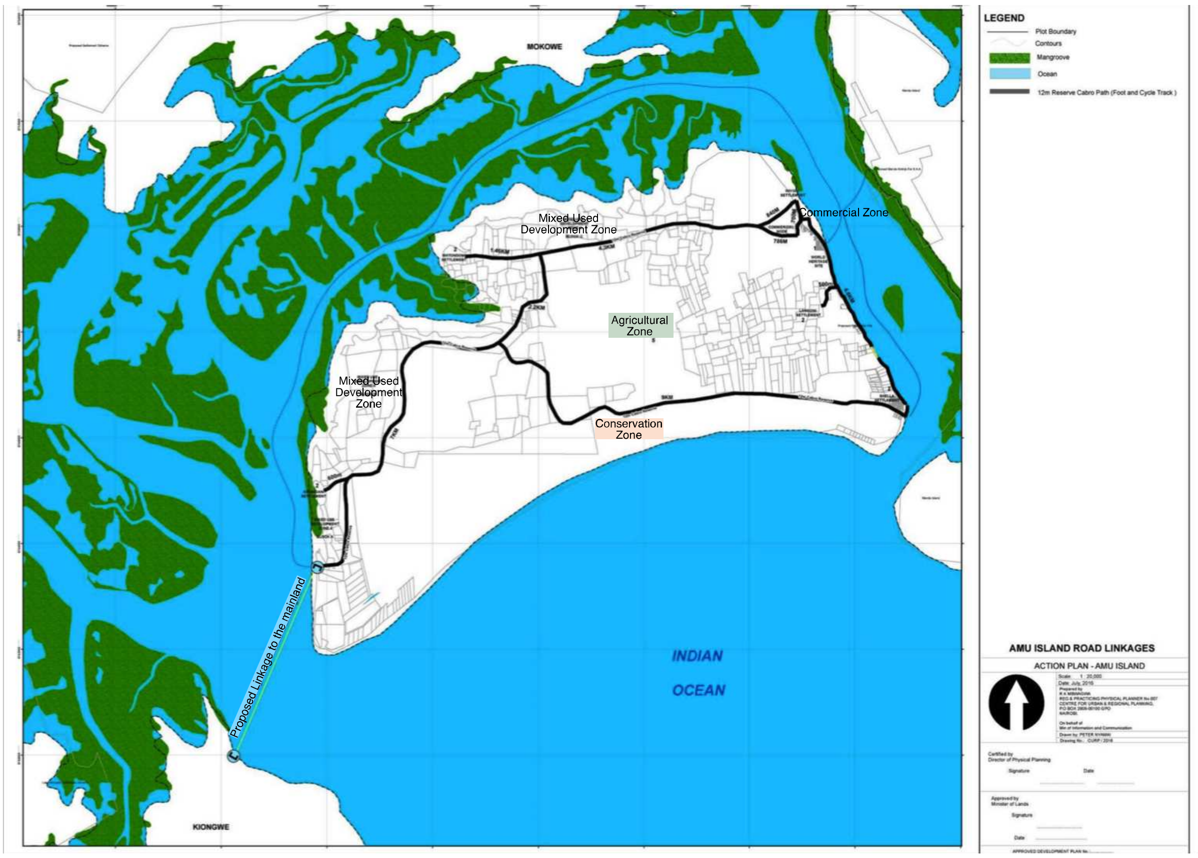

Fig. 9: Proposed Spatial Plan, 2013 (Source: Lamu County Spatial plan)

4.3.2 <u>Impact Assesment Test on The Heritage Site</u>

The National Museum of Kenya (NMK) on behalf of the state-party to the World Heritage Committee (WHC) by conducting a Strategic Environmental Assessment (SEA) which was used as a tool for

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

safeguarding and building sustainable policies, plans and programs and the strategic initiatives of LAPSSET corridor Infrastructure Development Project, that there was a changing in the order of land use (NMK 2017). Lamu's landscapes are seen to undergo drastic changes. Such as; increase in land-use change in favor of settlement and urbanization, communities becoming more sedentary more or so around permanent water sources, increased in the commotion for individual land ownership, constricted livestock grazing leading to overstocking and localised overgrazing, increased adoption of both rain-fed and irrigated agriculture, increased human/wildlife conflicts, increasing land degradation and reduced carrying capacity, pastoral livelihoods under great threat and last but not least, increase of severity and impact of droughts (NMK 2017).

Moreover, on the question of escalating poverty; Lamu's livelihoods are under threat from:reduced carrying capacity, increased severity and impact of cyclic droughts. Increased in unemployment especially for young adults, dwindling water resource base and cases of Lamu dropouts on the increase. Overall poverty levels in Lamu remain high (NMK 2017).

In addition to the pre-existing concerns on community land management, the following was stated: Lamu lands are undergoing drastic and accelerated change due to: intensified clamor for individual ownership of formerly communally owned land, accelerated and contentious allocation of communally owned land, official and unofficial encroachment on community land, lack of appropriate legal mechanism to govern community land and increasing conflict over access and control of land (NMK 2017).

In the Strategic Enivornmental Assessment (SEA) for Lamu County Infrastucture Development Project the following were given as the priority concerns; the question of water demand management,inorder to support urbanization, industrialization, port functions, etc. Modalities for co-existence between LAPSSET investments and wildlife. Wildlife dispersal areas and corridors. Impacts on biodiversity and ecosystem services. Endemic and rare species. Loss of forest cover, mangrove ecosystemwhich also acted as the breeding areas for fish. Potential impacts on land, land ownership and associated benefits. Rush to alienate community land to private individuals and firms. Impacts on pre-existing livelihoods and production systems. Indigenous forest-dependent communities such as pastoral systems andfishermen. Modalities for sustainably managing change; Immigration, cultural dilution, political implications; Urbanization and industrialization –social services. Management of the environmental balance; Environmental flows, waste management and pollution (NMK 2017).

5 DISCUSSION

This section discusses the findings from evidence gathered through the on desk survey, interviews, and photo-survey discussed above. Data analysis has been conducted through questionnares, interviewing officials, and direct observation notes. Photos shown in this section are taken as part of the direct observation and photo-survey of Lamu Old Town. Furthermore, the representation of cultural heritage from the document analysis is included in this data discussion. Two thematic areas of discussion emerged from the findings.They include: effect of uncontrolled development on the heritage site (5.1) and valuing heritage on an intangible dimension (5.2)

5.1 Effect of Uncontrolled Development on the Heritage Site

Through the inadequately planned and managed heritage site Lamufaces immense challenges in its urban context. For instance, as a result of unsafe housing with poor provison for clean water, sanitation, inadequate infrastructure and services that currently Lamu is facing, can turn natural hazard into a disaster. By way of illustration as seen in figure 5a, with an open storm water drainage near the market area which tends to block oftenly due to the unsanitary conditions, could result to an outbreak of harzadious diseases such as cholera.

Lamu Town experiences a drastic change in its physical context from several issues that are as a result of sporadic increase in population. This being a small island with a limited carrying capacity posses a major issue in land efficiency. Through the census that was conducted in 2019, the population surpursed the computed number by twice the estimate. As a result, it caused the encroachment of conserved areas, land conversion by building on agricultural land and land demand sky rocketing as people with purchasing power out buy the locals creating a major threat towards the intangible heritage.

From the traditional mode of transport being donkeys and carts to how buildings interact with one another and with the streets, to how open spaces function as a socialising space gives this town a unique urban heritage that generates tranquility and ambience. However, due to poor management, the town is experiencing a sporadic change, from uncontrolled motorcycles, pollution and servicing as seen in figure 5a, 5b and 8b, 8c.

Despite having a magnitudinal project neighboring the area, the essential aspects such as: water which is rationed by each house-hold getting access to water twice in a week for an hour each, surge in electricity in the evenings, sometimes blackouts and waste management are far from reach. An issue that will continue to worsen as population increases if not handled instantaneously. The issue in proposing a different waste management that includes the sewer system is critical, as negligence in it could cause an epidemic.

Moreover, as the town expands, the denser it becomes and so do the conditions of the environment change. Due to the uncontrolled development and poor spatial planning there are no play areas for children or adequate open spaces which are currently only found at the sea front see figure 7a and 7b. In additon, there are no policies implaced that manage or reduce existing and future disaster risks, which can prove to be catastrophic were there to be an outbreak or a disaster such as fire and other natural causes.

5.2 Valuing Heritage: Intangible Dimension

In its landscape, urban planning plays a significant role in reinforcing a town’s identity through the integration of heritage and historic urban area conservation, management, and planning strategies into local development processes and urban planning aids (Girad L. 2013). An ideology that lacks in the preservation of Lamu’s cultural heritage. Moreover it fails to acknowledge the interconnectedness of economic, social, cultural, and environmental systems that could play as a key resource in urban sustainable development.

Through local expert interviewees, they pointed out that the local politicians are not concerned with the value assigned to Lamu’s cultural heritage as they should and without political buy-in and commitment, heritage is then being left at the margins of urban development.

Furthermore, the developments have affected the major economical activity of Lamu Town, the artisinal fishing industry. Where traditional methods of fishing is still used and their main fishing grounds affected by the port development. Regardless that some fishermen were compensated, it was not a sustainable solution as the money was inadequate and for them not being exposed and learned, their lives becoming difficult. And there is still no measures that have been placed to enable the fishermen to go deep sea fishing

Without the acknowledgment and appreciation of Lamu’s culture and values, opportunities for establishing social cohesion and connectivity are missed. Lamu’s urban fabric is under consistent pressure to “modernize”, leading to the continuous disappearance of traditional skills and crafts that are part of the intangible cultural heritage (Jigyasu R. 2014). Expert interviewees commented on the depreciation of a sense of place and belonging in the commoners of Lamu due to the various physical environmental challenges mentioned above and the increase in population.

In addition, the social connectivity and cohesion are becoming weak and therefore there is lack of interest in engaging with Lamu’s heritage. This challenge will worsen when considering migrant populations who have settled in Lamu primarily for industrial activities and have no inherited sense of responsibility to conserve and value Lamu’s heritage.

6 CONCLUSION

This paper has examined the challenges the commoners face in Lamu’s Heritage Site as a result of poor spatial planning. The discussion is based on the grounds of a growing population in a poorly managed urban setting and how its negligence affects the identity of the commoners. The town of Lamu is explored as an exemplar study through qualitative fieldwork. Although Lamu is yet to make effective steps in addressing its spatial planning issues and the existing challenges on commoners. The findings from this study highlight the following:

The need for decision-makers with the involvment of the commoners to enforce new policies that protects the already diminishing heritage by acknowledging the spatial injustice the commoners face.By providing better living conditions through adequate infrastructure, good management and cooperating both formal and informal sectors.

As a result of the sporadic increase in population in a limited land carrying capacity, the future generation of the commoners is faced by a threat as people with purchasing power outbuy the commoners from their ancestral lands. Inorder to sustainably preserve the heritage of Lamu by valuing the intangible dimension, policies that protects the commoners from being replaced should be considered.

Of great significance should be, that the commoners are able to live in a condusive environment that they could reflect as their identity. Proper spatial planning policiesthat reflect the commoners identity by borrowing from the past should be adopted. Inthat it will allow them to have a sense of belonging.

To maintain its land use allocation pattern of Lamu, there is a need to asses, monitor and oversee the trend and the pattern of development as they happen. For instance the uncontrolled motorized traffic that threatens to destroy the unique ambience of the island. For the unchecked development damages the beauty of Lamu and the sustainability of the heritage site.

Assembly points should be designated as part of the disaster risk management strategy. As it is, Lamu town is densly populated and measures of prevention of disaster is highly significant.

An initiative should be taken in developing an alternate waste management strategy which may include installation of risk-reducing infrastructure such as closed storm water drainage and slope stabilization as the current is not environment friendly and with the increase in population, the situation will worsen.

Future research can be focused on urban cultural representation. Lamu is not a unique case, the narrative on this case study reflects current challenges on conservation of heritage assets in rapidly-growing urban areas and also portrays how much the commoners are affected by such pressures.

1 ABSTRACT

Cities reflect diverse spatial patterns as a result of their composition in population density, building forms, and household types. These differences, to a large extent, reflect the quality of life of an area's inhabitants and the correspondent environmental load their lifestyles impose. Environmental load is related to the supply and demand for food, energy and water. As a result, identifying gaps between supply and demand is a common starting point for urban planning and design aimed at zero-carbon emissions and other forms of sustainable urbanism. In this regard there is substantial research and tools that can be applied to these issues. One typical example is the Ecological Footprint which uses an equivalent land area to express the demand for the production of goods and CO2 absorption. This indicator is powerful at the macro level with regards to the conceptualization of the problem, but difficult to use at the small scale when considering the benefits of particular design options. Against this background, this study aims to develops an indicator to express a design baseline that enables the quantitative evaluation and comparison of the demand and supply of FEW as well as their contribution to environmental load with regards to food, energy, and water at the city block level.

Many environmental indicators were developed in recent years to clarify the interaction of the so-called FEW Nexus, or the confluence between the otherwise separate realms of food, energy, and water. However, these indicators are also difficult to apply at a small scale. This study develops an index that enables the quantitative evaluation and comparison of the relationship between food, energy and water at the city block level. The demand and consumption for food, energy, and water associated with residences are strongly influenced by the type of households under consideration. Meanwhile, the potential production and supply of food, energy, and water for a given household is mostly determined by the capacity to install solar panels and home gardens, which are themselves strongly determined by building forms and land use. Therefore, the baseline of a city block for FEW demand and supply can be assessed by identifying the type of households and the form of buildings within it. With this in mind, we categorized "household types" in terms of the number of family members, the age group and gender; "building form" is defined either as a detached house or an apartment. The demand for food, energy, and water associated with a given "household type" (per household or per capita) is defined as social intensity. The unit associated with "building form" is defined as physical intensity. The social and physical intensity were carefully identified through statistical data and previous studies. Based on these preparations, the demand for FEW, as well as the amount of production, can be estimated at a household level and aggregated to the city block level. Physical estimation of the demand and supply are then converted to an environmental footprint by applying the concept of the Ecological Footprint to FEW.

This indicator was applied to the Tokyo-Yokohama metropolitan area as a case study. In order to improve the comparability at the regional level, the metropolitan area was categorized by three forms, namely the inner city, near urban and suburban. Typical areas were selected to represent the social and spatial characteristics of each. Finally, the method was applied at the metropolitan scale using GIS data in sample areas.

The result clearly shows the spatial differences in demand and supply of food-water-energy as well as the correspondent environmental print. While the environmental print per unit area is greater in the inner city, the per capita number is greater in suburban areas. This indicates that suburban areas have a larger responsibility to reduce their environmental footprint through food-water-energy consumption. This knowledge is helpful to move environmental issues from being a matter of concern for the government to being a problem for communities and individuals.

Keywords: Ecological footprint, GIS, Building form, Environmental load, Food-Water-Energy Nexus

2 BACKGROUND

While food, energy, and water (FEW) play a central role in the system that supports the demands of human life, the CO_2 emitted in the process reaches nearly 70% of the global CO_2 emissions (Ramaswami et al., 2016). In addition, the majority of the world's population was officially urban from 2007, and the number is only increasing. By 2050 two-thirds of the world's population is expected to live in urban areas, and FEW consumption is subsequently concentrating in urban area(Kammen & Sunter, 2016). As a result, urban areas face increased sustainability challenges and are faced with the need to pursue ever higher resource efficiencies. However, the demand and supply of FEW have traditionally been managed separately in each sector, and efforts to reduce carbon outputs are reaching their limits. Therefore, in recent years, attention has been focused on the complex demand and supply networks that exist between FEW sectors, and resource efficiency is expected to be improved using these interactions.

It is known that there are large local differences in FEW consumption in cities, and that the potential of the FEW nexus is regionally dependent(Jones & Kammen, 2011). This is connected to the fact that 50% of a city's CO_2 emissions are attributed to its urban structure, including population density, land use, and building types(Christen et al., 2011). Given the extraordinary diversity of urban systems (climate, geography, morphology, demographics, culture, and economy), effective CO_2 emission reductions are necessarily context dependent(Kellett et al., 2013). Without that simple understanding, cities cannot make decisions on how and where to direct the application of policies and regulatory measures. However, with regard to the FEW nexus at the city level, previous efforts by researchers have concentrated on quantifying the flow of the FEW nexus, with little assessment of qualitative factors such as the geographic, historical, and political context of the cities that house them(Newell et al., 2019). Cities are beginning to implement the FEW nexus, and accumulating qualitative knowledge in implementing the nexus approach is an urgent (Artioli et al., 2017; Simpson & Jewitt, 2019).

Against this backdrop, the design-led implementation of the FEW Nexus is gaining attention as an interdisciplinary design-led approach.(Yan & Roggema, 2019). Such a design-led approach is characterized by its ability to comprehensively handle complex systems, such as supply chains or those involving multiple stakeholders(Fleischmann, 2019). This shows how a design-led approach is suitable for dealing with the complex supply and demand that exists between the various sectors of the FEW, but the tools to support this approach are not yet well developed. For example, there is no FEW Nexus indicator designed to accommodate the multi-scale approach often seen in urban design.

In order to develop an indicator tool to support a design-led approach, this study visualized the relationship between FEWs at the urban, neighborhood, and city scales, and developed an environmental load indicator that can be used as a design baseline for the FEW Nexus. This environmental load is limited to that associated with FEW demand, and in this study, it is limited to carbon dioxide (CO_2) emissions, the largest GHG. We applied this indicator to a case study of the Tokyo metropolitan area to verify the validity and operability of the indicator.

3 CONCEPT OF FEWPRINT

Although many indicators have been developed to assess the environmental impacts of people's daily activities, there is still little consensus on how to apply them(Ramaswami et al., 2021), and the same is true for FEW-related indicators(Newell et al., 2019). However, in the context of linking urban design and environmental impact indicators, the Ecological footprint has gained some recognition(Moos et al., 2006). The Ecological footprint can be converted into a unified unit of area even for different sectors, is convenient for visualization, and is easy to set as a Key Performance Indicator(Moos et al., 2006). The greatest advantage is that there is a common language of "area" between Ecological Footprint and urban design. In general, the space that can be reserved for local production or management of FEW in a dense urban environment is very limited, and clarifying this area is an important first step in urban design. The Ecological Footprint, on the other hand, is calculated as the sum of the land area required to produce and manage various services and the forest area required to absorb the CO_2 emissions generated through the production, transportation, and consumption of these services. In other words, it makes it possible to integrate land use and environmental impact into one study.

On the other hand, there are some challenges in calculating the Ecological Footprint, such as the need to collect data from various sources and the difficulty in applying the method at relatively micro scales due to the problem of data sources(Moos et al., 2006). The main reason for this issue is that most previous ecological footprint studies have focused on entire cities and used a top-down approach of spatially disaggregating energy consumption(Kellett et al., 2013). This top-down approach not only poses the challenge that it is not suitable for application at micro scales, but also that it does not require an understanding of the processes that lead to CO2 emissions and is therefore not suitable for design-driven approaches or scenario-based predictions(Kellett et al., 2013). To address this challenge, recent research has presented an extension of bottom-up models based on consumption processes to enable environmental impact assessment at the micro-scale(Christen et al., 2011; Kellett et al., 2013). This approach not only facilitates the calculation of design baselines at the neighborhood or city block scale, but also facilitates the assessment of the environmental impact reduction potential of new urban forms as indicated by design scenarios. However, this concept has not yet been introduced into the Ecological Footprint.

In this study, the FEWprint will be developed as a subset of the Ecological Footprint, a general indicator that evaluates the impact of human life on nature in terms of equivalent land area, and will be maintained as a support tool for urban design in order to develop the FEW Nexus. As with the Ecological Footprint, the FEWprint is calculated as the sum of the land area required to produce and manage FEW services and the forest area required to absorb the corresponding CO2 emissions through the production, transport, and consumption of FEW services. To estimate the corresponding CO2 emissions through production, transport and consumption of FEW services, a bottom-up approach using social and physical intensities is adopted. Social intensities consist of any group of individuals, households, or age groups, while physical intensities are defined as single-family homes, apartment units, buildings, neighborhoods, or cities. Thus, FEW demand can be assessed at the household or building scale, and further extended to the neighborhood, city, or regional scale. The current FEW demand is used as a baseline from which to begin the FEWprint analysis.

4 METHOD

4.1 Typological analysis

Cities develop diverse spatial patterns as a result of their composition in population density, building forms, and household types. In order to closely represent the impact of these spatial differences on the demand and supply of food, energy, and water, two typologies need to be considered. Firstly, the demand and consumption for food, energy, and water associated with residential life is strongly influenced by the type of households. Secondly, the potential of production and supply of food, energy, and water for a household to alleviate the demand is mostly determined by the capability to install solar panels and home gardens, which is in turn strongly determined by building forms. Therefore, the baseline of a city block for FEW demand and supply can be assessed by identifying the type of households and the form of buildings. We categorized the "household type" in terms of the number of family members, and the groupings of age and gender, and the "building form" in terms of detached houses and apartments. The basis for this classification depends on the available FEW consumption intensity data.

4.2 Baseline calculation

4.2.1 Amount of demand and supply

Food Demand

Regarding food, its demand is largely dependent on age and sex. In other words, the demand for foodstuff (k) in the target area (FD_k) can be calculated by multiplying the food demand intensity by age and sex ($FD_{k,\ age,\ sex}$) by the population by age and sex ($P_{age,\ sex}$), as shown in Equation 1.

$$FD_k = FD_{k,age,sex} \times P_{k,age,sex}$$

In urban areas, the decline in labor force due to the aging of agricultural workers has led to the conversion of ordinary farmlands into allotment gardens. Home vegetable gardens are also gaining popularity because they can be easily managed at home. While it is important to understand the actual situation of such small-scale vegetable production, it is difficult to identify the products in home and allotment gardens without careful fieldwork. However, when estimating for a large area, the work becomes an unmanageable amount.

Therefore, by using the cultivated area of home vegetable gardens by building type (SKGbldg) and the rate of home vegetable garden implementation by building type (RKGbldg), we can simply obtain the production area.

$$L_{FP,farm} = \sum_{bldg} SKG_{bldg} \cdot RKG_{bldg}$$

Energy Demand

In terms of energy, the demand depends largely on the household size. In other words, the energy demand (ED) of the target area can be calculated by multiplying the energy demand intensity ($ED_{household}$) by the number of households per household size ($H_{household}$), as shown in Equation 3.

$$ED = ED_{household} \times H_{household}$$

On the other hand, it is necessary to consider the existence of existing autonomous decentralized energy supply systems. Solar panels are a decentralized power generation system possible at the household level. The amount of electricity generated by solar panels can be estimated from the size and number of panels. The annual electricity production (EP) from solar panels in the target area can be expressed as Equation 4 using the system capacity intensity of solar panels by building type (P_{bldg}) and the solar panel installation rate by building type (RPV_{bldg}). (H), (P), and (K) refer to the average solar radiation, the system capacity of the solar panels, and the loss factor, respectively.

$$EP = H \cdot K \cdot 365 \cdot \sum_{bldg} P_{bldg} \cdot RPV_{bldg}$$

Therefore, the exact energy demand (ED) needs to be expressed as in Equation 5, taking into account the amount of electricity generated by solar panels (EP).

$$ED = ED_{household} \times H_{household} - EP$$

Water Demand

In the water sector, the demand depends largely on the number of household members. In other words, the water demand (WD) in the target area can be calculated by multiplying the water demand intensity ($WD_{household}$) by the number of households per household size ($H_{household}$), as shown in Equation 6.

$$WD = WD_{household} \times H_{household}$$

On the other hand, the construction of a water supply environment in residential areas is being promoted with the installation of water tanks. This is a system in which the rain that falls on the roof is channeled into a water tank to store rainwater. In other words, if we can determine the area of the roof of a house where a water tank is installed, we can calculate the annual water supply by multiplying it by the annual rainfall. The amount of water available for self-sufficiency (WP) of the target area can be expressed as Equation 7, using the positive radiant area of the roof of each building (RA_x), the water storage tank installation rate by building type (RWS_{bldg}), and the annual precipitation (RW).

$$WP = RW \cdot \sum_{bldg} \sum_{x} RWS_{bldg} \cdot RA_x$$

Therefore, the exact water demand (WD) needs to be expressed as in Equation 8, taking into account the amount of water available for self-sufficiency (WP).

$$WD = WD_{household} \times H_{household} - WP$$

Conversion to footprint

Food Demand

Food is linked to energy, water, and land in the process of its supply. For example, land is indispensable during food production. Therefore, the land ($L_{k,farm}$) needed to meet the demand (FD_k) for foodstuff (k) in the target area can be expressed as in Equation 9 using the land ($L_{k,base}$) needed to produce 1 kg of foodstuff (k).

$$L_{k,farm} = L_{k,base} \times FD_k$$

In other words, the total land for the production of food demand (FD) in the target area ($L_{FD,farm}$) is shown in Equation 10.

$$L_{FD,farm} = \sum_k L_{k,farm}$$

Next, we evaluate the energy associated with the supply of foodstuff (k). The CO_2 emissions (CE_k) associated with meeting the demand (FD_k) for foodstuff (k) in the target area can be expressed as in Equation 11 using the CO_2 emission factor ($CE_{k,base}$) of foodstuff (k).

$$CE_k = CE_{k,base} \times FD_k$$

Furthermore, this CO_2 emission amount (CE_k) can be converted into land by replacing it with the forest area required to absorb that CO_2 emission amount. In other words, the forest area ($L_{k,CO2}$) for absorption of CO2 emissions associated with the demand (FD_k) for foodstuff (k) in the target area can be expressed as shown in Equation 12 using the forest area ($L_{CO2,base}$) required to absorb 1 kg of CO_2.

$$L_{k,CO2} = \frac{CE_k}{L_{CO2,base}}$$

In other words, the total land area ($L_{FD,CO2}$) required to absorb CO_2 emissions associated with food demand (FD) in the target area can be expressed as in Equation 13.

$$L_{FD,CO2} = \sum_k L_{k,CO2}$$

And the water associated with the supply of food (k) is usually referred to as virtual water. This virtual water (VW_k) associated with food demand (FD) in the target area can be converted into land area by replacing it with the area required to absorb equivalent water as rainwater. Introducing this idea, the area ($L_{k,VW}$) required to acquire the virtual water (VW_k) associated with the demand (FD_k) for foodstuff (k)in the target area from rainwater can be expressed as in Equation 14 using the annual rainfall (RW) in the target area.

$$L_{k,VW} = \frac{VW_k}{RW}$$

In other words, the area ($L_{FD,rain}$) required to obtain the virtual water associated with the food demand (FD) of the target area from rainwater can be expressed as in Equation 15.

$$L_{FD,rain} = \sum_k L_{k,VW}$$

Energy Demand

Energy is supplied from a variety of energy sources, and each energy source generates different CO_2 emissions. In other words, the CO_2 emissions (CE_{ED}) associated with the energy demand (ED) in the target area can be expressed as in Equation 16 using the sharing ratio (ERR_l) of a certain energy source and its CO_2 emission coefficient ($CE_{l,base}$).

$$CE_{ED} = ED \sum_l (ERR_l \cdot CE_{l,base})$$

This CO2 emission (CE_{ED}) can be converted to land by replacing it with the forest area required to absorb the CO2 emission. In other words, the forest area ($L_{ED,CO2}$) required to absorb CO2 emissions associated with energy demand (ED) in the target area can be expressed as in Equation 17 using the forest area ($L_{CO2,base}$) required to absorb 1 kg of CO_2.

$$L_{ED,CO2} = \frac{CE_{ED}}{L_{CO2,base}}$$

By the way, hydroelectric power generation is one of the energy sources. The area ($L_{ED,rain}$) required to obtain the amount of water ($W_{ED,hydro}$) used in hydropower generation from rainwater can be expressed as in Equation 18 using the annual precipitation (RW) of the target area.

$$L_{ED,rain} = \frac{W_{ED,Hydro}}{RW}$$

Water Demand

A lot of energy is required for water supply. This energy is supplied from various energy sources, and each energy source has different CO_2 emissions. In other words, the amount of CO_2 emissions (CE_{WD}) associated with the water demand (WD) in the target area can be expressed as Equation 19 using the amount (ER_m) shared by a certain energy source (m) in water supply and its CO_2 emission coefficient ($CE_{m,base}$).

$$CE_{WD} = \sum_m (ER_m \cdot CE_{m,base})$$

This CO_2 emission (CE_{WD}) can be converted to land by replacing it with the forest area required to absorb the CO_2 emission. In other words, the forest area ($L_{WD,CO2}$) required to absorb CO_2 emissions associated with water demand (WD) in the target area can be expressed as in Equation 20 using the forest area ($L_{CO2,base}$) required to absorb 1 kg of CO_2.

$$L_{WD,CO2} = \frac{CE_{WD}}{L_{CO2,base}}$$

The area required to obtain the water demand (WD) from rainwater ($L_{WD,rain}$) in the target area can be expressed as Equation 16 using the annual rainfall (RW) in the target area.

$$L_{WD,rain} = \frac{WD}{RW}$$

Environmental loads of FEW demands

The total environmental impact in terms of land, is calculated in 4.2.2. However, it should be noted that the water used for hydropower generation is subsequently used for domestic and agricultural purposes. To reflect this, the environmental impact (EI) can be expressed by the following equations.

When $L_{ED,rain} \geq L_{FD,rain} + L_{WD,rain}$

$$EI = L_{FD,farm} + \sum_n L_{n,CO2} + L_{ED,rain}$$

When $L_{ED,rain} < L_{FD,rain} + L_{WD,rain}$

$$EI = L_{FD,farm} + \sum_n L_{n,CO2} + L_{FD,rain} + L_{WD,rain}$$

$$(n = FD, ED, WD)$$

5 CASE STUDY

5.1 Features of study area

The target areas are Tokyo prefecture and Kanagawa Prefecture, the latter being located in the southwest part of the Tokyo metropolitan area, which has the world's largest population. In these two prefectures, more than 23 million people live in an area of about 4,600 square kilometers. Many of the urbanized, built-up areas were developed during the high economic growth period after WW II and widely spread in suburban and extra-urban along radially distributed railways. Similar with all of Japanese cities, this region is facing declining birthrates and an aging population. Therefore, the governmens are trying to remake the cities in a more compact form by attracting services and residents to the walkable area near railway stations. In addition to, the built-up areas are approaching a time when infrastructure and other upgrades will be needed, as the vulnerability witnessed by the devastating disasters like the Great East Japan Earthquake in 2011, the heat wave in 2018, and the super typhoon Hagibis in 2019. Adding to that existential fear is a political and moral issue. In consideration of its size, the metropolis has a responsibility to act urgently to reduce CO2 production. It is similarly useful to recognize that the production and consumption of food-energy-water is responsible for more than 60 percent of total CO2 emissions. In responce the Japanese government initiated an action plan on climate change adaptation in 2015. It also lunched the SDGs Future City Program in 2018 to accelerate the transition and transformation towards a carbon neutral and sustainable society.

5.2 Data management

The respective data on age and number of households by household size required to determine the social typology was obtained from the 2015 census. Other data required in the process of analysis were maintained as shown in Table 1.

Variable	Description	Data Source
$CE_{k,base}$	CO2 emission coefficient of food (k)	Ministerial Order Concerning Calculation of Greenhouse Gas Emissions from Business Activities of Specific Emitters (2016)
$CE_{l,base}$	CO2 emission coefficient of energy source (l)	
$CE_{m,base}$	CO2 emission coefficient of energy source (m) required for water supply	
$ED_{household}$	Energy demand intensity by household size	(Inoue et al., 2006)
ER_m	Share of energy sources (m) in water supply	Energy Consumption Statistics by Prefecture (2017)
ERR_l	Share of energy source (l)	
$FD_{k, age, sex}$	Food demand intensity by gender by age	National Health and Nutrition Survey (2019)
$H_{household}$	Number of households by household size	National Censes (2015)
$L_{CO2,base}$	Forest area required to absorb 1 kg of CO2	Forestry Agency
$L_{k,base}$	Land required to produce 1 kg of food (k)	(Yan & Nakayama, 2021)
$P_{age, sex}$	Population by age and sex	National Censes (2015)
RW	Annual precipitation	Japan Meteorological Agency
VW_k	Virtual water for food (k)	(Oki & Kanae, 2004)
$WD_{household}$	Water demand intensity by household size	Bureau of Waterworks Tokyo Metropolitan Government

Table 1: “List of sources of data needed for calculating FEWprint”

5.3 Result

Using the methods in Chapter 4 and the data collected in 5.2, we visualized the FEWprint in GIS in Figure 1 and Figure 2. Figure 1 shows how many times the FEWprint is the area of the city by the census truck. In Figure 2, we visualize the value of FEWprint per capita. The result clearly shows the spatial differences in demand and supply of food-water-energy as well as the correspondent environmental footprint. While the environmental footprint per unit area is greater in the inner city, the amount per capita is greater in suburban areas. This indicates that suburban areas bear a larger responsibility to reduce their environmental load through food-water-energy consumption.

6 DISCUSSION

A study that analyzed CO2 emissions in Chicago showed similar results to our analysis, with per capita CO2 emissions being higher in the suburbs(Farr, 2007). However, compared to Figure 1, the difference between urban centers and suburban areas in Figure 2 is not as clear. This is a feature that was not seen in the previous report(Farr, 2007). This suggests the characteristics and issues of the FEWprint presented here. In this calculation of the FEWprint, we considered differences in demand due to household size and age, and supply capacity due to building structure, but there were no variables that directly represented differences between urban centers and suburbs, such as building size. Furthermore, we did not take into account the mobility associated with food procurement, which is expected to be very different between urban centers and suburbs. However, it has been pointed out that the environmental burden associated with food access is significant(Coveney & O’Dwyer, 2009). In order to bring environmental issues down to the level of the general public and to make concrete designs, the urban structure needs to be reflected in more detail in the FEWprint.

The key point of the design-led approach for FEW Nexus is the use of area. How much productive area already exists, how much is potentially available, and how much can be created through design. The potential of an area can be calculated with the use of the FEWprint tool in an iterative manner, a familiar process for those who work professionally in any design field. This means that each time a design is considered and re-evaluated in the normal design process, it can also be modified and evolved depending on how much productive area can be developed. In this way, the FEWprint serves as a baseline for design.

The FEWprint is useful not only for evaluating the baseline of FEW demand, but also for evaluating efforts to reduce CO2 emissions in the process. Implementing the FEW Nexus as a policy or policy vision also requires assessments and approaches at different spatial levels, such as buildings, city blocks, neighborhoods,

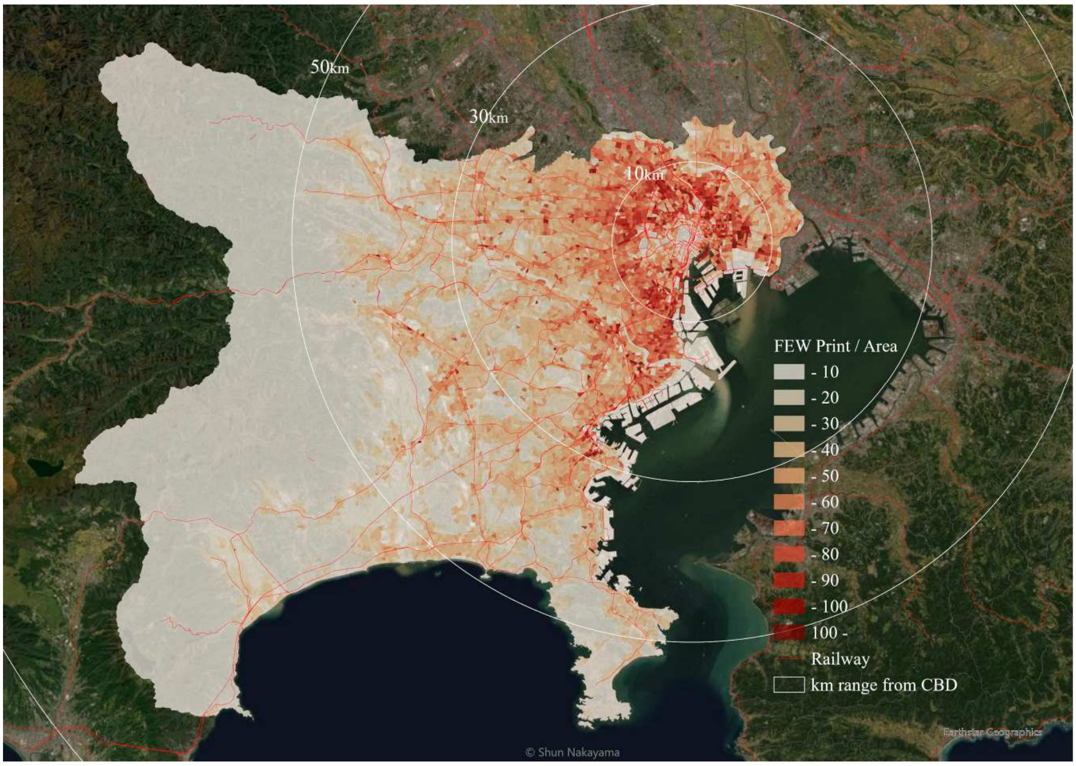

Fig. 1: How many times the FEWprint is the area of the city by the census truck.

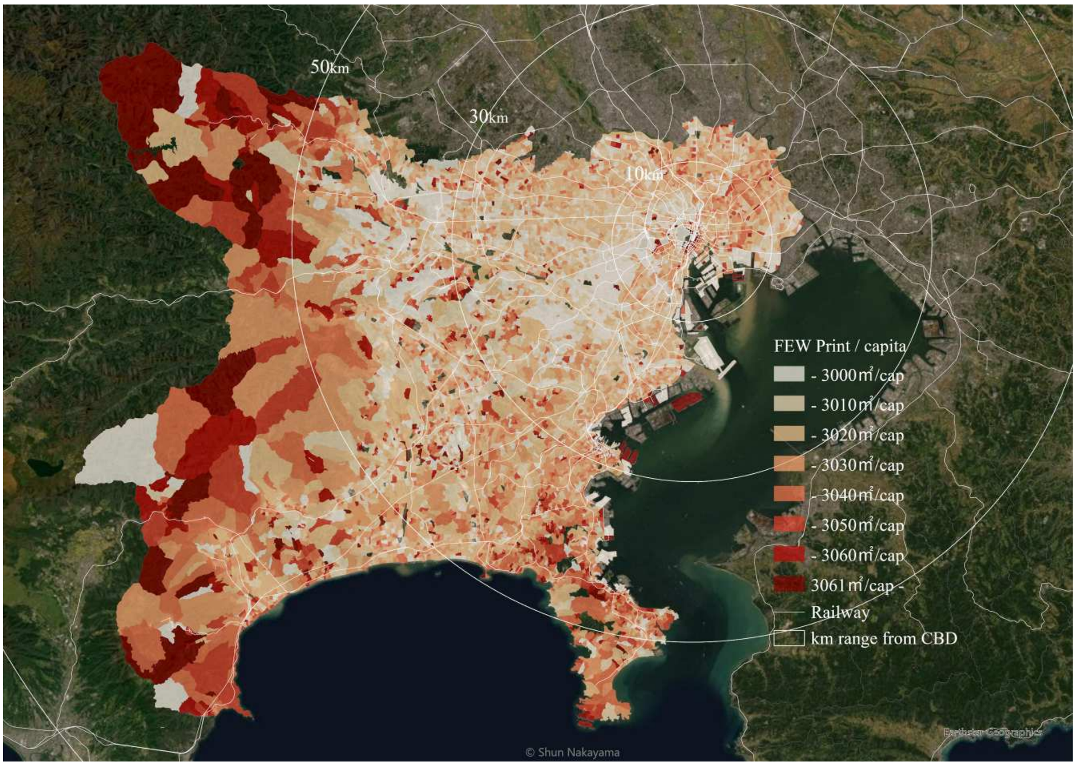

Fig. 2: The value of FEWprint per capita

and cities. This can be done by applying the FEWprint to future scenarios. If this results in a reduction of FEWprint, it means a more efficient use of FEW resources. GIS is a suitable way to represent FEWprints at multiple scales.

7 CONCLUSION

In this study, we noted that the essence of the design-led approach for FEW Nexus is the area available to meet the demand-supply for FEW physically and the area required to absorb the environmental costs both in the present and the future. These two apects are evaluated quantitatively by introducing the FEWprint as a key performance indicator.

Armed with this instrument, we could quickly evaluate the FEW baseline in any specific conditions by identifying a set of dietary tables, household and building types. This baseline can be used as reference to examine the performance of new designs, the nexus effects that will be achieved by specific solutions, the performance of a stakeholder, or the effect of relevant urban policy. By giving the available area in a house, a building, a block or a neighborhood as well as the social and physical intensity for food, energy, water, the M-NEX method is applicable to any scale with the support of GIS.

8 ACKNOWLEDGEMENT

M-NEX is a granted project of Collaborative Research Area Belmont Forum (no. 11314551) led by Wanglin Yan (Keio University) in consortium with partners from Japan, including Keio University and Institute for Global Environmental Strategies, Qatar, led by Kas Oosterhuis at Qatar University, the USA, led by Geoffrey Thün at the University of Michigan, the Netherlands, led by Andy van den Dobbelsteen at Delft University of Technology, the United Kingdom, led by Greg Keeffe at Queens University Belfast, and Australia (collaborator, led by Rob Roggema). Local governments, companies and communities are involved in the activities of the national teams. We are grateful to JPI Europe Urban for initiating the “Sustainable Urbanization Global Initiative—Food-Water-Energy Nexus” and making the M-NEX project possible.

(Professor Takayuki Ito, Kyoto University, Kyoto Japan, ito@i.kyoto-u.ac.jp)

1 ABSTRACT

While the use of incentive mechanismsto stimulate efficient communication and collaboration among individuals in online platforms, groups and communities has been widely documented and discussed, comparatively little is known about the influence of age and gender on the motives for participation in these platforms and how responses may vary based on these personal attributes in less developed countries like Afghanistan. In this paper, we examined if the age and gender of the respondents affect the kinds of incentivesthat stimulatetheir effective participation in online discussions andifsuch online discussions have a social influence on participantspresented with such incentives. To this end, we firstrun an idea contest project, using a real word online discussion forumcalled D-Agree in collaboration with Kabul Municipality (KM). Weincorporateddifferent incentive schemes which yielded 3,892 respondents/participants whocumulatively exchanged14,587 opinions and responses on the platform. This enabled us to conduct a post discussion survey, usingSurveyMonkey where 201 respondents participated. We demonstrate that financial (e.g. monetary reward) and social (e.g. fulfilling the desire to learn and improve one's abilities, knowledge and experience)motives consistently outperform all other incentivesas motivators of participation in Afghanistan. The results of this work demonstrate that males and females are influenced by similar incentives to participate in online discussions. As for the social influence of participating in online discussions, the results show that respondents were affected from a moderate level to a great deal, butwith no significant differences based on age and gender. The output of this research might open a new direction in the study of social influence based on incentive mechanisms. This could be used as a planning tool to stimulate participation in forums/platforms for crowdsourcing.

2 INTRODUCTION

The emergence of computer mediated communications over the past few decades has dramatically changed many people's social lives (Sun et al. 2011). In particular, online forums have become a major medium for facilitating large-scale discussions on various issues ranging from personal, family, societal to governance. Online communities, which are usually divided into smaller groups within these forums, might act collectively in ways that seem intelligent (Malone et al. 2009). Thus, online forumshave attracted research attention as an approach to discourse-centric collective intelligence to offer innovative solutions for improving critical social problems (Haqbeen et al. 2021). Online forums provide efficient tools for eliciting participation in crowdsourcing projects and policy-making. While some discussions in online forums may be very specific(e.g. discussions of climate change issues in Climate CoLab platform or urban-related SDGs in D-Agree platform), some othersmay be general social platforms with unrestricted focus (e.g. discussing travelexperiences in TripAdvisor or sharing social experiences about one's self, family, career or pressing social problems such as insecurity, public health issue like the global CoronaVirus pandemic, unemployment and inequality on Facebook). Unlike the discussions in conventional forums where people just share their experiences and communicate with one anotherthrough citizen-initiative interactivities,participants in specific purpose discussion forums focus on solving particular thematic social problem, such as climate change (Introne et al. 2011; Klein 2007), challenges of urban planning and enforcement(Haqbeen et al. 2020a; Haqbeen et al. 2020b) orthe CoronaVirus pandemic (COVID-19)(Haqbeen et al. 2020c; Haqbeen et al. 2020d). These forums foster democratic deliberations aimed at generating innovative solutions to improve the society in line with the United Nations' sustainable development goals (SDGs)by focusing on solving specific social problems.

Users in online discussion forums may be autonomous individuals, but they often participate in discussions as collectives. The insights and intelligence from these collectives cannot be explained by aggregation of individual intelligence(Woolley et al. 2010) and being part of these collectives seems intelligent (Malone et al. 2009).However, in online forums, the level of interactivitymay be low due to the distributed and asynchronous nature of online discussions[Tavanapour et al. 2019]. As a result, peoplemay not actively take part in discussions as collectives. Therefore, in order to encourage people to actively discuss in an online environment, incentive mechanismssuch as discussion gamification (Dai et al. 2016), virtual incentive(Takahashi et al. 2016), scoring systems and automated facilitationhave been developed (Ito et al. 2020).

In view of the foregoing, different type of artificial intelligent (AI)-enabled facilitation such as argumentative facilitation (Hadfi et al. 2021); discussion visualisation and incentive mechanisms (ranking system, gamification) have been introduced as extrinsic motivation solutions for online discussions with a view to stimulating interactivity and boosting users' intrinsic motivation. Specifically, AI-enabled facilitators and discussion scoring systems can spur interest in the discussions and help individuals to interact with one another.The online discussions which utilizesa scoring system is proposed to enhance the various intrinsic and extrinsic motivational factors that are directly proportional to participants'engagement(Ito et al. 2014; Takahashi et al. 2016). Gamification, which includes point-based systems and virtual rewards, acts as a strategy toincrease the contributions of members involved in online communitiesand discussions (Takahashi et al. 2016).

Studies show that both intrinsic and extrinsic motives affect individuals' decision to participate in these online platforms and communities and their level of interactivity with other individuals. In online discussion forums, users are motivated to take part in discussions when observing other users' participation (Sun et al. 2011). This influence may be strengthened by incentive mechanisms such as gamification, ranking system facilitation or other factors. However, little is known about what types of extrinsic incentivesinfluencepeople to participate in online asynchronous discussions in lessdeveloped countries like Afghanistan and if the effect of these motivators is dependent on the ages and gender of participants. Therefore, this study contributes towards filling this knowledge gap by highlighting the factors that facilitate the collaboration and interactivity of individuals in online environments.In this paper, we explored how extrinsic motivators influence participation and level of interactivity in online discussions and if these motivators differ for different ages and genderof respondents.The findings of this study may be useful for the providers of crowd discussion support platforms and "crowd-sourcers" in selecting appropriate incentives for crowdsourcing in Afghanistan and elsewhere.

2.1 Problem statement

A fundamental concern when implementing crowdsourcing is how to meaningfully engage participants. Crowdsourcing involves engaging anonline community or multiple communitiesthrough online forums in order to harness the knowledge of citizens into the process of policy-makingby an interested party, individual or organization (Brabham 2008).However,crowdsourcing initiatives may be marred by lack of interest, asynchronous discussions, and low participation rate if adequate or best-fit incentives are not incorporated. Therefore, crowdsourcers must not only introduce extrinsic motivators in their crowdsourcing initiatives, but also, such incentives must resonate with the personal and social attributes of targetsin order to increase their chances of participating in discussion forums and policy dialogues. In reality, however, identifying the right mix of incentives that could spur participation in online discussion forums remains a daunting challenge.

On the other hand, not much attention has beenpaid to the social influence of active participation in online discussions on people and if the social influence of such participation variesbased on the ages and gender of participants. Social influencerefers to the process through which people change their minds, modify their views, or change their behaviour as a result of their social interactions with others(Moussaïd et al. 2013). Thus, there is a need to identify various motivational beliefs, as well as gender and age-related behavioural attitudes toward online discussions.

2.2 Motivation and incentives

Motivation arises through interaction among different motives and incentives in a particular situation (Atkinson 1958). Motivation is mainly classified into two: intrinsic and extrinsic (Hossain 2012a). Intrinsic motivation refers to the motivation that isdriven by the tasks, so that individuals do not require external pressure(extrinsic motivation) to activate it. According to Lepper et al. (1973)people are intrinsically motivated if the task itself is enough for satisfaction and there is no further reward apart from the activity.

However, extrinsic motivation is driven by external incentives. Factors such as curiosity or interest are examples of intrinsic motivators while extrinsic motivators could be financial, social and organisational. Low motivational levels presented by participants in discussions degrade the discourse's collective intelligence and result in a lack of interest to collaborate with one another.When the motives differfrom the actual activity, external factors such as money, fame, prize etc. prompt motivation (Hossain 2012b).

In online discussions, both intrinsic and extrinsic motivators areneeded to influence participants' engagement (Haqbeen et al. 2021).Sincemotivation is considered a process to release, control, and maintain discussion activities,it is imperative to know the factors that motivate people to participate. Having insights about different incentives helps to boost the motivationof participants to engage in and contribute meaningfully to online discussions, even though participation in such discussions mayimpose some constraints on their time and other resources.

To do this, we adoptedthe concept of discussion scoring and ranking system as virtual gamification and linked it with financial and social rewards in the online discussions. D-Agree ranksthe participants based on their virtual points which are in turn assessed through postings, replies, and likes, or received likes and replies from other participants. We proposeda monetary reward of 30k, 20k and 15k Afs (≈ 385, 257 and 192 USD) for top three and certificates to top ten participants, respectively at the end of the contest project.The cash prizes and certificates to the top threeand ten discussants, respectively (female = 1 and male = 9) were given by the Mayor of Kabul City at an official ceremony (see link to the award ceremony at https://www.youtube.com/watch?v=xdhZYJo_8nQ.

3 METHODOLOGY

We used an onlinediscussion forum based on facilitation. This was followed by an online survey, which sought information from respondents on what motivated themto participate inonline discussions in order to assess the effects of the proposed incentiveson their participation. We focused only on respondents'datagenerated from survey forum in this study.

3.1 Study area

The current study used an open call idea (Brabham 2008) to shed light on motivation factors in online communities in Afghanistan. The open online call was chosen due to itsaccessibility given the representation of Afghan citizens in online communities both in Afghanistan and other parts of the world. Respondentswere asked to join specific discussion spaces based on their residential areas and preferred time.We created 24 virtual spaces, 22 for Kabul city, comprising 22 urban districts, 1 for the 34 provinces of Afghanistan and one for Afghans in the diaspora.

3.2 Sample and sampling method

We used D-Agree as the discussion forum and SurveyMonkey as our survey instrument for this study.First, we used D-Agree, a text-based online discussion platform,which is anchored on support and facilitation means like artificial facilitation, incentive mechanism, ranking system and content visualisation developed by our team for hosting large-scale discussions or deliberations (Ito et al. 2020). The users in online communities were asked to join specific discussion spaces based on their residential areas and preferred time. The call for participation was made using open idea call techniques of convenience sampling.The call to participate was posted on Kabul Municipality's Facebook Page. KM's official Facebook page has 382,000 followers as of July 6, 2021. Thus, the link was available worldwide and could beviewed by anybody with an internet connection. The online discussion social experimenttook place from August 13 to October 02, 2020 and generated 14,587 opinions from 3,892 registered participants.

Following the online discussions, using D-Agree, we used SurveyMonkey as a post-discussion survey instrument to assess if the incentives introduced within the online discussions had any effect on their interest to engage in the discussion activities as well as their opinions and behaviourin the course of the discussion and after. SurveyMonkeyis a cloud-based software used by researchers to collect data on various issues of interest to them. Itspecialises in online surveysand rapid productionof results (Halim et al. 2018).We used a licensed version of the software to design our questionnaire survey and sent the link to all who participated in the online discussions, using D-Agree. 201 participants (female = 49; 24.3% and male = 152; 75.6%) participated in the survey.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

3.3 Discussions and survey instrument

A divergence discussion phase was selected for online discussion of this study. Discussion at D-Agree is divided into the following three phases: divergence, convergence, and evaluation. Divergence phase was chosen because we can collect a wide variety of opinions on the discussion themes. (Haqbeen et al. 2021). We selected seven discussion topics or raisedquestions and discussed possible solutionsto the challenge ofsolid waste management (SWM) inKabul city.Each of the seven themes covering different aspects of SWM lasted for one week. Based on participants' engagement with these themes, they were scored and ranked by the system in real-time within their related groups. They all discussed the same topics within the same time while using different spaces.

A closed-ended questionnaire was used to elicit responses during post online discussions.The questionnaire was divided into different sections, comprising questions on: (i) personal and demographic information; (ii) motivations for participating in online discussions; and (iii) effect of social influence from online discussions on knowledge and behavioural change. The two main questions related to the dependent variables were presented, using multiple-choice and Likert-scale. These questions were phrased thus:“What motivated you to participate in online discussions?” and“Didparticipation in online discussions affect your thoughts and result in behaviour change?” The first question contained 7 items related to preferred motives (multiple-choice), while the second was a five-point Likert-scale-type question.

3.4 Datasets

The survey data was digitised and analysed with the help of STATA/SE 16.1. There was no missing data, whether user and system-based. Indeed, the response rate from the 201 respondents was 100 percent. A reliability test was conducted to ensure that the data had internal consistency.Regarding the validity of the analyses of the data generated throughLikert-scale-type questions, we used mean values and t-tests. In addition,descriptive analysis enabled us to disentangle the demographic characteristics of the respondents and their means of preferred motives.

4 RESULTS AND DISCUSSION

4.1 Demographics of the sample

Table 1 shows the characteristics of respondents who responded to the SurveyMonkey questionnaireused for this study. There were 49 (24.38%) females compared to males which accounted for 76 percent of total respondents in this study. Many factors could explain the low representation of women in the survey. First, literacy rate among Afghan women is abysmally low at 29.8 percent compared to that of men, which stands at 55.48 percent(World Bank 2018). Second, reports from the Afghanistan Communication and InformationTechnology Ministry (MCIT) statistics indicate that access to internet and smartphones is lower among women (smartphone users = 32%; access to internet = 39%) compared to men (smartphone users = 68%; access to internet = 61%). Note that this comparison is based on all internet users which only constitute 11.4% of Afghanistan's population to the physical space.Finally, social and cultural barriers such as the pressure of care and domestic work may adversely affect the time that women could devote to online networking and discussions (Sahab et al. 2016). These factors cumulatively exclude women from meaningful engagement in economic, social, and political spheres of life compared to men (Breath, 2012).

The highest number of respondents (n = 90; 44.78%) out of all the six age groups were 25-34 years old. This finding may be explained by the demographic composition of the Afghan population, with a large representation of young people (NSIA, 2021). It may also be due to the stylised fact that young people (millennials) tend to be more technologically curious and savvy than older generations (Volkom et al. 2013). Most respondents (n =78; 38.815) held a bachelor degree. This may have been informed by our use of an online survey forum which tends to be biased in favour of educated individuals, compared to the use of conventional survey tools during field visitations (Sahab et al., 2015, 2016). Most respondents were employed (65.98%) while a considerable number of them were still in school (20.10%).

4.2 Respondent's motives for participating in online discussions

The analysed results on respondents' motivations for participating in online discussions are shown in Fig. 1.The results showing the age-specific motivations of the respondents are shown in Fig. 2. Finally, the results on the gender-specific motivationsfor participating in online discussionsare shown in Fig. 3.

		Participant	Percentage
Valid		201	100.0
Excluded		0	0.0
Age	18 to 24	27	13.43
	25 to 34	90	44.78
	35 to 44	65	32.34
	45 to 54	13	6.47
	55 to 64	5	2.49
	≥65	1	0.50
Gender	Female	49	24.38
	Male	152	75.62
Education	Less than High School	2	1.00
	High School	28	13.93
	College	53	26.37
	Bachelor	78	38.81
	Master's	34	16.92
	PhD or Higher	6	2.99
Employment	Government Employed	18	9.28
	Private Sector Employed	48	24.74
	Self Employed	62	31.96
	Retired	4	2.06
	Not Employed	23	11.86
	Student	39	20.10

Table 1. Characteristics of the respondents for the current study (n = 201).

The analysis of the motivation to participate was predicated on multiple response questions, as mentioned in Section 2.2. Cash prize for winners (66.67%) and certificate for winners (50.75%) were the first and second preferred motivators, respectively,for participating in online discussions among the respondents from a list of seven motivators suggested in the questionnaire (Fig. 1). However, the motivationsfor participating in online discussions do not significantly differ based onrespondents'age groups or gender (Figs 2-3).

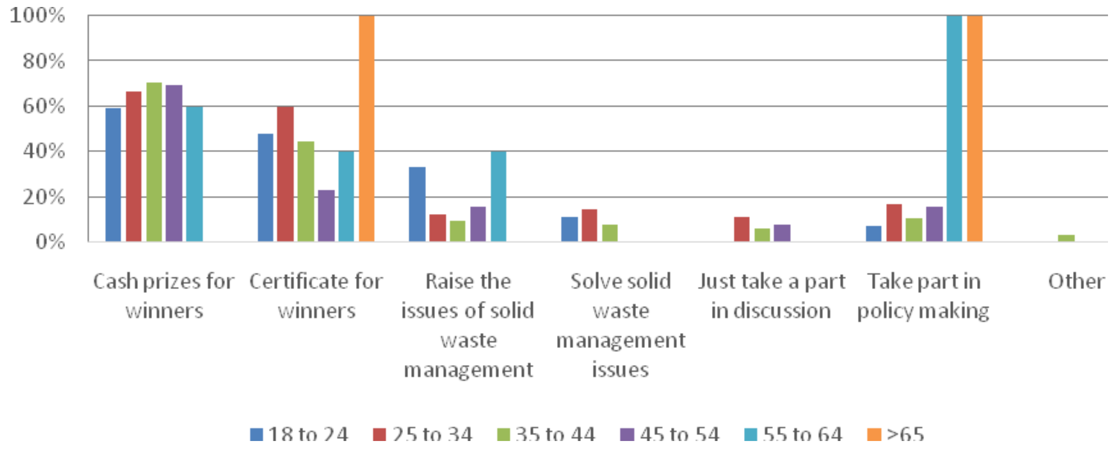

Fig. 2: Motivational factors to participate by age groups

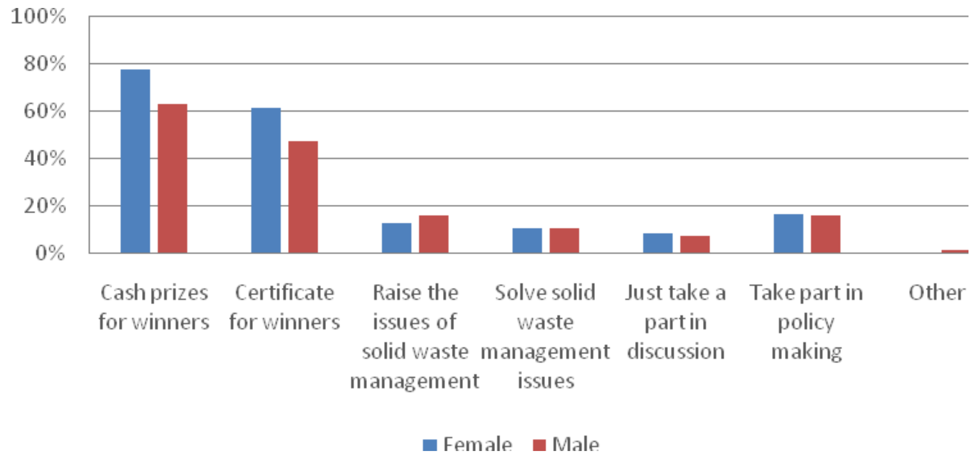

Fig. 3: Motivational factors to participate by Gender

4.3 Social influence of participants and overall discussion

The analysed results on the influence of other participants in online discussions are shown in Fig. 4, while those related to the prospect of attitudinal and behavioural change in relation to SWM due to participation in online discussions are shown in Fig. 5.

To understand the influence, we used two single choice questions. We asked participants if they were influenced by other participants' opinions and if the discussions brought any changes in their behaviour regarding waste management. We demonstrate that the opinions of other participants expressed in online discussions had a significant influence on the participants, as alluded to by 51.24 percentof the respondents who reported a great deal or a lotof influence. Another 46.27 percentof them claimed to be moderately influenced by other participants' opinions, while only 2.49 percent reported little or no influence of online discussions on their opinionstoward SWM (Fig. 4). However, there was no evidence that the age or gender of respondents affected their perception of the influence of online discussions on their opinions. The results of the question about the behaviour change (Fig.5) was similar to that of influence of online discussions on participants (Fig. 4). Specifically, most participants (51.74 percent) reported that the discussions had changed their behaviours a great deal or a lot, while 43. 28 percentopined that their behaviourshad moderately changed. However, 4.98 percent of the respondents believed that their behaviour had changedonly a little or remained unchanged. Like the reciprocal influence of the opinions of other participants in the online discussions, we did not find any significant difference in behavioural change towards SWM based on respondents'ages and gender.

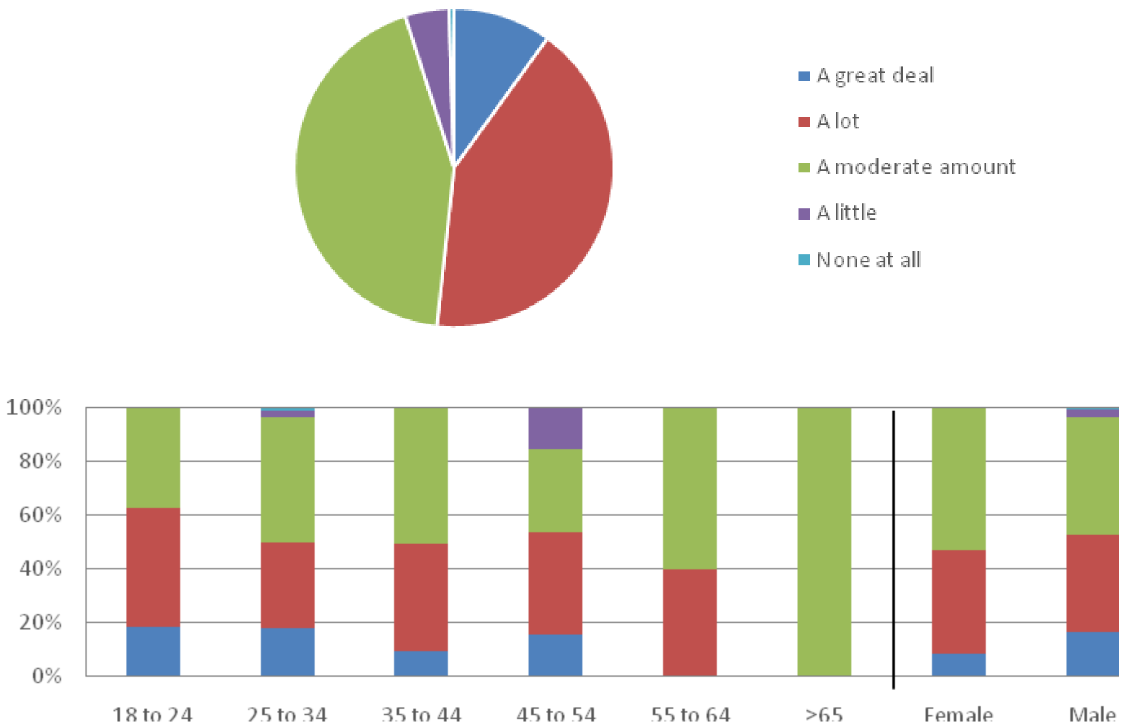

Fig. 4: (top) Overall influenceof other participants' opinions in the online discussion, (bottom) Influence of other participants opinions by age and gender

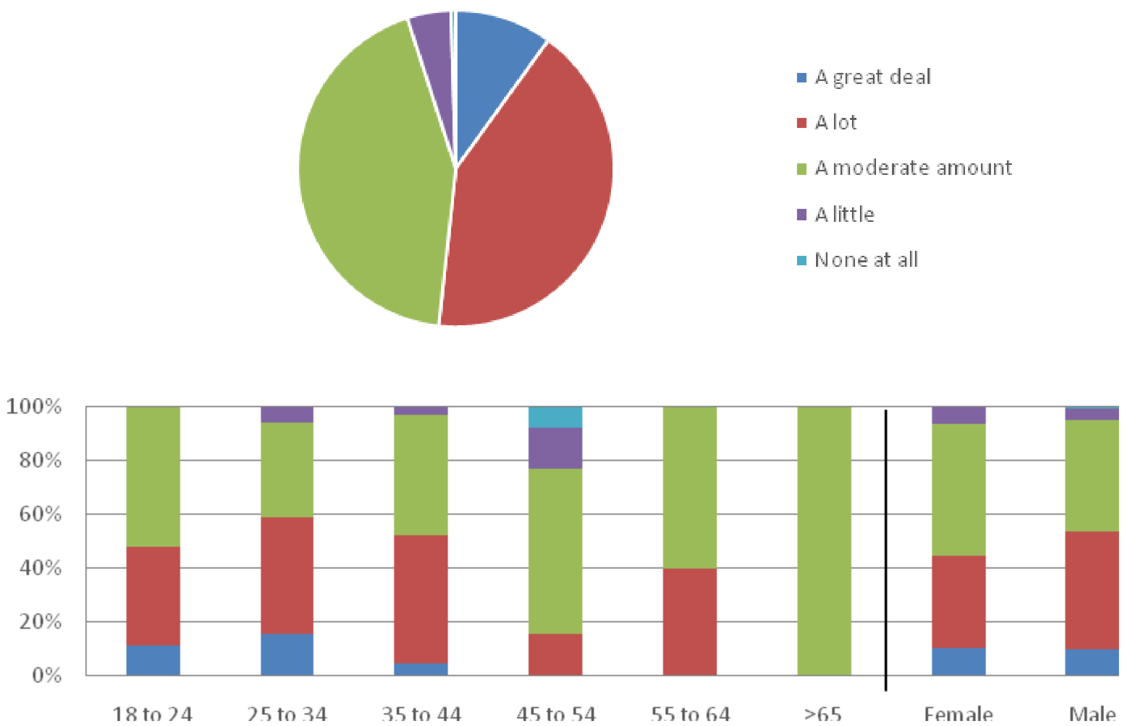

Fig. 5: (Top) Overall behaviour change toward solid waste management due to participation in the discussions, (bottom) behaviour change on solid waste management caused by age and gender.

5 CONCLUSION

This paper proposesa municipal idea contest project,to discuss a real urban issue of Kabul City, solid waste management (SWM), using our proposed online forum in an incentivized setting. Our research project's main approach was not only harnessing the wisdom of crowd for offering SWM innovative solutions to KM, but

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

also, we aimed at identifying the factors as motives that are most likely to stimulate user's participation, and their engagement in activities in online discussions. In particular, we designed a questionnaire as a post-discussion survey instrument and called all subjects who had taken part in the municipal idea contest project online discussion to take part.

According to online survey (201 respondents who had taken part in both online discussion and post discussion survey), the financial (66.67%) and social (50.75%) incentives were the two primary motivators of respondents' decision to participate in online discussions of all the seven suggested motivators in the study. This demonstrates that the use of incentives (monetary and social rewards) in asynchronous online discussions could facilitate interactivity and mutual exchange of opinionsamong users. We also showed that these motivators do not significantly differ based on respondents' age groups or gender.Finally,our study shows that the social influence of online discussions on participants ranges from moderate to a great deal, but this effect does not vary significantly based on participants' age groups or gender. These findings offer promising prospects for scholars, researchers and policy makerson how best to engage people in mutually beneficial online discussion platforms. Moreover, like the KM's initiative to improve SWM which has been the focus of this study,efforts to track and change citizens'knowledge, attitudes and behaviours towards progressive dimensions through advocacy could benefit from the findings of this study.

After all, this is the first study of its kind conducted to offer an innovative solution for Kabul city SWM which was established through crowd and the medium of online discussion support platform. Considering the cross-sectoral aspect of harnessing the wisdom of crowd, the finding of this study will contribute to conducting crowdsourcing projects to many other areas of Kabul City such as water, transportation and the environmental issues.

5.1 Limitations and future perspectives

The main limitation of our study is perhaps the use of open and convenience call for post-discussion survey. Although it may have become popular asa formal method of accessingrespondents (female and males) and collecting data on various issues, the fact that Afghans tend to participate in incentivized tasks in online communities made the sample collection a bit difficult for post-discussion survey.The post-discussion survey could also benefit from incentives. In addition, Afghan males tend to predominate in online communities made the sample a bit biased in their favour compared to females due to sociocultural constraints on women's use of time and networking. Therefore, we hope to consider including two equal sample strata (splits) to female and male respondents, using a stratified random sampling technique in our future work. Furthermore, we believe that the skewed sample in favour of highly educated respondents constitute a limitation to the representativeness of our sample. Therefore, we shall also endeavour to boost our samples to incorporate respondents with different levels of education, especially as waste management issues, the focus of our online discussions in this study is generally presumed to be more pressing among poorer and less educated population. Finally, we plan to conduct further experiments, using two groups of respondents: a controlled group without the prospect of benefiting from any incentive mechanism for participating in online discussions and a treatment group with the prospects of benefiting from incentive mechanisms for participating in the discussions. This will enable us to provide a more robust statistical evidence on the actual determinants of participation in online discussions based on the data generated from the post-discussions survey.

1 ABSTRACT

The world population is growing, and a majority of the population is and will be living in urban areas. Nearly 90 percent of this growth takes place in Asia and Africa. However, urbanisation processes are not distributed evenly. Mostly they are concentrated in prosperous regions, at infrastructural nodes, or along trade routes. The so-called New Silk Roads are new trade routes where massive investments are currently made to connect China with the world. The aim of this study is to analyse the dynamics of spatial urbanisation in spatial proximity to the New Silk Roads. In detail, we want to test the hypothesis whether higher spatial growth rates are recorded for cities along these routes than for cities in the same region but away from the New Silk Roads.

For this task, we apply remotely sensed data. In this study, we extracted urban areas from multitemporal Landsat data for the time period of 1990 to 2019. We classify settlements using a Random Forest (RF) supervised classification technique. We used Gray-Level Co-Occurrence Matrix (GLCM) texture features together with spectral indices as feature set. We derive training data for our classifier by a stratified sampling method using geoinformation from the Global Human Settlement Layer (GHSL) and the ESA annual Land-cover data. The resulting consistent classifications of urban areas have temporal intervals of 5 years, i.e. 1990,1995, 2000, 2005,2010,2014, 2019 and feature high accuracies.

We selected cities with over 300,000 inhabitants. We define cities in proximity to the New Silk Roads (NSR cities) within a 100 km distance vs. cities with at least 100 km distance from the NSR (non-NSR cities); these cities are located in China, central Asian countries such as Kazakhstan, including Iran, Turkey, and Russia. We quantitively analyse spatio-temporal urban expansion trends for both groups, NSR, and non-NSR cities, for testing our hypothesis. To do so, we applied various urbanisation indices such as Overall Built-up Changed Area (OBAC), Annual Expansion Area (AEA), and urban Expansion Rate (ER).

Generally, our results reveal that spatial urbanisation is increasing over the last almost 30 years in all cities among our sample. The spatial comparison of our two groups of cities reveals that our hypothesis can be confirmed: from 2014 to 2019, urban expansion in cities along the New Silk Road was significantly faster with an annual expansion rate of 339 km2 compared to 113 km2 in cities spatially distanced from the New Silk Roads. This trend did not exist before the year 2010.

Keywords: Landsat, Remote Sensing, New Silk Road, Urbanization, GHSL

2 INTRODUCTION

Urban areas have been expanding over the past decades, and it is predicted that the world population will further increase in the coming decades. According to the latest UN report on World Population Prospects (United Nations, 2019), the world population reached 7.7 billion in 2019, indicating that the global population has grown by over one billion people over the past 14 years. Sixty-one percent of the global population lives in Asia (4.7 billion), and 1.44 billion in China alone. With it, China is the world's largest country in terms of total population. In recent decades China has experienced the highest growth rates both in population and urban areas (Taubenböck et al., 2014; Shi et al., 2019) .

The Sustainable Development Goals (SDGs), particularly Goal 11 and the UN New Urban Agenda, call countries to develop National Urban Policies and strategies as an essential part of achieving economic, social, and environmental goals. Therefore, public authorities are in need of information about urban dynamics, dimensions, and forms to understand current processes and its impacts. This knowledge must be the basis to develop policy strategies for urbanisation challenges (SDGs, 2020). The most obvious change is the physical expansion of urban areas. Traditional field data collection is not viable, and conventional urban data sources are often outdated and hard to obtain (Taubenböck et al., 2009). In order to be able to map and describe this urban expansion, current, large-scale data sets are needed. Remote sensing data have become a valuable source for large-area, multi-temporal and consistent classification of settlement areas. Many studies investigated the extraction of built-up areas from medium resolution data (e.g. Doustfatemeh and Baleghi, 2016; MacLachlan et al., 2017; Verma et al., 2018). The detection of urban areas at a global scale is evolving from coarse to medium resolution open-source Earth Observation (EO) data, taking advantage of methodological and technological advances. For example, the Global Human Settlement Layer (GHSL) generated at 30m resolution (Pesaresi et al., 2016), the artificial surfaces mask of the GLOBELAND30 – GLC309 (available at 30m resolution and referring to the year 2010), (Chen et al., 2015) or at 12-meter resolution the Global Urban Footprint (GUF) (Esch et al., 2012).

Cities often developed in favorable locations. For a long time, locations on rivers or by the sea were decisive locational advantages (e.g. Kostof, 1991). The existing or future planned infrastructure is also a key locational advantage. Infrastructure nodes are one central attraction point. In general, urban areas are expected to grow further by more infrastructure development (Aljoufie et al., 2011). In 2013 the Belt and Road Initiative (BRI) was announced by the Chinese Government (Suprabha Baniya et al., 2019); this initiative is aiming at the revival of the old Silk Road, which is now referred as the New Silk Road (NSR). The planned NSR is developed based on the ancient land-based routes (Ni et al., 2017). The rise and fall of cities along the historical Silk Road are closely linked to the trade's rise and fall (Ni et al., 2017). Some studies predict that cities located along the NSR are expected to have higher growth rates due to the advancement of infrastructure connection and an expected thriving economic future (Jakóbowski et al., 2018).

Since the New Silk Road initiative's inauguration, several scientific studies related to this project have been published. However, the majority of studies explored non-urban aspects; these topics include international political economy and geopolitical economics (e.g. Lee et al., 2018; Summers, 2016; Suprabha Baniya et al., 2019), Chinese foreign policy implications (e.g. Ferdinand, 2016; Wang, 2016), the framework and assessment of the Belt and Road initiative in general (e.g. Chan, 2018; Cheng, 2016; Huang, 2016). Few studies explored aspects of urbanisation: Chen et al. (Chen et al., 2019) studied urbanisation patterns and poverty reduction on the country level for nations along the Belt and Road initiative from 1996 to 2016. Feng et al. (2017) studied spatial patterns of the urban system along the NSR using DMSP-OLS night-time light data; they analysed 273 main cities in 1992, 2003, 2014 and found that the number of relatively small cities is decreasing, and the number of large and medium-sized cities is increasing. To date, geopolitical and geo-economic aspects of the NSR have been investigated, the urbanisation aspect, however, remains mostly unexplored. In this study, we intended to investigate if spatial urban expansion along the NSR outgrows these cities far off the NSR.

2.1 Background

The ancient Silk Road was a network that connected East to West (130 B.C.- 1453 A.D.). The transportation means were camels or horses. Stops were needed for transit and food supplies. For these reasons, settlements along the Silk Road gradually became central to the trades where people and goods gather, the merchants exchanged their goods and made their transactions. These activities led to the formation of a significant number of large ancient cities along the NSR (Ni et al., 2017). The rise and fall of these ancient cities along the ancient Silk Road were closely linked to the success and fall of the trades. Thus, it is expected that the revival of the Silk Road may accelerate the expansion of the NSR cities, even the emergence of new cities. Farkhod et al. (2019) showed most of the NSR connectivity projects that are implemented and planned in the frame of the NSR projects located in central Asian countries (Table 1). These projects have been initiated to improve existing and build new infrastructure between these cities and countries, which are today only poorly linked with each other. It has been shown that transportation and economic development strongly correlate with population growth and spatial expansion of cities (Aljoufie et al., 2011). Therefore, it is expected that the NSR and its connectivity projects trigger urbanisation in the cities connected to it.

Study area

We selected all cities with over 300,000 inhabitants along the New Silk Roads (NSR cities). We defined cities within a 100 km corridor along the NSR (NSR cities) as connected to the new infrastructure development. At the same time, we selected the same number of cities per country that are further than 100km from the NSR (non-NSR cities). We understand them as too far away for direct impact by the NSR; these cities are located in China, Kazakhstan, Kyrgyzstan, Tajikstan, Turkmenistan, Iran, Turkey, and Russia (Figure 1). We use these two groups of cities to compare urbanization rates.

Country	Projects	Total funding(mln USD)
Tajikistan	16	4515.9
Kazakhstan	14	14539.3
Kyrgyzstan	11	1773.04
Turkmenistan	5	1402.5
Uzbekistan	5	1269

Figure 1. Geographical location of NSR and non-NSR cities

2.2 Data

For spatiotemporal analysis of urbanisation in a large study area, earth observation data proved to be an independent and cost-effective data source allowing for sufficient accuracy (e.g. Taubenböck et al., 2012). In this study, we selected – due to the need for wide area and for a 30-year temporal coverage from 1990 until today – data from the Landsat program. Data from the TM (Thematic Mapper), ETM+ (Enhanced Thematic Mapper plus), and OLI (Operational land Imager) sensors are available for our monitoring period with a comparatively high spatial resolution of 30m.

The settlement classification is performed in combination with the existing GHSL layer (Pesaresi et al., 2016), which contains a built-up area extent for 1990, 2000, 2014. We used the cloud-based platform Google Earth Engine (GEE) to process the available Landsat data. The GEE public data catalog contains an archive of multi-Petabyte of historical and present satellite imageries, especially the entire Landsat archive from Landsat-1 to Landsat-8. The GEE archive is updated every day with around 6000 new scenes from active earth observation satellite missions (Gorelick et al., 2017).

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

3 METHODOLOGY

The developed workflow for mapping settlement areas from remote sensing data and the analysis of their spatial expansion over time included four methodological steps (Figure 2): Image-preprocessing, classification, validation and analysis of urban expansion.

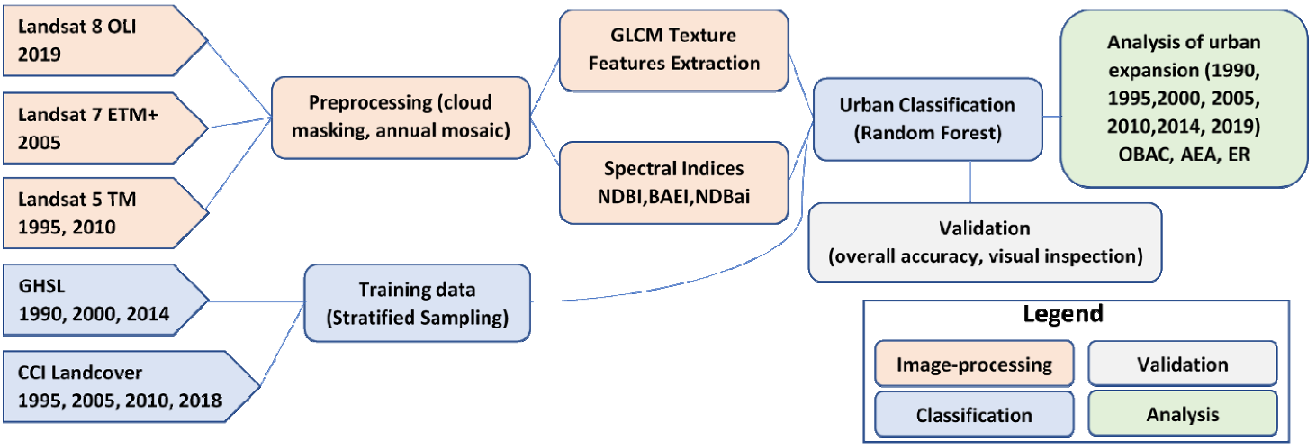

Figure 2. Overview of the methodological steps

The first step was image pre-processing, which included cleaning from cloud contamination. Surface reflectance data has been combined with a cloud mask to mask out the cloud-contaminated areas. Subsequently, annual mosaics using the median, i.e. the median value of the correspondent pixel from all available scences for the entire year have been constructed. For processing, we applied a circle buffer with 70 km diameter (equivalent to the diameter of the biggest city in the study area) around the cities' point location. In order to have a comparable spatial baseline for the cities, we applied the 'morphological urban areas' as introduced by Taubenböck et al. (2019). The morphological urban areas delineate the city from the countryside in a consistent manner along a density gradient. As this is done in a consistent manner for all cities, the spatial units are comparable, unlike historically created administrative boundaries of cities.

In a second step, we developed a feature space consisting of three GLCM texture features: variance, contrast, dissimilarity of each of the seven bands of the Landsat data. In addition, three spectral indices NDBI, BAEI, NDBai were used. These are introduced in the next section in detail. Overall, we produced a feature space with a total of 24 input variables.

The third step was classification; we generated the training data using stratified sampling from the GHSL and the ESA land-cover data as the base layer. This method takes previously produced land-cover information and returns the specified number of training points per class, considering the spatial distribution and other parameters like disproportional sample number per class area for better training data. A random forest supervised classification approach was carried out to classify the urban areas.

The fourth step was validation of the classification results; one-third of the training data were used to evaluate the overall accuracy of the RF classifier. In addition, we also investigated the results visually.

3.1 Multi-temporal land-cover classification

A land-cover classification extracting ten thematic classes (rainfed agriculture, irrigated agriculture, vegetation, forest/tree, shrubland, grassland/rangeland, bare land, water, snow, and built-up area) was performed on an individual basis, for each time step, and for each study sub-region. The main purpose of this classification was to identify urban built-up areas for the spatio-temporal measurement of urban expansion. In this study, we adopted the definition 'urban areas' as introduced by Schneider et al. (2010). This definition relates to places that are dominated by the built-up environment. The built-up environment includes all non-vegetative, human-constructed elements, such as buildings, roads, runways, etc. (a mix of human-made surfaces and materials). 'Dominated' implies coverage greater than or equal to 50% of a given landscape unit (here, the pixel). Pixels that are entirely covered by vegetation (e.g., a park) are not considered urban, even though they may function as urban space in terms of land use.

We applied the supervised random forest (Breiman, 2001) algorithm to classify urban areas. The classifier relies on the combination of texture features and spectral indices (Bramhe et al., 2018; Lu et al., 2005).

Satellite images not only contain spectral information encoded in different wavelength channels but they also feature rich information in terms of context or spatial information. To extract the urban areas effectively, the inclusion of the contextual and neighborhood information has been shown beneficial. Given that, each class or object pixels shows prominent characteristics in line with neighboring pixels. Therefore, textural image information such as the Gray-Level Co-Occurrence Matrix (GLCM) (Haralick et al., 1973) has proven meaningful for higher classification accuracy. The calculation is based on tonal (DN) differences between pairs of pixels in a spatially defined relationship with consideration of all pixel pairs within the neighborhood. Bramhe et al. (2018) reported the advantage of using Grey-Level-Co-occurrence-Matrix (GLCM) texture features together with spectral indices the extraction of built-up areas with higher accuracy. In line with this, we applied the Normalized Difference Built-up Index (NDBI), the Built-up Area Extraction Index (BAEI), and the Normalized Difference Bareness Index (NDBai). We applied the variable importance (VI) measure to optimise input variables. Based on the empirical results achieved, a total of 24 input features have been identified that contributed the most to the final result: The GLCM texture features variance, contrast, dissimilarity of each of the seven bands of the Landsat data as well as the three spectral indices NDBI, BAEI, NDBai.

We selected training data for training the classifier using a stratified sampling method (Millard and Richardson, 2015). The ESA Climate Change Initiative (CCI) (ESA, 2017) annual land-cover data were used as spatial reference for non-built-up classes. The GHLS was used for training data selection within built-up areas. The training data have been extracted separately, and the classification was run to ensure higher classification accuracy. Based on the empirical result, 2,000 training points per non-built-up land-cover class and 4,000 training points for the built-up class yielded a good result. The built-up areas' training points are further filtered with an NDVI threshold to exclude all points that have a higher value of the specified NDVI threshold to improve built-up area detection accuracy. The NDVI threshold was achieved through empirical results observing the classification accuracy.

The final classification result was then re-classified into three thematic classes: 'water', 'land', 'built-up area'. The following classes have been merged to the 'land' class; forest/tree, shrubland, grassland/rangeland, bare land, and snow. For accuracy assessment, one-third of the generated point data being independent from the trainnig data were used to evaluate the overall accuracy of the RF classifier. The accuracy assessment has been utilised for each run per study subregion.

A post-processing filter has been performed to exclude outlier pixels that were misclassified for the year 1995, 2005, 2010. The mask was taken from the GHLS layer that contains a permanent land thematic built-up class which remained stable from 1975 to 2015; this thematic class has been used to mask out few misclassified pixels to increase the classification accuracy.

3.2 Spatial units for comparison of cities

For a consistent analysis and comparison of urban spatial growth across cities, it is essential to select a suitable Urban Boundary (UB) that can correctly divide urban and rural areas (Xue et al., 2018). However, administrative units do not provide consistent units. Therefore, this unit has been shown to be inadmissible or distortions occur in comparative urban analysis (Wang et al., 2018). One suggested solution is using an UB that is generated using a harmonised and data-driven method applied for all cities. In this study, the Morphological Urban Areas (MUAs) developed by Taubenböck et al. (2019) were used as UB for further analysis. The MUAs delineate urban from rural along a decreasing built-up density from the centre to the periphery. The advantage of the MUAs are that they consistently delineate cities. Further information on the MUAs methodology can be acquired from Taubenböck et al. (2019). We calculated the extent of built-up areas in square kilometer and area-related indices for all cities based on the respective UB.

3.3 Measuring physical expansion of cities

The higher-ranking goal of this study was to test whether spatio-temporal expansion of NSR cities is higher than in non-NSR cities. To do so, we applied urbanisation indices. Urbanisation indices are used to measure the extent and speed of urbanisation over time. We used three indices: The Overall Built-up Changed Area (OBAC) measures the amount of changed built-up area between two-time steps, the Annual Expansion Area (AEA) measures the amount of annual urban expansion, and the urban Expansion Rate (ER) index is used as

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

an indicator of urbanisation speed (Qian and Wu, 2019; Haas, 2016). The formulas of the three indices are introduced below.

Overall Built-up changed Area OBCA = BA (t2) - BA (t1) (1)

Annual Expansion Area AEA = [BA (t2) - BA (t1)]/(t2 - t1) (2)

Expansion Rate ER = ([BA (t2) - BA (t1)]/ BA(t1))*100 (3)

BA stands for the built-up area, BA(t) refers to the amount of settlement areas in particular time steps. The letter (t) refers to the time, and t1 is the prior time of t2.

3.4 Results: Spatio-Temporal Analysis of Urbanization along and off the New Silk Road

In general, we measured cities along the New Silk Road with higher urban growth rates than cities spatially off the route. This result confirms our central hypothesis.

Figure 3 illustrates the spatio-temporal evolution of settlement patterns from 1990 until 2019 for the examples of Almaty (Kazakhstan) and Kermanshah (Iran). Almaty is a city along the NSR, and Kermanshah is a sample city off the NSR by our definition. In addition, the morphological urban areas are shown in the figure to encompass the main settlement. The figure shows urban growth in general, but it is particularly interesting to see how growth in Kermanshah occurs along linear structures.

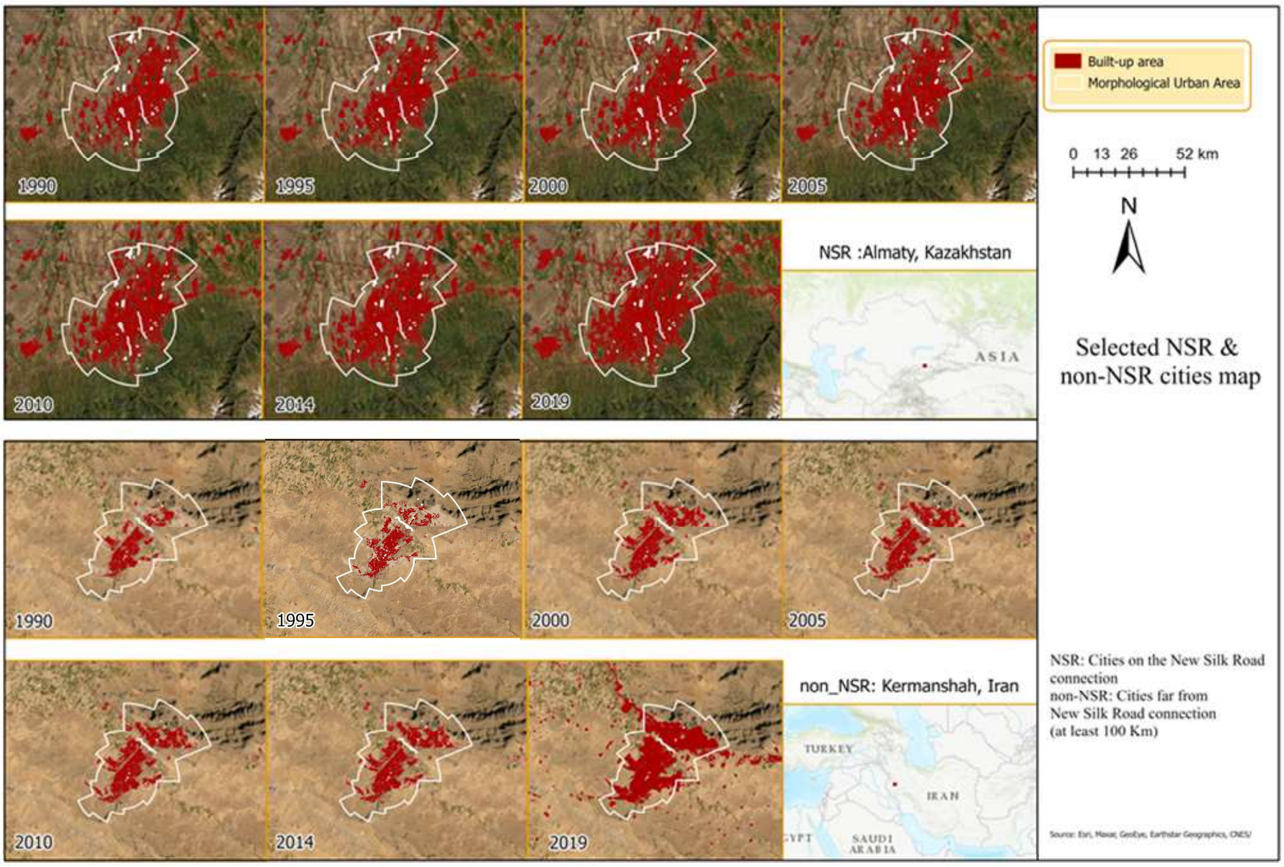

Figure 3. Classification result for NSR and non-NSR studies

We have evaluated the classification accuracy during the classification process; we used one-third of the training sample to evaluate the classifier's performance, while the remaining two-thirds were used to train the classifier. We measured the overall accuracies range from 75% to over 90 % dependeding on the particular city.

We have calculated the total urban area in square kilometers of all cities for each period, and we have calculated the area-related urban indices (OBAC, AEA, ER) to measure and quantify the magnitude of urban expansion in NSR and non-NSR cities. The total built-up area for the NSR cities detected in the initial year of our study 1990 was 4230.93 km2. We measured an increase to a total built-up area of 7926.06 km2 in 2019. In contrast, the total built-up area for the non-NSR cities was 1154.77 km2 in 1990 and then increased to 2919.52 km2 in 2019.

To investigate further the degree of change in both groups of cities, the three utilised urbanisation indices are calculated and they are as follows: The OBCA index, which shows the changed built-up area at two-time steps, and the AEA, which shows the annual expansion area, reveal that there has been generally fluctuating urban growth rates over the five year or yearly time periods. However, what is particularly interesting here is that from 2014 onwards, i.e. after the New Silk Road was launched as a project, the absolute area growth of the cities has been measured highest by far (Table 1).

year	1990-1995	1995-2000	2000-2005	2005-2010	2010-2014	2014-2019
NSR cities	1026 (205)	223 (45)	333 (67)	232 (46)	185 (46)	1696 (339)
Non-NSR cities	654 (131)	80 (16)	253 (51)	155 (31)	60 (15)	563 (113)

Table 2: Overall Built-up Changed Area (OBCA) and Annual Expansion Area (AEA) in km² (rounded)

For a relative analysis, we calculated the ER, which is used to capture the speed of urbanisation for the study periods. The ER compares the amount of urban land of two-time steps as a relative measure of urbanisation speed. The results of the ER index show that NSR cities expanded compared to non-NSR cities at a relatively slower speed from 1990 to 2010. However, we measured from 2010 onwards that the expansion speed of NSR cities overtakes the non-NSR cities (Table 3).

year	1990-1995	1995-2000	2000-2005	2005-2010	2010-2014	2014-2019
NSR	24.25	4.25	6.08	3.99	3.06	27.22
Non-NSR	56.64	4.40	13.40	7.24	2.61	23.90

Table 3: Expansion Rate (ER) in percent

Overall, we found that spatial urbanisation significantly increased from the years 2010 and onwards, independent whether cities are along the New Silk Road or not. At the same time, the analysis showed that urban expansion along the New Silk Road accelerated in the last decade. While until 2010 growth rates were actually slightly higher in non-NSR cities, we see that from 2010 NSR cities have higher growth rates.

4 DISCUSSION

It is interesting to see, that our main finding, that urban expansion is from 2010 onwards higher in NSR cities than far off the New Silk Roads, coincides with the inauguration of the NSR. However, we must clarify that our analysis is only descriptive and shows an effect that demonstrates a possible consequence of investments along the trade route. But, we cannot establish a clear causal relationship here due to the data situation as well as due to the manifold possible influencing factors.

This increase of urbanisation rates in the last decade coincides with the inauguration of the NSR. After the announcement of the BRI initiative, many projects were implemented to build as well as to reinforce the necessary transportation infrastructure to connect NSR cities and to ultimately connect China and the participating countries to Europe. It is well accepted that new economic opportunities in the cities attract more urban dwellers and consequently result in the expansion of cities. Based on the result achieved in this study, the result indicates an increased growth of built-up areas in NSR cities. Thus, there appears to be a link to increased urban growth rates.

With respect to our input data, we have measured an overall high accuracy of classification results. However, the effects of misclassifications to our results must remain unclear here. In addition, we measured for the period from 1990-1995 very high growth rates for all three urban indices. These are related to methodological differences, where higher settlement detection rates were performed in 1995 compared to 1990 due to an improved data situation. Thus, we assume growth rates from 1990 to 1995 overestimated in our analysis. From 1995 onwards, however, results are consistent and plausible. Beyond, by the applied method in this study some challenges in mountainous regions were observed; the geological structures and terraces similar in spectral reflectance to settlements were also included as built-up areas. Their effect, however, was low as these misclassified pixels were mostly excluded using the morphological urban areas in the final analysis.

5 CONCLUSION

In this paper, we have investigated the spatial urbanisation trend in cities along the NSR in comparison to cities off the NSR. We found that, indeed, NSR cities feature increased urbanisation rates since 2010 and

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

higher urbanisation rates than cities spatially not directly connected to the NSR. Beyond, the results of the analysis confirm the accelerated growth cities in the study region in the recent decade in general. Although we cannot establish a causal relationship here, the NSR initative with its developed projects seems to trigger these expansion rates.

Remote sensing proved to be a reliable tool for large-scale analysis of urbanisation trends. The proposed method of extracting urban areas using medium resolution multitemporal Landsat data resulted in acceptable classification accuracies. In linking these spatial data with other data on economic, demographic, social or environmental issues, we see a high potential for new scientific insights along such a megaproject. Beyond, from a remote sensing point of view, we encourage further research with higher resolved satellite data to investigate this topic more in-depth. As the New Silk Roads will expand beyond our study areas, further studies are encouraged systematise and confirm the identified trends.

1 ABSTRACT

Informal settlements have been a recurring problem in South Africa and it is undeniable that eradication of informal settlements is a goal difficult to achieve. However, the fundamental problem is not the mere existence of informal settlements but, the poor quality of life the residents are subjected to. Since 2004, South Africa has embarked on a journey to improve the quality of life of informal settlement dwellers through the implementation of Upgrading of Informal Settlement Programme (UISP). Not only did the state recognise that upgrading informal settlements can be a viable solution to the housing backlog but also acknowledged that housing strategies that relocate the poor have a significant impact on the livelihoods of the urban poor. Thus, UISP is set to achieve effective informal settlement upgrading through ensuring minimal disruption to livelihoods, encourage community empowerment and community participation. The paper presents results of a study conducted on the implemented UISP in Slovo Park informal settlement. The study is conducted using a qualitative approach which entails in-depth interviews with ten residents of Slovo Park and two City of Johannesburg officials on the possible impact UISP has on improving quality of life. This paper reveals how effective is UISP in ensuring land tenure security for the urban poor. Furthermore, the paper highlight factors that hinders the effectiveness of UISP. Results from this paper can be used to monitor and review the outcomes of in situ upgrading by highlighting the shortcomings in the planning and implementation process. In addition, findings from this study could assist the National Department of Human Settlements in achieving successful in situ upgrading by improving the UISP process using recommendations provided.

Keywords: Community empowerment, informal settlement, in situ upgrading, livelihoods, quality of life

2 INTRODUCTION AND CONTEXTUALISATION

South Africa has experienced influx of migrates to major cities over the past two decades (Ziblim et al., 2013). Socio-economic inequalities have left many poor households unable to provide for their needs including accessing shelter and or adequate housing. Despite the over 1 million new houses built since 1994, the South African new democracy has since been battling with meeting the growing housing and infrastructure demand. Particularly in metropolitan cities such as Cape Town, Johannesburg and Ekurhuleni, leaving many families resorting to seeking affordable accommodation in informal settlements or backyards of formal residence units in the townships (Møller, 2007). Nonetheless, formation and expansion of informal settlements has been a challenge faced by most developing countries. Many among them initially pursed forced eviction and demolition of existing informal settlements as an 'easy' way to eradicate informal settlements. This practice has made the residents of informal settlements poorer as the vacant land created through eradication of informal settlements is later, amongst other things, commonly used for development of luxury housing units, and shopping centres, benefiting the upper class (Arimah & Branch, 2011). The third UN Conference in Istanbul in June 1996, launched the Istanbul Declaration on Human Settlements, which brought change in the global policy dialogue on the need to ensure adequate shelter for all. This policy agenda was later renewed within the framework of the UN Millennium Development Goals MDGs, which indicate under Goal 7 Target 10, to expressively enhance the lives of more than 100 million informal settlement dwellers by the year 2020. Developing countries had to oblige by this target, thus instituted various programmes aiming at improving informal settlements (Ziblim et al., 2013). Although the upgrading programmes do not provide a lasting solution to the development and expansion of informal settlements, some governments have been implementing this approach since the 1980's using funds from the World Bank. The UN-HABITAT and the World Bank established the Slum Upgrading Facilities (SUF) in 2004 with the core objective of summoning domestic capital for informal settlement upgrading undertakings through facilitating links among numerous local actors that possess resources such as financial, technical and political elements of development projects. The UN-HABITAT and the World Bank have also been driving foreign investment from global capital markets to enable funding of upgrading programmes initiated by municipal authorities, nongovernmental organisations, private property developers and utility companies (Arimah & Branch, 2011).

Cities Without Slums (CWS) recognises that informal settlements are characterised by urban poverty, it therefore intends to reduce urban poverty which exists within informal settlements through the SUF programmes that will empower citizens, improve economic opportunities, create jobs and improve governance capacity to manage future urban growth (Arimah & Branch, 2011). Informal settlement upgrading programmes are focussed on improving the environment within which informal settlements exists, also known as in situ upgrading. It is notable that this was a radical change in attitude towards the existance of informal settlements especially in urban areas. Upgrading programmes provided a locality-based enhancement strategies intended to replace the various degrees of undesirability and deterioration in informal settlement through the initial provision of basic social services and physical infrastructure such as water reticulation, sanitation, waste collection, storm drainage system, street lighting, paved footpaths and streets (Abbott, 2002). Huchzermeyer (2011) indicated that compared to previous informal settlement intervention strategies, implementation of informal settlement upgrading programmes is relatively cheap and ensures that livelihoods and social support system are uninterrupted. Given the creative manner in which housing is commonly constructed in informal settlements, the upgrading programme acknowledges that if government provide the bulk infrastructure, formalise the settlements, provide tenure security and improve access to social services, the community is capable of gradually improving their housing structures.

National Department of Human Settlements introduced UISP designed under National Upgrading Settlement Programme as a progressive intervention to eradicate informality in human settlements. One of the main UISP objectives is to upgrade the existing informal settlements incorporating community participation to achieve effective upgrading (Huchzermeyer, 2009). There is much literature focusing on UISP as a strategy to eliminate informality in human settlements (Abbott, 2002; Charlton & Kihato, 2006; Gardener, 2003 and Huchzermeyer & Karam, 2006), however, current studies do not indicate the effectiveness of UISP in improving the quality of life of beneficiaries. The primary outcome of the paper is to inform future human settlement policy by indicating the successes and failures of UISP in improving the quality of life of informal settlement residents. Findings from this paper can also be used to monitor and review the outcomes of in situ upgrading in providing quality of life and improving the socio-economic circumstances of residents of informal settlements by highlighting the shortcomings in the planning and implementation process.

2.1 Conceptual framework: Informal settlements and in situ upgrading

Defining informal settlements requires specific context as its definition varies from culture to culture, social class and often changes with time. Subsequently, the term informal settlements does not apply to all countries. Some countries call them slums, while some call them squatter settlements. Corburn & Karanja (2014) describes informal settlement as a representation of human deprivation to adequate access to safe water, adequate access to sanitation and other infrastructure, poor structural quality of housing, overcrowding, and insecure residential status. According to Amao (2012), an informal settlement can be defined as a residential area which was established without legal claims to the land or permission from the relevant authorities to occupy. These are unplanned settlements and are built in areas that are sometimes unsuitable and environmentally hazardous and using noncompliant building plans. Despite the varied names, informal settlements have similar characteristics. People living in informal settlements have similar circumstances that suggest their informality. These include unauthorised use of vacant public or private land, illegal subdivision and/or rental of land, unauthorised construction of structures and buildings, reliance on low cost and locally available scrap construction materials, absence of restrictive standards and regulations, reliance on family labour and artisanal techniques for construction, non-availability of mortgage or any other subsidised finance. Talukdar (2018) observed that it is becoming commonly acknowledged that in most developing countries, informal settlement is a representation of the poverty trap. People living in informal settlements often exist in conditions that expose them to risk for their health, prosperity, safety and undignified way of life. It is argued that due to their illegal occupation status, informal settlement dwellers have generally limited access to basic social services if at all. Lack of regulation within the settlement have resulted to the overcrowding which contributes to stress where sharing of communal resources such as water stand taps, drainage and toilet facilities is concerned as well as prevelance of crime and violence (Amao, 2012). The South African Department of Human Settlement identifies a settlement as an informal settlement with the following characteristics, which forms the basis of the definition; a settlement in an inappropriate location, a settlement that was formed illegally, an area with restricted public and private sector investment, a settlement overwhelmed with poverty, vulnerability and social stress (Ziblim et al., 2013).

In situ upgrading is a relatively new idea of tackling urban informality challenges instead of eradicating informal settlements. In situ upgrading is an approach focusing on promoting land tenure security by firstly regulating informal settlements. It is also an approach that recognises and promotes maintenance of existing social relationships and community cohesion in informal settlements. Through land tenure legalisation and infrastructure improvements, in situ upgrading aims to gradually improve living conditions of residents living in informal settlements (Khalifa, 2015). Braathen et al. (2014) indicated that in situ upgrading of informal settlements is the state's acknowledgement that informal settlements can form part of a housing solution. It is also the state's recognition that the traditional housing strategies that allocate housing in the periphery of the city have a negative impact on the livelihoods of the urban poor.

3 IN SITU UPGRADING IN SOUTH AFRICA

The Housing White Paper 1994 obligates municipalities to ensure that all residents live in socially and economically integrated communities that sustain livelihoods and provide reasonable access to healthcare, education and social amenities. The policy further states that housing delivery should occur by means of various possible mechanisms because it is government's first and foremost priority to deal with the problem of housing for the poor. The Comprehensive Plan for Sustainable Human Settlements of 2004 brought about various housing strategies to address issues of adequate housing in South Africa. This includes initiations of sites and services, Breaking New Ground (BNG) launched in 2004 (Wekesa et al., 2011). According to Marais & Ntema (2013), the first large scale sites and services project was implemented at the Freedom Square informal settlement and benefited over 100,000 households. BNG projects under the National Housing Subsidy Scheme would provide land, housing and basic services using the project-linked capital subsidy programme also known as the 'Reconstruction and Development Programme' (RDP) housing subsidy. According to Huchzermeyer (2014), BNG also came along as informal settlement eradication strategy in which households qualifying for the one-off capital subsidy were offered the subsidy to later be relocated to an identified area where completed units were allocated. Although this programme provided many poor communities with low-cost housing, residents were disadvantaged because they were commonly relocated to the periphery of the city where economic opportunities are scarce. Providing housing for the poor in the periphery of the city does not address challenges of urbanisation and urban poverty, instead it undermines the social networks created by residents of informal settlements as their survival strategies, causes higher transportation costs and perpetuates social exclusion (Tshikotshi, 2009).

It was recognised that this housing subsidy strategy was only dedicated for developments on vacant land, which presented a policy gap in terms of the availability of subsidy system designed to facilitate in situ upgrading of informal settlements. To fill this policy gap, during the same year as BNG was launched; the Upgrading of Informal Settlements Programme (UISP) was introduced as Chapter 13 of the National Housing Code. Five years later, UISP was incorporated into Part 3 of the new Housing Code (Huchzermeyer et al, 2014). Not only was this move viewed as closing the policy gap, it was an act of acknowledgement that informal settlements are a part of cities and have the potential to solve the housing backlog for the urban poor, while preserving livelihoods (Wekesa et al., 2011). However, implementation of UISP was delayed at the provincial and local government level until 2008 when the NDH established a National Upgrading Support Programme (NUSP) which was incorporated in the UISP. NUSP's main task is to promote and support the implementation of the UISP in terms of co-ordination with sectors and partners involved as means to ensure that government's capacity and professional practitioners are strengthened to implement community-based incremental upgrading, mainly in the metropolitan cities (NUSP, 2015). NUSP was established to largely assist UISP in achieving Outcome 8 'Human Settlements' - upgrading of 400,000 households in informal settlements by 2014 (Huchzermeyer, 2014). UISP had a pilot project in all nine provinces, many of which intend to implement in situ upgrading throughout the province (Ziblim, 2013). Upgrading Informal Settlement Programme consists of four fundamental phases, namely; (1) application, (2) project initiation, (3) project implementation and (4) housing consolidation (Huchzermeyer, 2006). UISP recognises that the poor are attracted to particular locations due to the economic opportunities such locations

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

have to offer. Therefore, living in informal settlements is a survival strategy. Within these informal settlements, residents develop strong social networks which are considered their coping strategies. These include access to credit from community groups and the ability to create self-employment opportunities that have a strong customer-seller network and community-based mutual help and support (Braathen et al., 2014). UISP is set out to achieve effective informal settlement upgrading through ensuring minimal disruption to livelihoods, encourage community empowerment and community participation in decision-making (Huchzermeyer, 2006 and 2009). Informal settlement interventions that are not accessible to beneficiaries will result in their displacement to housing options that offer affordability and, in many cases, these are new or existing informal settlements, irrespective of the inclusiveness of the initial allocation procedure. Therefore, if skills development was not possible during the UISP implementation phases, then community-based or area-based subsidy mechanisms must be considered.

Like any other state housing programme, UISP is funded by government subsidy which caters for land rehabilitation, incremental provision of basic services, infrastructure provision and the last phase of the UISP process which is the housing project and sometimes health and educational facilities, recreational centres and shopping centres. While national government is liable for establishment of a funding framework for housing development, negotiating and securing funding allocation from the state budget for housing. Provincial government is there to support and strengthen the capacity of municipalities to facilitate housing provision including assessing funding applications received from municipalities, administer national housing programmes and monitor the performance of accredited municipalities. This leaves the local municipality with the responsibility to facilitate the development and management of housing stock as per their Integrated Development Plan (IDP) as well as identifying suitable vacant land for relocation (NUSP, 2015). The first step towards upgrading an informal settlement through UISP process requires feasibility investigation by the local municipality. When the location is proclaimed suitable for re-development and assumed that relocation is inevitable for community members in some cases, application for funding must consider both in situ upgrading and the relocation site (Huchzermeyer, 2009).

UISP principles and approaches apply also to relocation site and this is done to minimise the additional stress that comes with relocation. Nikuze et al. (2019) observed that there are worse socio-economic impacts associated with awaiting relocation, which is beyond the physical relocation, yet these are not given enough attention. Securing of livelihoods before relocation takes place helps concerned individuals to become more resilient and enable them to cope with post- relocation. Huchzermeyer (2009) highligted that UISP in situ upgrading is a positive response to many court cases of housing rights violation and forceful evictions that have been reported since 2000.

4 RESEARCH METHODOLOGY

The study is set out to explore the effectiveness of in situ upgrading in improving the quality of life of beneficiaries, studying Slovo Park informal settlement. The study area was chosen because it is one of the oldest informal settlements in Johannesburg and recently received a favourable court ruling to have the settlement upgraded through the UISP. Although there are no recent statistics on the total population of Slovo Park and the number of migrants in and out of the settlement, in 2011 the area was indicated to constitute of a total of more than 5 000 individuals, about 1 600 shacks amongst the 1 050 stands. The informal settlement was formed in 1994 and has since been expanding. The study applied a qualitative method, in which in-depth interviews and field observation were conducted. The combination of the two different data collection styles was proven to increase the standards of validity or to strengthen the credibility of research findings as compared to the use of a single data collection style (Salkind ed., 2010). The target population is the residents of Slovo Park informal settlement, particularly individuals older than 20 years preferably the elders within the families. The sample consist of participants who have lived experience of the subject matter, as such, are more likely to provide reliable and valid information. The sample was representative of the entire inhabitants of Slovo Park as it also included participants who are renting a shack and those who were allocated a stand in all genders. In order to understand the phenomena under investigation in the perspective of the participants, the researcher employed a semi-structured interview approach.

Interviews were conducted with ten (10) residents of Slovo Park. Although the sample size it relatively small, the selection was purposive and saturation was reached. Interview questions were written in English but the interviewees were interviewed in the participants‘ preferred language, which was mostly Southern Sesotho and IsiZulu. This is because the researcher avoided compromising the quality of the response. Thus, in order to preserve high quality in the answers provided by participants, the researcher allowed the participants to answer in their home language. Within 24 hours of the interview sessions, the recorded interviews were translated into English by the researcher and a written text of each interview was created. Through the transcribed interviews, the researcher established several themes that emerged consistently. Interviews were also conducted with two (2) of the City of Johannesburg (CoJ) municipal officials as facilitators (the Project Officer and Deputy Director for Housing Department) of UISP in the study area. For anonymity, participants’ names are disguised in the write up. The following themes guide data collection and analysis:

(a) Regulation of informal settlement

(b) Community Empowerment

(c) Safety within the community

(d) Improved livelihoods

(e) Improved food security

(f) Ineffective community participation in planning UISP

(g) Overcrowding

(h) UISP, a prolonged programme

5 A PERSPECTIVE ON THE UPGRADING INFORMAL SETTLEMENT PROGRAMME

This paper is providing details of views emerging from interviews and the literature, with an emphasis on the impact of UISP in improving the quality of life of informal settlements. This section is organised into two sub-sections, namely; success factors and limitations of UISP.

5.1 Success factors of UISP

5.1.1 Regulating of informal settlement

For the purpose of this paper, a stand can be described as a plot of land occupied by a household for residential purposes. During the interviews with residents of Slovo Park, the stand owners indicated that the high court’s verdict to have Slovo Park upgraded meant that the informal settlement is finally being regularised. Therefore, they will no longer live in constant fear of being evicted. Although stand numbers are changed every ten years, these numbers are reallocated to the existing owners and this has been providing the confidence in property ownership. This was indicated by the respondents in the interviews who said that “government will never evict us after investing so much money into electricity installations. Although stand numbers change every 10 years, I am not threatened because all these numbers are allocated to the same ID number…" Respondent 1. “I have a stand number that reassures me that I will not be relocated. Even if they change these numbers every 10 years, no one can claim my stand. In the yard, I have an electricity cable connected only to my house, as such, rentals are not a threat because it is clear to them too that the stand belongs to me. If I had financial resources, I would build a formal housing structure just like some of the community members who have already started”. Respondent 2.

From these views, it appears that residents of Slovo Park informal settlement are certain that regularisation of the settlement was achieved through the UISP process and that has reassured the residents that they will not be forcefully evicted from the area. As such, the in situ upgrading process was effective in instilling the confidence that residents have a secure place to live and this was achieved by installing electricity cables into each shack with a stand number. According to Amos (2011), the definition of informal settlements has been realised mainly based on their illegal or unpermitted occupation of land. The fear of illegal eviction and demolition has contributed to the likeliness of residents of informal settlements to build their shelters using building materials that are easy to remove, such as corrugated iron. Thus, regulating the settlement has impacted the residents positively because it implies that the settlement forms part of a planned area and it unblocks assets accumulation for the residents as they will be able to invest in their properties in compliance with the city’s acceptable building standard and norms. Tenure regularisation also promotes provision of urban services which were previously absent (Arimah & Branch, 2011). This also forms part of what Wekesa et al. (2011) indicated as the state's acknowledgement that informal settlements are not only a part of the cities but a potential solution to the existing state housing backlog.

5.1.2 Community Empowerment

Interviews revealed that some of community members were empowered during the electrification project, through the offering of temporary employment. It was highlighted that there were no initial intentions to employ community members on the project, which also delayed implementation processes. The decision to employ unemployed members of the community, accompanied by a fair selection process coordinated by the councillor ensured a successful implementation. These were views expressed by Respondent 3, who explained that "the Councilor facilitated the employment of unemployed community members. He applied a process called "fuduwa" meaning that individuals would put their names into a container which is shaken, and names are randomly picked. Even people living with disabilities were employed in the project".

From the above, residents from informal settlement expected upgrading projects not only to facilitate provision of services but also to provide employment, even if it is temporary. El Menshawy et al. (2011) indicated that an informal settlement intervention strategy must empower its beneficiaries through transforming their livelihoods. Therefore, community participation should go beyond decision-making and involve the community during the implementation stage. Simone et al. (2005) observed how this translate to public ownership and accountability necessary for the success of the project implemented for the beneficiaries. Furthermore, community capacity building (both leadership skills and technical knowledge) is realised. By achieving this, the UISP process achieved a successful community participation. According to Wekesa et al. (2011), UISP is one of the few progressive approaches that seeks to contribute towards social inclusion and economic empowerment of the urban poor.

5.1.3 Safety within the community

Residents indicated that, since the decision to upgrade Slovo Park in 2016 by the high court, the community got electrification in 2018. Electricity cables and metres were installed into the stand owner's shack and those who rent share with the stand owners. It was also observed that there are streetlights installed on each street. Residents expressed that this has contributed to the safety of the community. It was revealed during interviews with the residents of Slovo Park that quality of life has improved since the electrification project. Firstly, shack fires have reduced immensely. Secondly, health related issues contributed by paraffin gas have ceased. Thirdly, people no longer wake up too early to prepare for work, therefore, have extended resting period since they walk to work. Fourthly, food security has improved because households are able to buy food in bulk and store in refrigerators, which saves money in a long run. Lastly, the degree of crime has declined because streetlights have brought safety within the community. These were views expressed by the following participants, who indicated that"the quality of life has improved intensively between the time we were relying on illegal connections and now. I have changed from using a paraffin stove and a wooden stove to cook and heat water to bath in the morning, preparing for work" Respondent 3. "Access to electricity has simplified my life and I no longer fear for the safety of my children. When I leave my children for work in the morning or for a night shift, I am comfortable even if I were to forget the lights on" Respondent 2."Having access to electricity has eliminated the health issues I previously had when using a paraffin stove, which released gas that affected my lungs and eyes. With electricity, I can simply use an electric kettle and a 2-plate stove to prepare meals and heating bathing water. This saves me a lot of time. Through the light provided by the streetlights, we can monitor and ensure safety within the community" Respondent 4. "…I can buy food in bulk and store in the fridge. I have a monthly budget. In the morning, I can work up a little later than I used to to prepare for work. I no longer rely on 'mbaula' to warm up water, so, it saves me plenty of time. The streetlights installed have provided safety within the community as we are able to see everything that is happening on our streets at night. So, this has reduced the crime rate. I am also safe walking on the street in the early hours going to work" Respondent 5.

Individuals in the study have a view about their quality of life and their interpretation of the concept is accepted. Based on the above views, it is evident that residents are satisfied with the social infrastructure improvements meant to improve their quality of life. According to Amao (2012), there are three main philosophical approaches to determine the quality of life. The first philosophical approach is the normative ideals and belief systems that individuals live by. This describes the personal experience of people. The second philosophical approach describes the satisfaction citizens attain from obtaining the things they desire.

The third philosophical approach encompasses the first and second approach, therefore description of quality of life, factors such as feelings of joy, pleasure, contentment, and life satisfaction based on personal experience. According to Tonon (2015), when qualitative methodology is applied in a quality of life study, it becomes imperative to consider people´s perceptions, opinions, feelings, ideas and interpretations. This approach is important to help the researcher understand people's experiences of wellbeing and issues related to quality of life. This is because the study of the quality of life has a direct link to the material conditions such as the social welfare and to the psycho-social conditions such as the personal welfare.

5.1.4 Improved food security

It was also indicated during interviews that since the electrification, residents not only are able to save money on monthly groceries but also have improved food security. These were comments made by respondents, who said "…having access to electricity has reduced the amount of money I spent on basic food. I can buy food in bulk and store in the fridge" Respondent 6."Access to electricity improved food security in the household and helps me stick to the monthly grocery budget. Having to constantly buy meat, at times rotten because vendors also used ice to keep the meat fresh and this made it very hard for me to save money towards other needs. When I go to work, I know that my children have access to good food during the day because, as you may know a shack is very hot, so when we leave cooked meals in the pots, the food gets rotten and difficult to eat" Respondent 1.

From these views, it is undeniable that socioeconomic status has a direct link to food security. Residents of informal settlements are generally low-income earners, which has implications on the diet or type of food they can afford to buy to sustain them for a month. Lack of access to electricity worsens the circumstance of food insecurity because buying food such as milk and frozen meat in bulk is not an option. Yet, this could reduce the cost of food on a monthly basis as compared to buying single items on a day to day basis. According to Naicker et al. (2015), residents of informal settlements face a much higher level of food insecurity due to very low income and lack of full-time employment. This contributes to undernutrition or malnutrition because some of the coping strategies employed during food insecurity include decreasing of the variety of foods eaten. As such, consumption of vegetables, fruit and protein would decrease. Although household income did not improve amongst the residents of Slovo Park, having access to electricity helped households save the little money they earn by enhancing the opportunity to buy food in bulk due to better storage capacity. This also had a direct impact on food security.

5.1.5 Improved livelihoods

A resident who relies on income generated through rentals indicated that access to electricity has enhanced their livelihoods. Even the Project Officer from CoJ highlighted that "those with rental business have dramatically increased their fees after electricity installation" Respondent 12. However, the landlord expressed her concerns that the upgrading might have negative effects on their livelihoods. For example, relocation of rentals will limit the demand and provision of housing might mean they can no longer have shacks rented in the yards. This was a view stated by Respondent 2, who indicated that "I mainly rely on the income I get from the rentals. If the upgrading, for example, housing provision would mean I can no longer accommodate rented shacks, then this upgrading will have a negative impact on my livelihood".

The above statement indicates that stand owners benefiting from rentals would prefer not to be disadvantaged by the upgrading, especially during the housing provision. Once again, it is evident that the community of Slovo Park bought into UISP without fully understanding what it entails and this is a concern. Relocation of some of the community members is inevitable in many cases of in situ informal settlement upgrading. This is mainly to reduce overcrowding in informal settlements and avoid using unsuitable areas within the settlement. However, Huchzemeyer (2006) highlighted that the UISP process considers the socio-economic viability indicators that will trace the households' livelihood strategies. UISP intends to respond flexibly to demand, rather than simply allocating the same product equitably to all households within a community or every informal settlement.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

5.2 Limitations of UISP

5.2.1 Ineffective community participation in planning UISP

It was discovered from the interviews that the community was frequently invited to an information session hosted by the Slovo Park Community Development Forum (SPCDF). During these meetings, different opinions were shared but not necessarily considered. The aim of these meetings was to share information on the plans derived for the upgrading and provide progress report. Respondent 7, who is also a committee member in the SPCDF, expressed the following when he was asked if he perceived community as actively involved in the planning of the in situ upgrading programme. “Yes, under the guidance of SERI who also helped us with the court case against the City of Johannesburg”. While the following respondents’ views to the same question were as follows: “the committee in representation of the community was actively involved. I would not say the community was passively involved” Respondent 5. “Not directly, the community was frequently invited to meetings which were basically information sessions regarding the upcoming implementations” Respondent 1. The municipal official indicated that “all inputs, audio recorded and/or written were taken into consideration when developing layout draft mindful of geotechnical, and environmental impact assessment advice” Respondent 12.“…but community participation was limited to the SERI, Centre for Urbanism & Built Environment Studies (CUBES) and the Slovo Park committee. The ward councillor including the Community Development Workers (CDW) were not participating. My view is that individual residents must be afford an opportunity to come up with the intervention such as reclamation facilities without necessarily being led by a team, which in my view do not necessarily share their interests” Respondent 11. “…beneficiary education of prescripts of the UISP policy is critical so that the community can buy into a programme they understand holistically, and this is something the municipal officials are not satisfied that it was fully conducted” Respondent 12.

Community participation is a crucial aspect of the UISP process, in fact, it is what distinguishes UISP from all other housing strategies under the umbrella of the NUSP. Failure to facilitate this important stage of the UISP process has the potential to create community’s misunderstanding and conflict during implementation. Although a community may elect representatives, it is important that the representatives share the same ideas as the community. This helps eliminate resistance or failure to comply with the regulations of the products received from the upgrading programme. It also helps ensure that the products provided are suitable to the needs of the community. Conducting a real community participation would require committees representing beneficiaries to become involved at all levels from strategy level down to project implementation level. El Menshawy et al. (2011), also indicated that real community participation is essential. Wekesa et al. (2011) also emphasised that the physical planning aspect of the process should not be concluded at the top level, but should be based on the inputs derived from public participation in order for the end product to be accessible and affordable to the real end-users.

5.2.2 UISP, a prolonged programme

During an interview, Respondent 12 indicated that:

“Quality of lives among dwellers improve as delivery of constitutionally rights services is effected. The provision of water, toilets, electricity, and other amenities improve lives…”. “It has to be noted that this is 100% government subsidised programme, so full implementation of upgrading can take 10 years depending on population of occupants; land rights; suitability of ground in terms of habitability; and availability of funds from coffers to attend to each activities of every phase. Other factors which may derail completion is migration of residents” Respondent 12. Yet the respondents indicated that: “If this was not a prolonged process, it could be effective and efficient. We have tolerated bad living conditions for more than 2 decades in Slovo Park, therefore the incremental development process undermines the urgency of basic services. I would suggest that the duration intended to complete this programme be reduced to a shorter period so that our children can have a better future. We are no longer thinking of ourselves but our children” Respondent 1. “….Government should source out funds to simultaneously provide most of the basic services. This development will take a long time to be completed and most of us might not be alive to see most of the services. For example, our leaders, Mohau and Mampara passed on without witnessing/enjoying the fruit of their tireless efforts” Respondent 4.

These perceptions indicate that UISP has shortcomings in improving the quality of life of beneficiaries living in informal settlements and this is due to the lengthy period of completing a comprehensive UISP. Funding has been highlighted as a factor that delays implementation completion as this is a 100% government funded programme. However, these delays contribute to other factors which will further delay completion of an effective UISP process that would improve the quality of life of beneficiaries living in informal settlements. This includes migration of residents into the settlement. According to Amirah et al. (2011) city authorities have been unable to manage rapid urbanisation which resulted in the development of informal settlements. This has mainly been due to lack of financial and technical capacity. El Menshawy et al. (2011) also indicated that informal settlements upgrading is often avoided because it requires a large financial input to make provision of the entire infrastructure systems. As such upgrading stages would spread the costs over a longer period. According to Huchzermeyer (2006), municipalities apply for UISP funding which provides a one-off project funding of land rehabilitation. Beyond this, the relevant municipality is responsible for bulk infrastructure and maintenance of services post-implementation. This must fall under an approved municipal IDP which implies that products/projects will be provided on the priority and funds availability basis.

Interviewee responses		Overview
5.1 Success factors of UISP	• Regulating of informal settlement	Social networks are maintained, and livelihoods are uninterrupted. Stand numbers are allocated and electricity cables are installed to each shack, particularly the stand owner’s shack.
	• Community Empowerment	Electrification project offered temporary employment to residents. It is also acknowledged that UISP still require the establishment of Community Builder Programme.
	• Safety within the community	Crime rate is reduced within the settlement due to the provided public lights.
	• Improved livelihoods	Stand owners increased rental fees subsequent to the electrification project.
	• Improved food security	Households are able to buy food in bulk and store in the refrigerator for the month.
5.2 Limitations of UISP	• Ineffective community participation in planning UISP	Indirect community participation resulted in the physical planning aspect of the process unknown to the beneficiaries. Thus, residents are unable to upgrade top structure. Affordability of the provided services presents a potential threat to the success of UISP. Poor socio-economies could result in the displacement of the beneficiaries.
	• Overcrowding	Excess rentals contribute to insufficiency of services provided by UISP, i.e. reliability of electricity.
	• UISP, a prolonged programme	A minimum of 10 years to complete UISP process is too long and opens opportunities of overcrowding.

Table 1: Overview of interview responses

5.2.3 Overcrowding

Participant in the interviews were concerned about excess rentals in Slovo Park and indicated that they contribute to the unreliability of electricity. Each stand has more than three shacks and this overloads the transformers, thus, power-cuts are frequent while the city responds to power delays. When asked to point out contributors that lead to the failure of the plans of in situ upgrading to focus on improving the quality of life in Slovo Park, respondents pointed out that “implementation of an informal settlement upgrading is a long and delayed process. Even people that did not live here initially, move here due to the attraction that the

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

initiated implementation brings, which in my view will hinder the success of the plan. The community is growing despite some families moving to other places. The identified land is already getting occupied by people that were not initially earmarked for that land" Respondent 7."So far, this plan is unsuccessful because we still have excessive rentals and overcrowding which makes the provided services insufficient…. Government has the powers to identify suitable land and do relocations. The sooner this is done the sooner the effectiveness of this upgrading will be satisfactory. At the moment, although we have access to electricity we are overcrowded, as such this electricity is unreliable because the population exceeds the electricity capacity, thus the transformer bursts frequently. It is clear that the same will happen with all the other services government intends to provide for us" Respondent 8. It was also discovered during an interview with a renting participant that simultaneously, she feels disadvantaged by the delays in implementing the relocation phase. In her view, the in situ upgrading implemented in Slovo Park, which she also fought for will not benefit her because she does not have tenure security. Respondent 3 expressed these views by saying that "I am yet to be relocated. So, I cannot say I have security of tenure".

Poor planning of in situ upgrading has compromised the efforts of improving quality of life of beneficiaries' post-implementation because access to electricity is unreliable in the Slovo Park informal settlement due to overcrowding. Not only that, individuals identified for relocation are not made aware of the details of implementation. According to Nikuze, et al. (2019), application for UISP funding should cater for both in situ upgrading and the relocation site. The local municipality has the responsibility to identify suitable vacant land for relocation. UISP principles and approaches apply also to the relocation site and this is done to minimise the additional stress that comes with relocation. Institutional incapacity in terms of financial and technical resources are compromising the effectiveness of UISP in improving the quality of life of beneficiaries living in informal settlements.

6 CONCLUSION AND RECOMMENDATIONS

The existence of informal settlements in urban areas has been perceived as a result of ineffective housing policy, insufficiency of housing finance, unequipped public utilities and local municipalities to create tenure security to the ever-growing population in cities. Eradication of informal settlements in a form of relocation has been prominent in South Africa, especially through the BNG projects, in which qualifying households are provided with low-cost housing and basic services on an identified suitable site. This strategy has been criticised for its disregard for the impact it has on livelihoods and social networks critical for survival of the residents. ISUP is considered a "progressive informal settlement eradication vehicle" designed under the NUSP as it seeks to respond flexibly to housing demand and move beyond providing low-income housing in the peripheries of the city. Thus, integrating informal settlements into the larger fabric of the city, both geographically and socially. This paper reveals that in situ upgrading programme has regularised the settlement by officially allocating stand numbers and securing land tenure as the first step towards improving the quality of life of the residents of Slovo Park. As such, UISP has had a positive impact because it acknowledges the community's social networks by introducing minimal interruption to their current livelihoods while waiting for incremental upgrading implementation. CoJ officials confirm that the Slovo Park informal settlement is on course to ultimately be an approved settlement for township establishment and then to have a project subsidy number for permanent purposes.

The paper reveals that residents of Slovo Park are content with access to electricity because some componenta of their quality of life have improved since the installation of electricity within the community. These include the improved safety due to public lights installed, the use of electric appliances such as stoves to prepare meals and kettles for heating water to wash which have reduced health issues related to the previous use of paraffin stoves. The convenience of using electricity for preparing for work has added more time for resting. The likelihood of shack fires has declined drastically, and food security has improved because there are opportunities to buy food in bulk and store in the refrigerator. For stand owner's, access to electricity opened an opportunity for rental fee increase, which has made a significant improvement to their livelihoods.

Considering the above, various recommendations can be delineated including the following:

(1) that in situ upgrading is complementary to the community's socio-economic status. UISP should consider the socio-economic circumstance of the community. This paper reveals that Slovo Park has excessive rentals, and this is because rentals are a source of income to supplement low-income earners and in the case of

retired individuals, rentals are the main source of income. Therefore, if the plan is to eradicate informality, UISP should incorporate formal structures for rental in addition to housing to allow continuous access to this income. This way, the provided infrastructure will match the expected number of people in a community. If not, households will continue perpetuation of renting shacks, which will defeat the purpose of the in situ upgrading programme. The aspect of community participation plays a significant role in this. Top-down planning and implementation process allowing for little or no input from beneficiary communities should be avoided because they result in community resistance to possessing a sense of responsibility to ensure compliance with the city's regulations.

(2) That UISP addresses overcrowding as the first step. It is recommendable that every informal settlement upgrading begins with addressing overcrowding. This will ensure that services provided are adequate and reliable. This paper reveals that there is a concern that Slovo Park will remain overcrowded for a long time because individuals previously identified for relocation have not been relocated to the identified suitable site. Yet, other people are migrating to that site. If most people cannot be accommodated on the identified vacant and suitable land, they will remain in the community, overstretching the resources provided for the reduced population of Slovo Park. This will defeat the purpose of the upgrading process because the quality of life of residents of Slovo Park will remain unchanged. Therefore, if relocation of some of the residents was recommended, it is advisable that this is executed before basic services are provided. This will help with monitoring and discouraging migration into the settlement.

(3) That UISP facilitates community empowerment for the sustainability of the upgrading. The paper reveals that there is an expectation from the community that local development must involve the local community by means of job creation even if it is a temporary offer. Nonetheless, this is also an important aspect of the community participation process, it is as significant as the in situ upgrading planning process. An informal settlement such as Slovo Park has a high unemployment rate and an unskilled population. As such, they can only offer labour resources during a project and temporarily enhance their livelihoods. The challenge with this is that post-implementation, the livelihood circumstance of this community members remains unchanged. This is a factor identified by the CoJ municipal officials which recommended the need for an improved procurement processes that will cater for local needs in terms of introducing a delivery vehicle that will promote a Community Builder Programme. It is assumed that this would empower the community and enhance their skills. Community empowerment would not only enhance the livelihoods of the residents of this informal settlement but would also ensure sustainability of the provided services. This would be a significant effort toward improving the quality of life of residents of informal settlements.

7 LIMITATIONS OF THE STUDY

Most of the residents of Slovo Park informal settlement do not understand the English language fluently. As such, the researcher had to translate interview questions from English to either IsiZulu or Southern Sesotho during the interview in order to accommodate the interviewee. This limitation contributed to time consuming task of translation of all transcripts to English. Fixing of appointments with the relevant municipal officials proved to be another limitation to the study. The researcher had to postpone the interview because municipal officials were unavailable on dates or times previously arranged. Additionally, the research had limitation by methodology, as such further study can be conducted using quantitative approach, with a larger sample and in other informal settlements to get a broader view of the topic.

Energy Issues in Building and District Assessment Schemes and Benchmarking Systems

Matthias Haase

(Prof. Dr. Matthias Haase, ZHAW, Am Gruental, Waedenswil, Switzerland, Matthias.haase@zhaw.ch)

1 ABSTRACT

In the Canton of Zurich an increasing number of customers in their business area for building energy solutions have been identified who have their properties certified with sustainability systems. They have to create regular reports or use benchmarks to optimise their properties with regard to energetic aspects.

A large amount of detailed information is available on the use and differences of rating and certification systems. For stakeholders in the energy market sector, however, it is important to have the necessary information available on energy monitoring data and GHG (greenhouse gas) emission reporting for value creation. One promising concept is the 2000-Watt-Area.

A 2000-Watt-Area (200WA) is a new form of settlement. It has achieved a reputation for energy efficiency, renewable energies and climate friendliness and reflects the values of a responsible society.

In this work we try to find answers to the following questions:

- Which evaluation criteria are the basis for the 2000WA?
- How much can these urban areas lower their GHG emissions?
- What role do the instruments of energy efficiency and renewable energies play in this?
- What is the relationship between these and what statements can be made with regard to mobility?
- How can the Facility Manager help to transform successfully into 2000WA?

The paper is based on literature research and three interviews with stakeholders in the Swiss construction sector (a district representative, an energy consultant, a technology provider). The findings qualify the concept of 2000WA and put it into a wider international context of certification and benchmarking systems.

It was found that 39 2000WA are in operation, implementation and transition in Switzerland. From the experience gained from these districts it can be seen that the 2000WA concept is trying to include important aspects of a sustainable transition of districts. While many districts were new developments (34), only 5 were districts in transformation. The number of districts in transformation need to increase considerably if the GHG emission reduction goals in Switzerland are to be met. Facility managers can play an important role in this transition. But they need to enhance their skills and responsibilities in order to fulfil their roles as transition managers. Evaluating the 2000WA can be a key to this and has the potential to enhance the reduction of GHG emissions in districts and cities.

Keywords: 2000-Watt-Site, benchmarking system, certification system, energy monitoring data, greenhouse gas emissions

2 INTRODUCTION

2.1 Renovation and transformation

Climate change challenge the ambitious goals that regulators have put in place by setting more and more aggressive building and community energy-related requirements based on the Sustainable Development Goals of the UN. The concept of Energy Master Planning (EMP) can help to initiate a better planning and implementation process to fulfil these goals. In the EU, reaching for the climate gas reduction goals of the Paris Agreement, stakeholders on all geographical and organisational levels from nations, regions, cities and communities are challenged. Following bottom-up approaches for energy planning on the neighbourhood level is a promising attempt to reduce energy demand, increase energy efficiency and lower the carbon footprint in a multi-stakeholder approach.

In the context of the 2012 EU directive (EED 2012), several important measures have been adopted throughout the EU to improve energy efficiency. These include national long-term renovation strategies for the building stock in each EU country, mandatory energy efficiency certificates accompanying the sale and rental of buildings, the preparation of national energy efficiency action plans (NEEAPs) every three years, minimum energy efficiency standards and labelling for a variety of products, as well as obligation schemes for energy companies to achieve yearly energy savings of 1.5% of annual sales to final consumers. However, Member States have yet to fully implement the Directive and additional support in building capacity and know-how is needed (EPBD 2018). Significant additional energy savings, reduced emissions, and increased energy security can be realised by considering holistic solutions for the heating, cooling and power needs of communities, on neighbourhood and district scale, comprising collections of buildings. As a result, considerable literature has become available including both guidance and assessment tools aimed at EMP at the neighbourhood and district level as e.g. campuses (DOE 2013; Huang et al. 2015; EnergyPlan 2019; BREEAM 2019; DGNB 2018). But the existing guidance and tools do not seem to be fully solving the challenges. The energy planning consists in determining the optimal mix of energy sources to satisfy a given energy demand. The major difficulties of this issue lie in its multi scales aspect (temporal and geographical), but also in the necessity to consider the quantitative (economic, technical) but also qualitative (environmental impact, social) criteria (Schiefelbein et al. 2017).

In order to be able to apply principles of a holistic approach to neighbourhood and districts, often coined community energy planning in the literature, and to provide the necessary methods and instruments to master planners, decision makers, and stakeholders, it is essential to identify and frame the constraints that bound the options towards an optimised energy master planning solution (Haase and Lohse 2019). Existing master planning guidance available indicates that identifying and establishing project goals is a critical first step (Jank, 2017).

In a new initiative of the European Commission, Positive Energy Districts are envisioned as "are energy-efficient and energy-flexible urban areas or groups of connected buildings which produce net zero greenhouse gas emissions and actively manage an annual local or regional surplus production of renewable energy. They require integration of different systems and infrastructures and interaction between buildings, the users and the regional energy, mobility and ICT systems, while securing the energy supply and a good life for all in line with social, economic and environmental sustainability." (JPI UE 2020).

In many cities, the necessary legal and strategic frameworks for the realisation of PED/PENs are not yet in place. Very often, there is also a lack of a planning culture in city administrations or the personnel resources available might be insufficient. In particular, the transformation of large (brownfield) areas to climate neutral city districts has a big potential for the development of PED/PENs but needs cooperation between administration, industry, and research. Especially in case of heterogeneous ownership structures, cooperative planning processes are indispensable. Far less common in EMP guidance and related literature is information on the identification of constraints that limit energy technology options and how stakeholders influence the decision-making process. Literature in this area mentions options analysis or prioritization, or optimization analysis (EED 2012; Jank, 2017; Fox 2016; Zhivov et al. 2014; Robinson et al. 2009), yet, options analysis or optimisation is clearly influenced by project energy-related constraints. Sharp et al. (2020) compared EMP in several countries and analysed these constraints (Sharp et al. 20120). The results show that successful energy master planning is highly dependent on a thorough understanding of framing goals and constraints, both local and regional, and their associated limitations that will dictate the optimum master planning design. Haase and Baer (2021) pointed out that as more and more countries push to improve energy efficiency, environmental impact, and the resilience of their buildings and neighbourhoods, the need for early and comprehensive energy master planning on neighbourhood and district level is critically important. In addition, certification schemes could help to enhance the improvement of our cities and districts.

Therefore, it was interesting to explore what has been developed in Switzerland (Energie Schweiz). In particular, the concept of the 2000-Watt society seems a valuable contribution to the discussion of further implementation of PEDs.

2.2 2000-Watt-society

The 2000-Watt Society is a vision for a liveable future (2000-Watt-Society). People in such a society care for a high quality of life that meets the goals of sustainability. They appreciate the resources the earth provides, use them sensibly and share them equally around the globe. The 2000-Watt Society gathers interested people who know that quality of life is not inextricably tied to a constantly higher material standard of living. This vision is based on the view that a future society should represent a sustainable and socially just society. For every person on earth, 2000 W of continuous power (primary energy) are available. This must be enough to ensure prosperity and a high quality of life. Today, the primary energy consumption per capita worldwide is on average 2500 W – with enormous country-specific differences. At present, each Swiss inhabitant uses about 4700 W. The CO2 emissions caused by this level of energy consumption must not exceed 1 tonne per person per year (2000-Watt-Society).

Thus, drastic climate change can be actively counteracted. The goals of the 2000-Watt Society are scheduled to be met between the years 2050-2100. A rescheduling of these goals towards 2040-2050 is currently under development. One tool to achieve this vision in by the introduction of a certification scheme, 2000-Watt-Sites. This certification scheme is in place since 2008 and thus some experiences could be gained already.

2.3 2000-Watt-Sites

The development of districts requires a distinct understanding of the situation now as well as a vision of the future district to be able to develop suitable pathways for this transition. In order to be able to do that a district needs to be modelled that consists of several buildings, sufficiently described so that the future district can actively manage their energy consumption and the energy flow between them and the wider energy system. The energy master planning process requires an analysis of different scenarios, which include new construction to different levels of energy efficiency, major renovation of all or some buildings comprising building stock under consideration with Deep Energy Retrofit of these buildings, minor renovations with energy-related scope of work, or demolition of some old buildings. Such analysis requires building energy modelling.

A 2000-Watt-Site (200WS) is a new form of settlement (2000-Watt-Areal, 2000-Watt Areal in transition). It has achieved a reputation for energy efficiency, renewable energies and climate friendliness and reflects the values of a responsible society. The core idea of the 2000-Watt Site is an ongoing evaluation process of a site's sustainability in terms of energy in development, planning, implementation and operation. Certificates are issued for a limited time period and must be renewed periodically. They are awarded in two stages: As a «site under development» until at least half of the total living space is in use, and after that as a «site in operation» (2000-Watt society, 2000-Watt Areal in transition).

The 2000-Watt Site certificate creates added value for all stakeholders – for investors, planners, users, law enforcement agencies and authorities: users enjoy a high standard of housing and living. They can live with the assurance that they are contributing to resource conservation and climate protection. Investors and owners are interested in value-preserving sites offering a high quality of living and working. The quality characteristics are useful for marketing and image-building. Due to the high level of acceptance, cooperation with authorities is much easier. It helps local municipalities to bring their concerns to bear at an early stage. The certificate is a guarantee of successful commercial implementation of their energy and climate-policy goals.

2.3.1 Criteria used in 2000-Watt-Sites

The subject areas of the criteria for evaluation of 2000-Watt-Sites are shown in Table 1. In the management system subject area a maximum of 110 points is possible, followed by the subject area site utilisation and urban planning with 100 points. In the subject areas buildings and mobility 90 points can be achieved, while in the subject areas communication, cooperation, participation an supply and waste disposal a maximum of 70 points can be achieved.

Subject area	**Max. pts.**
1. Management system	110
2. Communication, cooperation, participation	70
3. Site utilization and urban planning	100
4. Supply and waste disposal	70
5. Buildings	90
6. Mobility	90
Site total	530

Table 1: Subject areas of the 2000-Watt-Sites.

2.3.2 Research question

In this work we try to find answers to the following questions:

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

- Which evaluation criteria are the basis for the 2000WS?
- How much can these urban areas lower their GHG emissions?
- What role do the instruments of energy efficiency and renewable energies play in this?
- What is the relationship between these and what statements can be made with regard to mobility?
- How can the Facility Manager help to transform successfully into 2000WS?

3 METHODS

The paper is based on literature research and three interviews with stakeholders in the Swiss construction sector (a district representative, an energy consultant, a technology provider). The findings qualify the concept of 2000WS and put it into a wider international context of certification and benchmarking systems.

3.1 Literature review

There are several publications about 2000-W-Society and 2000-W-Sites available (2000-Watt-Society; Energiestadt 2021a, Energiestadt 2021b, Energiestadt 2021c). However, most of the literature is in German only. The 2000-Watt-Society published a number of documents that are downloadable from their website.

The programme “Energieforschung Stadt Zürich» (energy research of the city of Zurich) has conducted extensive accommodated research of all 2000-Watt-Sites that were realised in the city of Zurich in the past 15 years. Energy Research City of Zurich was a ten-year programme and focused on topics at the interface between social science research and the application of new or existing efficiency technologies, which are particularly interesting in an urban context. Focus was put on application-oriented research for more energy efficiency and renewable energies (Stadt Zurich, Stadt Zurich and ewz, SIA380). The research results and findings are generally publicly available and are available to all interested parties so that the City of Zurich Energy Research has the greatest possible impact - also outside the city of Zurich. Research has being carried out in two subject areas.

The topic of households started with the residents of the city of Zurich, who consume energy at home, at work and on the go and, as decision-makers, play a central role in the implementation of the 2000-Watt society in many respects. In particular, social science aspects that promote or prevent conscious use of energy were examined. In field trials with households in the city of Zurich, it has been investigated which obstacles in the city of Zurich are relevant in everyday life and which measures are used to overcome them.

The topic of buildings started with the building infrastructure, which is responsible for around 70 percent of the final energy consumption in the city of Zurich (Stadt Zurich). In scientifically designed and accompanied implementation projects, renovation strategies for buildings were developed and implemented together with the owners and other decision-makers in order to make a significant contribution to the renovation and renewal of the building fabric in the city of Zurich (Stadt Zurich). The focus was put on increasing energy efficiency in the heating sector and minimising electricity consumption. In addition, there exist a number of certification schemes in Switzerland (NNBS 2018), including the system of the Swiss Council for Sustainable Building (SGNI).

3.2 Interviews

The first interview was conducted in March 2021 a district representative near Winterthur, in the North of Zurich. The district consists of 51 living units in 8 row houses. The whole district was constructed in the 1970s and is due for retrofitting. The energy supply system was due for renewal a couple of years ago and in 2018 the oil boiler was renewed. This was a lost opportunity for a comprehensive energy retrofit and the interview was focusing on the process, the incentives and professional support from industry.

The second interview was conducted in April 2021 with an energy consultant in the south of Zurich.

The third interview was conducted in May 2021 with a technology provider from a Swiss certification body. The interview was focusing on the tools and incentives in the Swiss market. The certification that forms the basis for the 2000WS was critically discussed with the interviewee.

4 RESULTS

It was found that 39 2000WS are in operation, implementation and transition in Switzerland. From the experience gained from these districts it can be seen that the 2000WS concept is trying to include important aspects of a sustainable transition of districts. While many districts were new developments (34), seven of these sites are in operation, while additional five districts were in transformation.

4.1 In operation and transformation

Table 1 summarises the 2000WS which are in operation or in transformation. A total area of 101265526m2 is covered, certification was registered between 2017 and 2021. The areas can be found in Bern, Lenzburg, Zurich, Chur, Winterthur, Oberkirch (LU) and Lausanne.

4.2 Evaluation criteria

A certification is an affirmation or a marketing strategy that companies, cooperatives, property owners or organisations adhere to specified standards or guidelines. Certification for a 2000-Watt-Site is carried out by independent certification bodies using a catalogue of criteria that must be met. The opinions and arguments for certifying or not certifying the area differ depending on the building owner. For sustainable companies, certification is a demonstration of their pioneering role. For cities, municipalities, universities and other training facilities, the role model role is completely at the centre. For settlements, certification brings further advantages, such as a certificate represents a high-quality development for the public and the community and higher rent can be charged. As fossil energies will become more expensive in the future, renewable energies and buildings will be subsidised depending on the location of the municipality or canton.

Buildings and areas can be certified after commissioning. The qualitative and quantitative requirements must simply be met and the evidence must be available. With the recertification, the quality assurance processes are periodically checked for the target direction of the area level and if so needs to be adapted to the latest development. Recertification is open to anyone interested in the new 2000-Watt area in transformation. Three sites are reported here in more detail as they were recently recertified as depicted in Table 3.

Rezertifiziert 2021

Table 3: Three example sites from Zurich

4.2.1 Hunziker area in Zurich, certified in 2017

Since 2015, the cooperative has been offering more than living space for 1200 people and 150 workplaces in the north of Zurich. Several housing cooperatives joined forces and in 2007 founded the cooperative “more than living”. They had the idea of living together and to adopt new structural innovations. In 2010, “more than living” took over the 41000m2 Hunziker area - once a concrete factory that was getting on in years - from the city of Zurich under construction law. In the articles of association of the cooperative it was noted that the principles of the 2000 Watt society are practiced and lived in. The value of 30kWh / m2 according to Minergie-P specifications is adhered to throughout the area. The waste heat is used for heating the entire area monitored by the neighbouring city data centre. The cooperative covers 20 percent of the electricity consumption via the photovoltaic systems on the roofs. The buildings are very striking due to their diversity, which were built by five architectural teams as part of the overall urban planning concept.

A total of 13 buildings were built. The Hunziker Areal is their first pioneering work of a holistic understanding of sustainability. The cooperative provides answers to new, changed housing needs and sustainable social change.

The Hunziker area was built for a long-term living cycle with various constructions and the latest building technology. For the 370 residential units, the area offers various typologies for different needs and budgets. A wide variety of offers, e.g. from studios to cluster apartments with larger communal areas enable a high mix of residents. There are occupancy regulations in the cooperative and residents do not have a private car. In the area, people live actively with one another instead of an anonymous neighbourhood. This principle means that numerous common ground floor uses and open spaces are available to residents for free use. There they celebrate together, plant vegetables and run their own workshop. Since the area was strictly planned and later also built according to the sustainability criteria of the 2000 Watt Society, the area achieved very good values in the certification. The area is one of a total of five pilot areas that were the first to receive the label for the operation phase and are allowed to pass it on. 2000-Watt area offers living perspectives with development potential for tried and tested and new forms of living. With the incentive to be able to combine several things, such as living, working, attractive business and participation processes, and the diversity of living realities, a social, sustainable and lively quarter was created. Thanks to the sustainable, energy-saving building, the consistent use of renewable energies and innovative technologies, many resources are saved in everyday life. Above all, giving up one's own car is exemplified. This shows that it works and that the goals of the 2000 Watt society can be met. A three-year research monitoring project was successfully developed to optimise the operating values and checked with the financial help of the Swiss Federal Office of Energy (SFOE 2008).

Briefly summarised it is the vision of the cooperative to continue to adhere to the goals of the 2000 Watt society. Building energy-efficient buildings, using the latest technologies and few cars or hybrid cars support an environmentally friendly lifestyle and save valuable resources. The “more than living” cooperative attaches great importance to high-quality architecture, good quality in construction and sustainability in the maintenance of the buildings.

4.2.2 Kalkbreite in Zurich, certified in 2017

The Kalkbreite Cooperative fulfils all the necessary Minergie-P-Eco-Bau requirements in terms of energy and ecology. The building only needs a little added heat, which is generated by means of a groundwater heat pump. 15% of the electricity required is produced by the company's own photovoltaic system on the roof. Although the buildings are equipped according to Minergie-P-Eco and have a healthy ecological construction method, they have to reveal the built-in grey energy. During construction there is a need for grey energy (SIA 2032).

The building can only achieve optimal energy savings when it is in operation. They depend on how the heating is used in the apartments, how often the residents ventilate and whether the lights are left on unnecessarily. Depending on this, the hot water also plays a major role, as it has to be heated up with energy first. Mobility is classified as the second largest energy consumer in our society. Mobility needs are very individual and it is difficult to influence them with sustainability, since everyone drives what they want. Kalkbreite has taken a number of measures to enable residents to use their mobility in a more sustainable manner. Charging stations have been set up for electric cars, which are charged by the photovoltaic system on the roof.

In the Kalkbreite area, the average space consumption per person, including the share of shared space, is 33.5m2. This land consumption is much lower in the cooperative than in new buildings, where it is 45m2 or more per capita. Since the Kalkbreite has large building parts of 16.5m and complex corner situations, due to the location, larger apartments were created during construction which made it difficult to achieve the objectives. The heating consumes less energy than the hot water preparation. The hot water is produced with heat pumps and stored in storage tanks on each stairwell. No solar panels are needed for hot water preparation. The electricity is generated with the photovoltaic system and covers around 20% of consumption.

The heating is operated sustainably and environmentally friendly and set to a comfort temperature of a maximum of 20 degrees in living and sleeping rooms. The bathrooms are heated to 21 degrees with an outside temperature of -8 degrees. Five times less energy is used in Kalkbreite than in an average house or ten times less than in an unrenovated house built between 1960 and 1980.

That is why the usage behaviour of the residents is decisive for achieving the savings potential. Incorrect ventilation can cause apartments to cool down. Then it needs energy again to reach the normal living temperature. When the sun is shining in summer and winter, residents have to use the sun protection correctly, otherwise the apartments may overheat. Since the rooms are very well insulated, the sun can heat the rooms strongly and dissipate excess heat poorly. In summer it is important to use the shading intelligently.

The Kalkbreite Cooperative has built in comfort ventilation, which ensures a constant, low exchange of air with filtered outside air. The heat exchanger extracts heat from the exhaust air and preheats the supply air. With this comfort ventilation, residents can sleep at night with the window closed without any problems and, if necessary, open and close the windows manually. Several data such as electricity, warm, cold water, heating and waste are measured in the Kalkbreite and clearly shown in the utility bill. This means that residents can see their consumption and thus motivate them to reduce it for the next year.

In order to maintain living comfort, a glass collection point was even set up within a few walking meters. The City of Zurich will provide additional waste collection points.

Those at the desk and carrying out housekeeping are at the heart of the Kalkbreite Cooperative. They serve several purposes, such as the reception for guests of the pension and tenants of the flex rooms and are also available as a contact person for various matters of the residents and commercial tenants. On the ground floor of the building there is a bicycle parking lot, which is equipped with a practical bicycle parking space, as well as a bar and a large tram hall of the Zurich public transport organisation (ZVV). In addition, the Kalkbreite Cooperative offers a subsidised youth apartment for shared apartments for young people from 16 to 25 years of age. The cooperative is very committed to a healthy mix of families and, above all, to sustainability for the sake of the environment.

4.2.3 Sihlbogen in Zurich, recertified in 2021

With the Sihlbogen development, the Zurlinden building cooperative has created a lively centre in Zurich Leimbach. Due to the proximity of the city and nature, this area offers a high quality of living and great access to public transport. The Sihlbogen consists of three buildings on two construction sites. The two residential buildings on site B were completed in 2013 and offer car-free living. The residential and commercial development on site A was completed in 2015. Site A takes on the role of a new district centre and offers several shopping opportunities and services.

The settlement includes 220 units, which consist of family and old people's homes and studio apartments and create a good mix, which contributes to a pleasant atmosphere in the area. The three buildings were designed to be compact, resulting in low resource consumption during construction and operation.

In site A, a conventional solid construction method was used, while in site B a load-bearing structure made of wood was used. The heat is generated through several sustainable channels: pellet heating, biogas heating, air-water heat pumps and the use of waste heat. Photovoltaic panels were set up on the roofs to produce electricity for their own use. The Sihlbogen location has excellent public transport connections. As a resident, one can live well without an own car. Since the residents of site B do not have their own car, they receive a Rail-Check voucher for public transport. The 2000 Watt society relies on car sharing. Two mobility cars and one rental electric car are available on the Sihlbogen area. The residents can use a self-produced app to communicate, which supports active social coexistence.

Since the beginning, the Sihlbogen development has been planned and built according to the goals of the 2000WS. In 2015, the Sihlbogen received the 2000WS in development certificate and was later duly certified in 2017. Before recertification in 2021, the cooperative received the 2000WS in operation certificate. As in Kalkbreite, the Sihlbogen was a pioneering project in sustainable construction and commissioning.

The Zurlinden building cooperative has been committed to sustainable building for more than 10 years. The strategy of the cooperative is based on the 2000 Watt society. The SIA norm 2040 is the most important instrument for the implementation. The architecture competition was based on the specification as early as 2015. Building an object according to the 2000WS means thinking holistically and, in addition to operation and grey energy, also considering mobility (according to SIA norm 2039), waste management and building technology.

In today's construction market, innovation is in demand, new building products are being researched and developed. Sustainable, environmentally friendly criteria such as system separation, interchangeability, life cycle costs, renewable raw materials and short delivery routes are in the foreground. With renewable energy, the energy costs are minimal, so that investment costs pay off over time. In this cooperative, a ZVV subscription is also included in the rental price to encourage the use of public transport.

subject area	Hunziker Areal		Kalkbreite		Sihlbogen	
1. Management system	83	75%	92	84%	107	97%
2. Communication, cooperation, participation	70	100%	70	100%	56	80%
3. Site utilisation and urban planning	100	100%	84	84%	88	88%
4. Supply and waste disposal	53	76%	60	86%	62	89%
5. Buildings	88	98%	76	84%	76	84%
6. Mobility	88	98%	90	100%	85	94%
Site total	482	91%	472	89%	474	89%

Table 4: Distribution of points in the three example sites

Table 4 summarises the results from the 2000WS certification and shows the distribution of points that each of the three example sites have achieved. The percentage of achievement, which must exceed 67% (according to the certification rules) has been achieved in all 2000WS (see also Table 2). Please note, that maximum achievable points differ for the different subject areas (as shown in Figure 1). All three example sites achieved 91% (Hunziker Areal), 89% respectively (Kalkbreite and Sihlbogen). The Hunziker Areal achieved 100% in two subject areas (communication, cooperation, participation and site utilisation and urban planning). Kalbreite achieved 100% in two subject areas (communication, cooperation, participation and mobility).

Detail	Hunziker Areal	Kalkbreite	Sihlbogen
Type of use	mixed use	mixed use	mixed use
Energy standard	Minergie-P-ECO	Minergie-P-ECO	SIA 2040
Heat production	District heating system with server waste heat from the city data centre (heating and hot water)	Ground source heat pumps	pellets, heat pump, biogas, waste heat
Cold production	electricity	free cooling (ground water)	industry cold for large distributer
Electricity	-	PV, eco power tariff	PV, swiss electricity mix

Table 5: Energy supply details of three example sites

Table 5 shows the details of the energy supply of the different example sites. All sites build upon the efficient building energy standard which minimises energy demand. For heat and cold production, different systems are in use (heating solutions ranging from connection to district heating with utilisation of waste heat, GSHP, and pellets). Two sites have included PV systems on-site, which produce 15% (Sihlbogen) and 20% (Kalkbreite) of the energy need on-site.

In various cantons there are general restrictions on the use of new instruments in the energy sector or restrictions on instruments that move away from energetic building regulations in the direction of operating permits. In these cases, an additional tightening of the cantonal area regulations at the communal level is not permitted. The scope for action for new energy requirements must therefore be clarified on a canton-specific basis. At the municipal level, depending on the existing legal regulations, the legal basis for binding regulations must often first be created (successful examples exist. Additional agreements between the municipality and the site authority are always possible).

Three distinct advantages could be shown:

(1) Proof of 2000-Watt compatibility: As part of the building application, the compatibility of the 2000WS with the goals of the 2000 Watt society is demonstrated.

(2) Mobility concept: A mobility concept shows how systematic mobility management should be set up and operated in planning and implementation.

(3) Monitoring / Controlling: Monitoring in the operating phase allows the municipality to gather its own experience with the real behaviour of the buildings and their users. Current practice ranges between a “monitoring light” (only for operating energy) and a more comprehensive monitoring / controlling concept for operating energy and the mobility caused by a site.

5 CONCLUSION

The number of districts in transformation need to increase considerably if the GHG emission reduction goals in Switzerland are to be met. It was found that 39 2000WA are in operation, implementation and transition in Switzerland. From the experience gained from these districts it can be seen that the 2000WA concept is trying to include important aspects of a sustainable transition of districts. While many districts were new developments (34), only 5 were districts in transformation. The number of districts in transformation need to increase considerably if the GHG emission reduction goals in Switzerland are to be met.

The proof of the concept and the need for monitoring and controlling results are demonstrated on sites where they are implemented and operate as planned. This is an important factor for the further replication of the concept. In many cities, the necessary legal and strategic frameworks for the realisation of PED/PENs are not yet in place. Very often, there is also a lack of a planning culture in city administrations or the personnel resources available might be insufficient. In particular, the transformation of large (brownfield) areas to climate neutral city districts has a big potential for the development of PED/PENs but needs cooperation between administration, industry, and research. 2000WS can help to enhance the transition and decarbonise our cities and districts. There are several stakeholders that can play an important role in this transition. Facility managers can play an important role in this transition. But they need to enhance their skills and responsibilities in order to fulfil their roles as transition managers. Evaluating the 2000WA can be a key to this and has the potential to enhance the reduction of GHG emissions in districts and cities.

1 ABSTRACT

Each city or an urban space has a unique identity and a character of its own. Therefore, there is a special pleasure in looking at a city and its components. The lived experience added to a place is considered significant to people through time. Think of a city and directly its streets come to your mind, according to Jacobs (1961). People experience the city through moving in a linear path formed by elements, such as; building façades, trees, curbs, and other elements. Streetscape skeleton, along with other physical design elements, form the vista that any individual recognises when arriving at an urban place or a street. Due to the dynamic development of cities, a key question concerning the quality of life is always asked. According to the World Health Organisation (WHO) the standard indicators of the quality of life is physical and mental health, and social belonging. This paper aims to identify the most important physical features in streetscape design elements according to users, as well as showing which of the physical features could enhance identity and character of a place. Literature reviews and the analysis of a case study in downtown Alexandria in Egypt are used as the research methodology and procedures for this paper. The results show a hierarchical ranking of elements to take into consideration to design a future guideline or a framework to enhance the identity of a street or an urban space. Findings show that the Physical Setting is the most noticeable quality of place to users. It is also clear that the Softscape elements are considered the most important when answering the question of the important physical features with the largest impact on identity and sense of comfort.

Keywords: Streetscape, Character, Urban Design, Identity, History

2 INTRODUCTION

When Kevin Lynch (1960) explained the five elements of a city, i.e. landmark, path, node, district, and edge, he stated that the path is the most important element. IN 1961, Jane Jacobs said in “The Death and Life of Great American Cities” that “Streets and their sidewalks, the main public places of a city, are its most vital organs. Think of a city and what comes to mind? Its streets. If the city’s streets look interesting, the city looks interesting; if they look dull, the city looks dull”. Scholars suggest that streets are used as social spaces rather than just movement channels. Universal design principles of streetscape elements may bring streetscapes to become more user-friendly, sustainable, and functional.

As people use urban places in their daily life, they are affected by the experience. This lived experience is affected by various dimensions, such as morphological, perceptual, social, visual, functional, and temporal dimensions (Carmona et al., 2010). The elements that contribute to these dimensions are the streetscape elements and their composition. That is why the design of streetscape can determine the people’s perception of the city’s identity and character (Wibisono, 2001). Unlike squares that need something, an object or an event, to keep people coming, streets are necessary urban spaces (Gehl, 1987).

The case study chosen is characterised by its remarkable history and significant buildings, which create the identity of the place. The unique location of Alexandria has made it an attraction to various civilisations ever since the Ptolemy times. This has caused Alexandria to become the window to the cultures and arts from European countries. Ever since Muhammed Ali and his family allowed for interactions with foreign colonies, Alexandria has witnessed its own renaissance during the second half of the nineteenth century, resulting in a city with a unique character. However, in the past century, Alexandria has witnessed a rapid change due to globalisation and urbanisation. This change was clearly uncontrolled, causing deterioration of the existing conditions of heritage spaces as a result of general cultural ignorance, lack of maintenance and regulations, and natural conditions. These factors directly impacted the urban environment and hindered the preservation of its historic part (Getty, 2009).

Historic Urban Landscapes (HUL) have received more attention after the United Nations Educational, Scientific and Cultural Organization (UNESCO) recommendations in 2001 aimed at protecting historic urban settings from deterioration and fragmentation resulting from uncontrolled urban development (Bandarin, 2015). Governments and cultural heritage organisations appreciate the importance of preserving diverse physical cultural heritage through various ways. The question that remains is whether they understand the importance of cultural memory and whether they take account of social identity in their plan in order not to affect the human psyche negatively.

3 THE METHOD

Interactive and comparative methods of research are used to explore the dimensions of the paper. Two-phases of data collection have been employed. The first phase is the literature review on identity, its components and principles and its relation with streetscape design and elements. The second phase are surveys conducted both on-site and online. The on-site survey was aimed at static users; those who have constant contact with the place such as shop owners, vendors and residents, and the online surveys aimed at mobile users; those who are considered visitors and shoppers. The survey questions aimed to identify the importance of the case study in terms of memory and identity, as well as the important physical streetscape features. The qualitative data resulting from the surveys will show the important physical attributes in streetscape design that enhance identity and character.

4 IDENTITY

4.1 Place and Space

The terms "space" and "place" tend to be used interchangeably. However, after being better defined the two terms represent separate concepts, interacting in a dynamic relationship. According to the English Longman Dictionary (2001), place is defined as "any area, place, position or status in space" and "a point, particularly within a wider area". It defines space as "the amount of an area available to be used". Specific to an architectural aspect, spaces are conceived as abstract geometries explained in terms of distance, direction, shape, size, and volume, detached from material form and cultural interpretation (Gieryn, 2000).

According to Edward Relph (1976), in order to change a space to become a place, meanings, individuals, groups, or societies are added. Yi-Fu Tuan, a Chinese-American geographer and philosopher, said "Place is security, space is freedom: we are attached to the one and long for the other". Mumford (1961) wrote of the modern metropolis, that it is a place where individuals "are progressively reduced to a bundle of reflexes, without self-starting autonomous goals". In Proshansky's, "The city and self-identity" he defines place identity as "those dimensions of self that define the individual's personal identity in relation to the physical environment by means of a complex pattern of conscious and unconscious ideas, beliefs, preferences, feelings, values, goals, and behavioural tendencies and skills relevant to this environment". All these views argue along the same axis, that eventually a space is a part of the creation of a place. Space is considered a blank slate that is yet to be coloured with personal experience to add meaning and memory.

4.2 Urban Identity

Identity is a subjective feeling of self-sameness and continuity over time in different places and social situations (Kroger, 2000). Identity implies the distinction from other things and the recognition as a separate entity. It is not in the sense of equality with something else, rather the individuality and oneness. Identity serves as the base for recognition. In parallel, Lynch (1981) also defines identity as "the extent to which a person can recognise or recall a place as being distinct from other places". Goldsteen and Elliot (1994) assert that "the word identity has distinctive advantages in terms of open spaces, streets, and spaces between buildings because it encompasses the notion of a specific location and the unique relationship between the place and its context". Identity in an urban environment is to a greater or lesser degree defined by the environment's elements and activities or events taking place within that environment (Cheshmehzangi and Heath, 2012; Zakariya and Harun, 2013). According to Kevin Lynch (1960), "an environmental image may be analysed into three components: identity, structure, and meaning". These three components work together to present a workable image.

Due to rapid urbanisation, industrialisation, and commoditisation of place, placelessness lies deep in globalisation that generates standardised and inauthentic urban landscapes (Arefi, 1999). In this regard, Relph (1976) describes placelessness as "an environment without significant places and the underlying attitude which does not acknowledge the significance in places". This phenomenon affects the identity of many local urban places. The loss of meaning in a place results in the inability to continue to feel, to practice and to recall experiences (Hull et al., 1994). This loss could be the result of change or transformation of spaces or buildings, or the changes of uses and functions, or other reasons. However, it is eventually resulting in a feeling of detachment, thus weakening the place attachment, therefore; loss of identity. Researchers argue that the incapability of the modernist approach in facing the contemporary issues, including the deterioration of historic or unique streets and spaces, will lead to disintegrated self or group identity (Salama, 2009). Therefore, there needs to be an approach to conceive places contextually and understand the complexities of what gives places their identities.

4.3 Components of place

The concept of place is physical as well as psychological. Theorists, such as Canter (1977), Edward Relph (1976), Montgomery (1998), and Falahat (2006) have stated the three components of place, as shown in Fig. 1. They each classified the components into three categories differing in naming but with the same meaning. The three components are; physical setting, activities, and meaning. The physical setting is the real physical being of the place. It consists of the buildings, landscape, and the aesthetic quality. The physical setting influences the symbolic meaning of the landscape. The activity component is the events that take place in any space that respectively results in the experience of the user. The meaning is the resulted outcome based on the human interaction with the place or the activity. Place attachment is embedded in the feeling, emotion, and behaviour reflected by people from interactions. These three components do not effectively exist individually, but rather the wholeness of their complex interaction helps define the identity and character of a place.

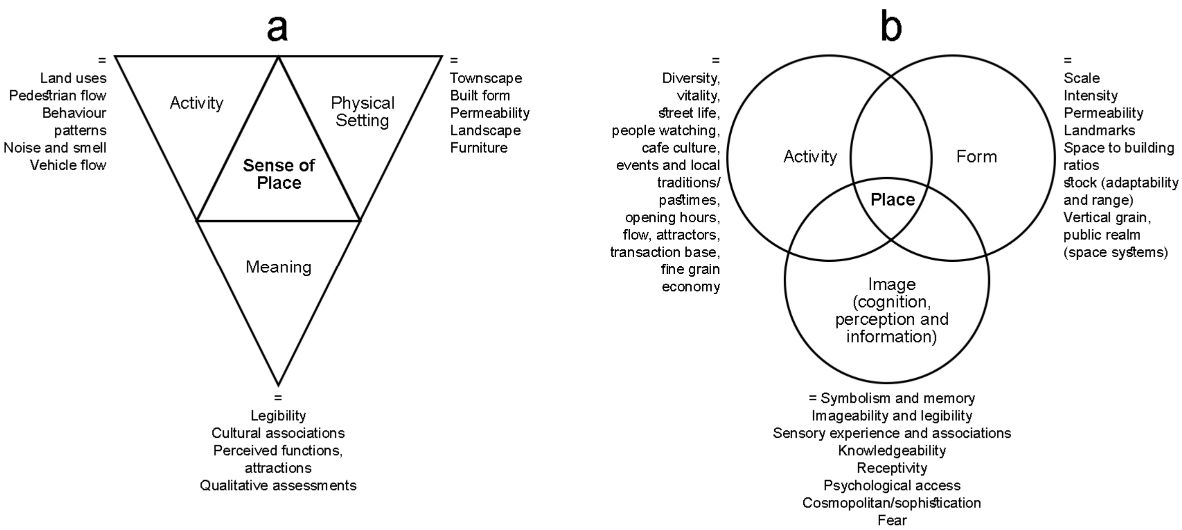

Fig. 1: Components of Place suggested by (a) Punter (1991), and (b) Montgomery (1998), adapted from Carmona et al. (2010)

It is important to note that a place could not be separated from people who invest meanings in them, as stated by Soja (1996) and quoted in Gieryn (2000), "places are also interpreted, narrated, perceived, felt, understood, and imagined". Meeting the biological, mental, and social needs of a human, the physical setting will be the result of a series of perceptions, satisfaction, and finally a sense of place (Falahat, 2006). Places are dynamic and will continue to regenerate as people struggle to adapt to new meanings that might detach them from their culture and identity.

The loss of the sense of place, or the identity of the place, will result in affecting people's perception and attachment to places. It is recommended by researchers that in order to capture the meaning of a place, the physical setting, the activity, and the sense of place should be complementarily taken into account (Agnew and Duncan, 1989). Therefore, it is clear that assessing the significance of people's psychological connections with places eventually results in the assessment of place quality.

4.4 Qualities of Place (Principles of Identity)

The identity of a place is enhanced by five main qualities, or principles, stated by theorists, such as Breakwell (1986), Twigger-Ross and Uzzell (1996) and later added on by Lalli (1992) and Vignoles (2006),

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

as shown in Table 1. These qualities are: distinctiveness, continuity, significance, compatibility, and cohesiveness. These qualities can either strengthen or weaken the identity of a place. They are also called principles of identity of place. The purpose of these qualities, or principles, is to show the relation between places and the way people identify with them.

<table>
<tr><th>Theorists</th><th>Qualities of place</th></tr>
<tr><td>Breakwell (1986)</td><td rowspan="2">Distinctiveness
Continuity
Significance (self-esteem)
Compatibility (self-efficacy)</td></tr>
<tr><td>Twigger-Ross and Uzzell (1996)</td></tr>
<tr><td>Lalli (1992)</td><td rowspan="2">Cohesiveness (rootedness)</td></tr>
<tr><td>Vignoles (2006)</td></tr>
</table>

Table 1: Qualities of place according to various theorists (by author)

The first four principles were identified by Breakwell (1986) and later on modified by Twigger-Ross and Uzzell (1996) and Lalli (1992). The first principle, distinctiveness, explains the uniqueness in the relation that a person has with his/her environment distinct from any other relationship. Research by Feldman and Hummon (1990) focused on settlement identity as the distinctiveness associated with being a 'city', 'town', or 'country' person. This distinctiveness associates the lifestyle with the place to create a memory. Lalli (1992) discussed that specific place identification is that "the bond to a particular part of town also contributes to one's differentiation from residents in other town areas". This explains that place identifications can be a great contributor to the distinctiveness principle.

The second principle, continuity, refers to the long-term relationship between people and place created by their life experience over time. There are two types of continuity; place-referent continuity and place-congruent continuity. Place-referent continuity is explained by various theorists as when the place acts as the referent to past selves and actions and that for some people, maintenance of a link with the place provides a sense of continuity to their identity. This is "maintained by fixing aids for memory in the environment ... creating coherence and continuity in one's self-conceptions" (Korpela, 1989). Therefore, place-referent continuity refers to the maintenance of continuity via specific places that have emotional significance. On the other hand, place-congruent continuity differs from place-referent continuity in terms of specificity. It refers to the maintenance of continuity via characteristics of places which are generic and transferable from one place to another. People will choose an environment that manifests the values that they highly esteem and personified of objectified in their objects of identification (Graumann, 1983).

The third principle, significance, also referred to as self-esteem by Twigger-Ross and Uzzell, shows "the positive evaluation identified concerning a person's feeling of worth or social value" (Twigger-Ross and Uzzell, 1996). There is a significant difference between evaluation and the feeling of self-esteem itself. If, for example, a person says "I like the Docklands", this is called evaluation. On the other hand, saying that "living in the Docklands makes me feel good about myself", this is called self-esteem (Twigger-Ross and Uzzell, 1996). There is also a clear evidence of positive self-esteem through association with a prestigious place (Lalli, 1992). The two are related; however, an evaluation may affect the person positively, but not convey the same positiveness on a person's self-esteem.

The forth principle, compatibility, also referred to as self-efficacy by Twigger-Ross and Uzzell, shows that the environment has the capabilities to meet individuals' demands. Self-efficacy is "regarded as high when the individual believes he/she can perform an act or complete a task", as explained by Twigger-Ross and Uzzell. This results in creating a manageable environment where residents can develop a predictive system that allows them to judge whether a setting supports their goals and purposes (Winkel, 1981).

The fifth principle, cohesiveness, also referred to rootedness by Lalli, refers to maintaining a sense of intimacy, homogeneity, and compactness in the built environment. It's also emphasised by the emotional ties or the personal belonging developed by an emotional connections. This principle strengthens attachment which results in reinforcing personal identity of place.

In conclusion, the principles of identity have clarified the meanings and role emotionally salient places have on a person's identity. Thus, suggesting that identity process has a dynamic relationship with the residents' built environment. Breakwell's (1986) identity process theory was designed to examine threats to identity; showing that there is a clear link between identity and the physical environment.

5 STREETSCAPE

Streetscape is a distinct component of street design and it must receive separate planning and design attention. Streetscapes are the three-dimensional outdoor spaces that surround roadways and are outlined by buildings that form the "streetscape skeleton". The overall design of streetscape is affected by various design elements. However, the proportions and scale of streetscape skeletons are significant factors in affecting the comfort and productivity for users (Alexander et al., 1977; Cullen, 1971; Gehl, 2010; Jacobs, 1961).

Enclosure provides streetscape with a sense of spatial identity (Cullen, 1971). Enclosure helps intensify the feeling of negative space, thus the perception of the boundaries and components of the space itself. Enclosed spaces are perceived by users as safe-feeling and memorable, thus; an identity is linked to the space for the user. While enclosure speaks of proportions it does not account for scale. The terms "scale" and "human scale" are commonly used interchangeably. However in urban design literature, there are definitive interpretations of the boundaries of human scale (Alexander et al., 1977). Scale is conveyed by furniture, planters, ornaments, or even by the size of surrounding structures and spaces. Theorists also discuss that scale can be conveyed by the context of speed, given that a wide street may feel more appropriate when cars are in high speed (Ewing and Handy, 2009). On the other hand, human scale refers to the appealing scale for users on foot, or pedestrians. There are several interpretations of specific dimensions and limits of perception and social interaction prescribed by various theorists and authors to specify efficient design guidelines for the ideal feeling of human scale.

5.1 Streetscape Character

The character and design of streetscape are some of the determining factors in the success of highlighting the city's cultural identity (Pegler, 2006). Streetscape character is affected by design guidelines and design elements. That explains the approach of using streetscape as a focal urban aspect in many cities to invigorate places and enhance the sense of place with all the accompanied values and harmonies.

The appearance and relationship between the exterior features of a city and the design elements of the street determine the character (Wibisono, 2001). Streetscape spans from the façades of a building on one side to the other. According to Hartanti (2012), streetscape consists of three layers; vehicular lane, public frontage, and the private frontage, as shown in Fig. 2.

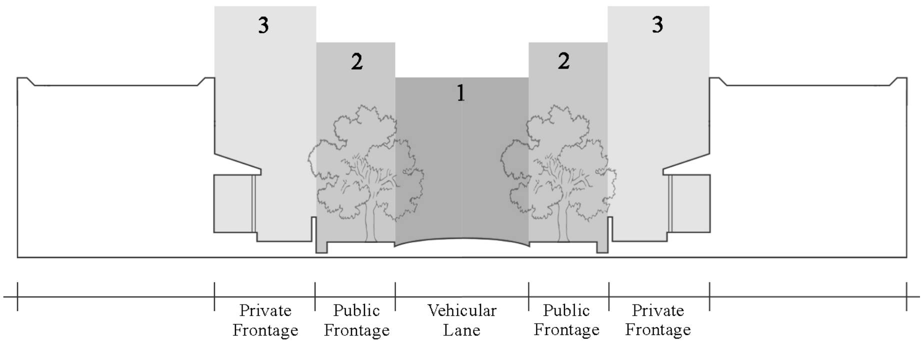

Fig. 2: Layers of streetscape according to Hartanti (2012), adapted by Aurbach (2005)

The private frontage is the privately owned land extending from the building façade to the plot boundary. That space may include arcades, porches, stoops, fences, yards, alleys and in-fill spaces, special activity spaces, and special event spaces. The public frontage is the publicly owned space extending from the private plot boundaries to the edge of the vehicular lane, and it is known as the roadside. That space includes sidewalks or pathways, street corners and curbs extensions, street planters, trees and other vegetation landscaping, and other street furniture as fixtures, seating, and utilities. The vehicular lanes are the spaces extending from curb to curb, or from pavement edges from one side to the other if there are no curbs. This space is used as thoroughfare including travel lanes and parking lanes.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

According to Mansouri and Natsumoto (2009), streetscape composition is divided into two systems; static system and dynamic system. The static system includes the buildings envelope, the street sky, openings, the road, urban furniture, and green infrastructure. The dynamic system includes the mechanical system, which is the vehicles, and the human system, which are people and creatures.

5.2 Streetscape Design Elements

Streetscape design elements - according to the Downtown Development Association of the City of Cheyenne in Wyoming and the Downtown Alliance of the Grand Rapids Neighbourhood in Michigan - are divided into sidewalks, street corners and curb extensions, trees and landscape strips, movable and fixed planters, seating, trash/ash receptacles, public art, screening, fencing, railings and walls, café spaces, special event spaces, alleys and in-fill spaces, fixtures or utility zones, utilities, and lighting. Streetscape design elements can be divided into four main categories: hardscape, softscape, furniture, and external influencers, as shown in Table 2. Buildings and trees may also be called streetscape skeletons, given that they are dominant objects according to their proportion and scale.

Main categories	Sub-categories
Hardscape	Sidewalks (pathways)
	Street corners and curb extensions
Softscape	Trees and landscape strips
	Planters (movable – fixed)
Furniture (fixtures)	Seating
	Trash/ash receptacles
	Signage
	Screening
	Fencing, railing, building façades and walls
	Fixtures and utility zones
	Utilities
	Lighting
External Influencers	Special activity spaces
	Special event spaces
	Alley and in-fill spaces
	Public art

Table 2: Categorization of streetscape design elements (by author)

6 CASE STUDY: ELMANSHEYA SQUARE IN ALEXANDRIA, EGYPT

6.1 Background of Alexandria

Alexandria is the second capital of Egypt and its major port. Due to its strategic location and rich lands, Alexandria has been a jewel amongst the Mediterranean cities. It features a fusion of communities; Greek, Italians, Armenians, Muslims, Christians, and Jews. Given that it is one of the oldest cities in the world, Alexandria holds a rich history and a piece of mystery around every corner. Ever since Muhammed Ali and his family allowed for interactions with foreign colonies, Alexandria has witnessed its own renaissance. During the second half of the 19th century, this renaissance resulted in a city with a unique character.

For the past few decades, due to urbanisation and globalisation, significant rapid change has taken place in Alexandria. The struggle between its symbolic Mediterranean significance, history, urban form, identity, and economic and political agendas and new cultural interventions is causing the historical districts to lose their identity and sense of connection to the past. This change, over time, was clearly uncontrolled, causing deterioration of the existing conditions of heritage spaces as a result of general cultural ignorance, lack of maintenance and regulations, and natural conditions. These factors directly impacted the urban environment and hindered the preservation of its historic part (Getty, 2009). As a result, certain historical features in old streets and urban plazas started to fade away, causing Alexandria to suffer from a loss of identity.

6.2 Background of ElMansheya Square

ElMansheya Square is located in the district of AlGomrok, part of the city centre. Over its history, this area had other names: Place d'Armes, Grand-Place, Place des Consuls, Place Mohamed Ali, and now Midan ElTahrir or "Liberation Square". During the 19th century, ElMansheya Square was considered the commercial centre of Alexandria. The commercial centre later moved eastward to Saad Zaghlul Square, where the Cecil and Metropole hotels are still located.

When the French expedition led by Bonaparte embarked in Alexandria in 1798, the area of ElMansheya was an open field. The military maps of this period mark an undefined open space as an "Esplanade", also known as a promenade (Awad, 1996). In 1814, the site was described by the British traveller Bramsen: "The large square near the sea is spacious; it has been improved and covered with gravel by the Europeans who came here to breathe the sea breezes". This confirms with Captain W. H. Smith's map of 1833 indicating the space as "parade gravée". During the second half of the 19th century, Ali Pasha Mubarak, an Egyptian public works and education minister, described the area as partly open vacant land, used by Bedouins. It was also called "Kom ElHallah" (Awad, 1996).

The square appears fully developed in Charles Muller's map of 1855, as shown in Fig. 3 to the left. The new Place des Consuls was developed by Mancini, who also designed most of the buildings surrounding the square. The surrounding rectangular buildings are three or four stories high residential buildings of an Italian-oriental aspect, similar to those of Italian cities such as the port of Trieste in the mid-18th century Austro-Hungarian Empire.

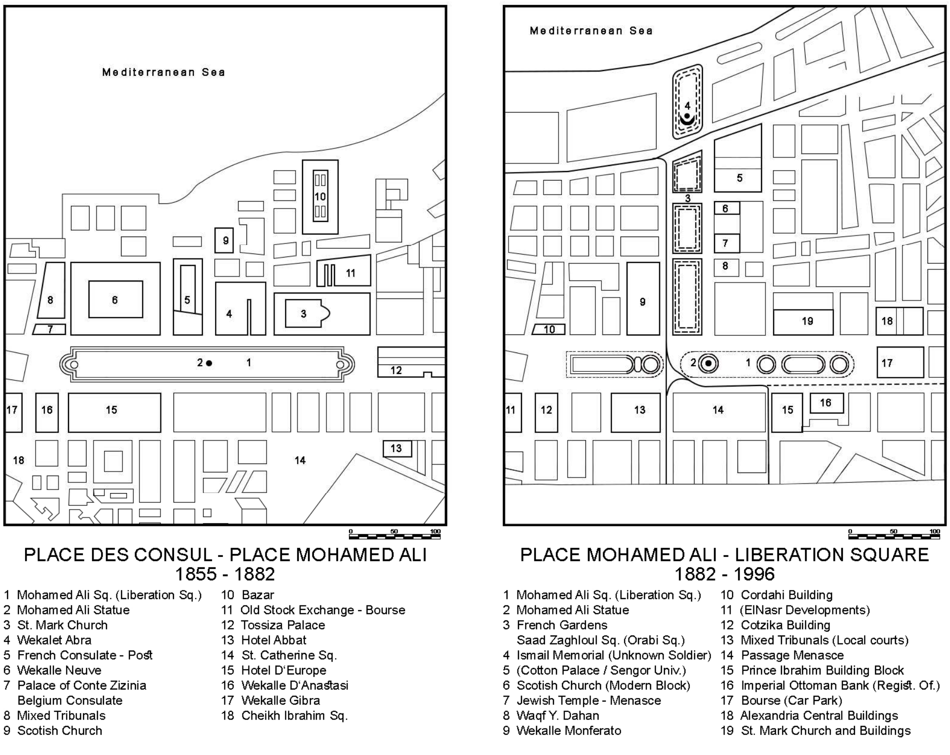

Fig. 3: Place Des Consul (left) by Charles Muller, and Place Mohamed Ali (right) by Mancini, adapted by Awad (1996)

6.3 French and Italian Influences

The Palace of M. Tossiza, the Greek Consul, was designed by Macini. It stood majestically on the Eastern location of the square, along with the elegant Palais of Count Zizinia, Belgium's acting Consul. The Place Des Consuls was dominated by commercial and business activities. They ranged from numerous large wakalas, which are buildings famous during the Islamic period that housed merchants and their goods serving as a centre for trade, storage and transactions, such as Gibra, D'Anastasi, and Neuve, with ground floors reserved for commercial enterprises and public services and the upper floors reserved for offices and residential use.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

In John Murray's "Handbook for Travellers in Egypt" in 1880, he mentioned that among these commercial enterprises were David Robertson and Co. Booksellers, Rocheman Jewellers, Boret the hairdresser, and photographers as Fiorillo, and general outfitters like Cordier. Also there were numerous cafés; such as the glamourous Le Café de France No27, hotels; such as Hotel d'Europe, and restaurants. Other businesses included insurance companies; such as Peel & Co., the Lebon Gas Co., and the Italian postal services and banks like the Anglo-Egyptian Banks.

The most noted building on the square was the French Consulate. Its gardens were open to the public on weekends and special occasions. In 1866, La Bourse building, for stock exchange, was created. The Tossiza Palace was used to house the new stock exchange building.

Some of the religious buildings included the Anglican church of Saint Mark, and located near the square were the Scottish church, the German and French Protestants, the Roman Catholic, the Greek Orthodox, the Maronite and Armenian churches, and ElCheikh Ibrahim mosque. The presence of Muslim, Coptic, and Jewish places of worship in proximity to one another affirms the multi-ethnic composition of the cosmopolitan city of Alexandria.

During the ruling of Khedive Ismail, a statue of Mohamed Ali was designed by the French sculptor, Jacquemart. The equestrian statue of the city's modern founder with its white carrara marble base, later designed by French architect Ambroise Baudry 1871-1873, stood as a landmark in the Mohamed Ali Square.

Place Mohamed Ali was targeted and destroyed by the bombardment of July 11th, 1882. Only two buildings survived of the destroyed square, namely the stock exchange and the Saint Mark church. A military tribunal was set up in front of the Tossiza Palace, called the Ismail Memorial or the "Unknown Soldier".

The rapid post-1882 development and government compensations resulted in a climate of political stability, sustained economic growth, and administrative reorganisation. A small group of notable family names controlled most financial activities in the city. These agents and bankers, who have become real estate promoters and main shareholders of development companies, were responsible for the development of a great part of ElMansheya, rue Sherif Pasha, and buildings on rue Rosette. They also created the Municipality of Alexandria in 1890, thus controlling the city's fate. This gave them the opportunity to further promote the European character of the city.

At the beginning of the 20th century, the Europeanisation of the urban morphology continued, creating a new urban space, La Place des Jardins Français in 1909. The Place des Jardins Français was enhanced by the elegant new French consulate in 1909 designed by the French Bureau of Public Works and led by the French architect Victor Erlanger. French influences seemed to have inspired the area and complemented the French garden landscape (Awad, 1996). The gardens were in the French style characterised by an ordered and symmetrical geometric plan. The French influence continued during the Post World War I period, and due to the increase in the price of cotton, Egyptian economy prospered and enriched the city's merchants.

In the 1960s, the gardens were completely removed and replaced by a bus station, making it one of the most crowded areas of the city. Then in the 1980s, a new plan was generated and the station was removed, turning it once more into a public square. However, the new design wasn't the original French Gardens, as shown in Fig. 4.

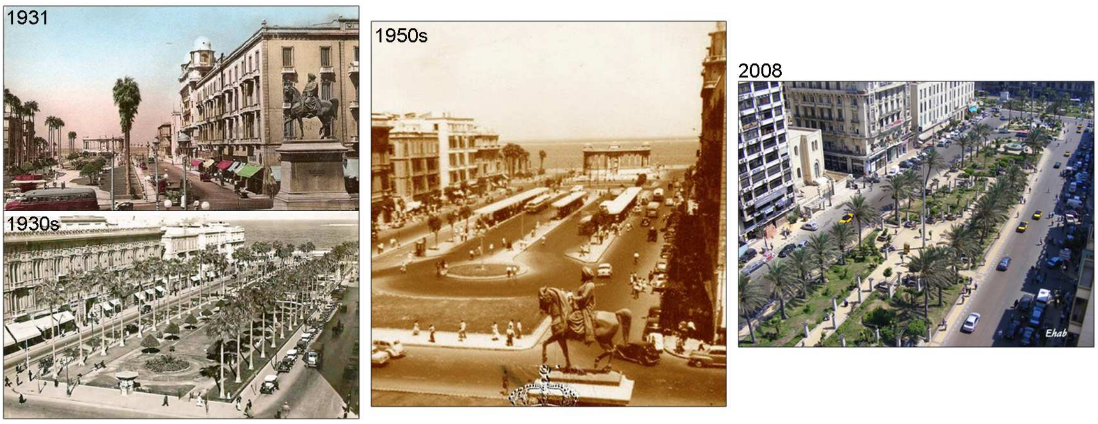

Fig. 4: Four photos of Oraby Square during different historic times showing different plans of the square. (a) French Gardens in the 1930s, (b) Tram and bus station in the 1950s, and (c) Current state of Oraby Square in 2008, all adapted by F. Hussein (2020)

6.4 Current state

The urban character of ElMansheya Square is continuing to degenerate due to various factors. The main reasons of such degradation were the lack of maintenance and lack of strict regulations and application of such regulations on the state's behalf. The degraded of the urban environment is very clear by observation, given the current state of the buildings, the crumbling sidewalks, and flooring of the passages. Demographic pressure has led to overcrowding in public spaces. Traffic chaos and the presence of street vendors occupying every available inch of pavements in a poor state are a consequence of mismanagement and the decline of the state's role in the conservation of the built environment and the organisation of urban space.

The current state of ElMansheya Square decreases the possibilities that the square could hold as an open public urban space. The unique design of the gardens, the statue of Mohamed Ali and the Unknown Soldier as landmarks, the skeleton of the heritage building façades, and the timeless importance of the area, all provide social, economic and environmental values that could generally enhance the quality of life of the inhabitants of the area, as well as providing stable, secure and profitable revenue capable of sustaining their future and the future of the square.

7 PUBLIC PARTICIPATION

Kevin Lynch (1960) developed the concept of imageability, which is the ability of urban elements to evoke a strong image for an observer. As cities grow, planners and designers strive to improve liveability in the built environment, thus improving the quality of life. There must be an accurate framework that contributes to quality streetscape. One of the effective methods to ensure quality streetscape is taking public opinion into consideration. Public participation can present variables that help develop an urban space or a liveable street better to carry out the intended activities and create memory as well.

Traditional surveys and hand-out questionnaires may have some spatial scale limitations leading to lack of precision and measurement inaccuracies. However, given the developed web-based strategies to record crowd-sourced perceptions, more precise and spatially extended measurements are available. Therefore, surveys have become an indispensable tool for collecting data. The survey questions aim to identify the importance of the case study in terms of memory and identity, as well as the important streetscape elements with the highest influence.

7.1 Survey

The surveys conducted in this case study were both on-site and online. The on-site survey was aimed at the static users; those who have constant contact with the place, such as shop owners, vendors, and residents. The online survey was aimed at the mobile users; those who are considered visitors and shoppers. Interviewees were told a brief introduction about the qualities of place and the main four categories of streetscape elements. It was also explained to them the main effects of streetscape elements on the qualities of place, and vice versa. The architectural and urban design principles were briefly shown to interviewees through different examples in the city of Alexandria, as to further show the streetscape elements surrounding any user. The qualitative data resulted from the survey will show the important design attributes in streetscape design that enhance identity and character.

The survey sample was calculated according population. According to demographic statistics from the Central Agency for Public Mobilisation and Statistics (CAPMAS) (City Population, 2021), the population of ElMansheya is estimated to be 24,087 covering an area of 0.6523 km2. In order to conduct the survey, a sample of about 300 interviewees was targeted, allowing a margin of error of 5%. Therefore, the required number of interviewees is estimated to be around 1200 interviewees to achieve an estimated response rate of 30%.

The survey questions aimed to explore the memories, emotions, and experiences between the interviewees and the case study. The survey was divided into three parts. The first part consisted of general questions about gender, age, reasons of visiting ElMansheya Square, duration of time spent on site, and the frequency of visits. The second part addressed the local identity of ElMansheya in terms of the existing memories of visitors and inhabitants and the ranking of the qualities of place. The third part consisted of likert questions that investigated the level of agreement of the interviewee with the streetscape elements of the site and the ranking of the important physical features that could enhance the identity and character of the site.

7.2 Survey Results

As a result of the nature of ElMansheya Square, being a commercial centre for downtown Alexandria, and the wide variety of products available, shopping was expected to be the main reason for visiting ElMansheya Square. Also, given the fact that a garden exists, it was expected that a fair number would visit ElMansheya Square for leisure purposes as well, such as jogging, walking and just enjoying the gardens. However, this purpose was presented in only 22% of the interviewees. About 20% visited ElMansheya Square on a regular basis a few times a month. Only 13% visited the gardens daily, and it is expected that the majority of this percentage were workers in the site. A vast 52% of participants visited ElMansheya Square and spent hours there. Given the fact that the most important reason of visiting was for shopping, then it is expected that the hours were spent in the shops and the commercial centres rather than in the gardens themselves.

A vast majority of 57% agreed that the Square was not linked to any personal memories and that was mainly because of the result of the current state of the Square. Many participants agreed that if the Square was in a better state, then maybe it would have been linked with memories and the possibility of future memories as well. This shows the strong relation between the physical aspects of the place and the memories it shares with participants.

Concerning safety and comfort, approximately 57% agreed that they do not feel safe and comfortable in ElMansheya Square as opposed to the 43% who did. The main reason that explained this reading was the lack of security members and the constant presence of homeless people and street vendors. Also, a major factor that contributed to this percentage was the lack of proper maintenance of lighting fixtures for a well-lit safe garden space.

About 62% agreed that ElMansheya Square had a unique identity. This high percentage proves that the Square already has potential to stand out and just needed some tweaking. The potential and scope of improvement expanded when the participants acknowledged the unique identity and special character that ElMansheya Square had.

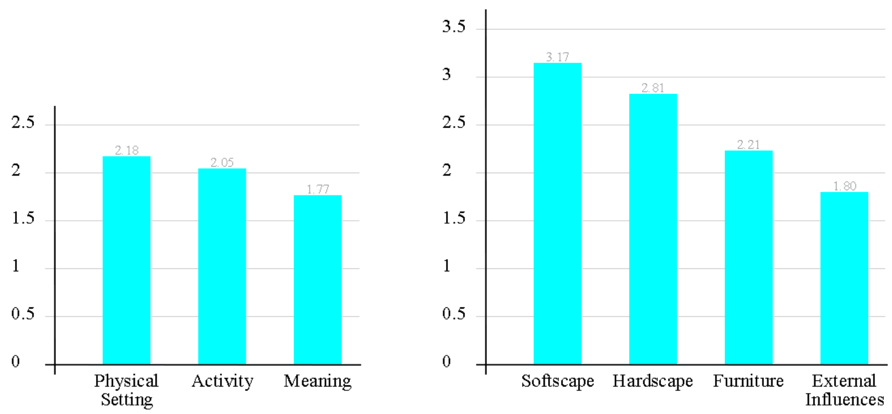

Fig. 5: Scores for the ranking of "Qualities of Place" left and "Elements of Streetscape" right, (by author)

When given the chance to arrange the qualities of place, participants agreed that the main quality was Physical Setting ranking first with a score of 2.18, followed by Activity and Meaning with respectively, as shown in Fig.5 to the left. This reading shows the strong impact of the Physical Setting on a space. It also shows that the possibilities behind a well-prepared and maintained setting are vast and encourage a large scope of improvements.

Also the most important element in streetscape composition was the Softscape elements ranking first with a score of 3.17, followed by Hardscape, Furniture elements, and External Influences respectively, as shown in Fig.5 to the right. Many participants agreed that the softscape features, most significantly tree canopies and grass cover, made a strong impact on the sense of comfort of the space. Another important aspect was that the greenery increased the feeling of "fresh air" and canopies and hedges somehow acted as a buffer from the vehicular lanes surrounding the gardens. Various older participants asked that facilities for elderly and handicapped users should be added, such as ramps, benches, and properly paved walkways.

Another important reading was the 71% that agreed that ElMansheya Square was properly used as an open space. This compliments the 57% that agree that the gardens encourage a wide range of activities, but only if well-prepared and constantly maintained. Along the survey, several participants noted the same things to be changed in ElMansheya Square in order for them to feel more of a sense of belonging to the space. Various participants asked for more security presence, pedestrian streets surrounding the gardens from specific sides, designated shops for current street vendors, and the total absence of homeless people and beggars. Other aspects consisted of suggestions such as no fencing for the gardens' perimeter; however hedges were a preference, better pavements and ramps, constant maintenance of furniture elements, cleanliness of gardens, and increasing lighting fixtures.

In this context, related institutions must analyse public open spaces in the city from a participatory perspective to develop the three qualities of place. The improvement strategies suggested should be based on a combined approach of urban design principles and heritage conservation laws. This will provide for a more balanced way to provide a strong future basis for user-and-urban-oriented design decisions, with respect to the historic importance of the site and its envelope.

8 CONCLUSION

The findings in this paper indicate that application of streetscape elements composition requires a deep understanding of various factors, such as the urban context, existing environment, socio-economic, community, and cultural conditions, and the historic background. The community character and identity is strongly related to the values and traditions of a community and needs to be celebrated through elements and layers of streetscape, along with the overall imageability. Streetscape composition should focus on the main intervention tools that enhance identity and character. The introduction of theoretical guidelines to develop and revitalise historic spaces is crucial. Intervention tools can vary from removing unsympathetic elements and activities to completely redesigning a space with the surrounding envelope. The extent of each interventional decision taken is based on its importance and effectiveness.

However, all intervention methods were highly recommended in ElMansheya Square to better enhance the gardens in terms of identity and character. This will eventually result in a proper urban space that acts as the lung for the neighbourhood and probably surrounding ones, as well as an attraction point for tourists and outsiders given the historic importance of such an amazing site.

1 ABSTRACT

Globally, countries are challenged with traffic congestion and many solutions have been done to encounter this challenge. Many developed countries have managed to deal with the challenges of the traffic congestion through the implemented strategies by each country with challenge. This paper is set to study the drivers of the traffic congestion which results to numerous negative impacts and address the environmental and socio-economic challenges created by high usage of private vehicles in the City of Johannesburg, South Africa. Further, the authors consider solutions to reduce traffic congestions through the assistance of the 4IR technologies. The methods selected on this study follow both quantitative and quantitative approach using different graphs for traffic analysis illustrating the traffic data, and the use of ArcGIS software will be deployed to create a map indicating roads with high volumes of traffic. The preliminary results indicated that many private vehicles on the roads have a greater contribution in traffic congestion especially when accidents happen, rotational load shedding in the city, different peak hours of the day which this has a negative impact on the economy as it reduces the productivity of the city. The implications of the study indicate that the usage of private vehicles is more reliable than the use of public transport which results to high traffic congestion volume during different intervals and there are less technological efforts deployed to reduce the ever-rising challenge of traffic. However, the study recommends the adaptive traffic signals, real-time traffic monitoring, smart corridors, and pedestrian tracking systems with advanced V2I technologies. With this, there are possibilities of reducing the traffic congestion in the City of Johannesburg.

Keywords: Traffic congestion, 4IR, City of Johannesburg, private vehicles

2 INTRODUCTION

Globally, countries are challenged with traffic congestion and many solutions have been done to encounter this challenge. Many developed countries have managed to deal with the challenges of the traffic congestion through the implemented strategies by each country with challenge. The Republic of South Africa is a developing country with urbarnazation taking places daily, people moving from rural areas and other countries to cities for better opportunities. The City of Johannesburg Metropolitan Municipality which is located in the Gauteng province (state) contributes a lot to the economy of the country and afford a lot of opportunities to both its citizens and people from other countries. This leads to population growth, the infrastructure to service the city becomes overwelmed and different challenges arise which needs soution at some point. The movement on the roads becomes too much at points leading to traffic congestion and this is a global challenge when a city is too populated. Operations of the city becomes very slow as people spent time in traffic jam resulting to the affect in the economy and other importance services. Therefore, need for viable solutions that are used by the developed cities such as making the City of Johannesburg to be intelligent. An intelligent city uses the information to make their cities more livable, sustainable, and enjoyable compared to traditional towns. While smart cities are the future of urban landscapes, every piece of technology in a network needs to work together flawlessly so that community leaders can implement strategies to accomplish their goals (Giarratana, 2019).With the adoption of the fourth industrial technologies in the city, this could control the traffic jamming and make the city to more effecient, and resulting to a productive economy.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

3 LITERATURE REVIEW

3.1 Modes of transportation on the roads

Transportation is the physical movement of passengers and goods from geographical location to another to enhance their utility (Akintayo, 2010). There are different kinds of transportation on roads which entail public and private transportation. These modes includes bus, minibus taxis, motor vehicles and motorbikes. All these modes of transportation use the roads at once and there are no designated times to use the roads. These leads to roads being flooded during the certain peak hours, in the morning, midday and early in the evening. Further, road transportation has average operational flexibility as vehicles can serve several purposes but can rarely operate outside roads. Road transport systems have high maintenance costs, both for the vehicles and infrastructures, which are related to low life spans. They are mainly linked to light industries and freight distribution, where rapid movements of freight in small batches are the norm (Rodrigue, 2020) .

3.2 Road Traffic congestion

Traffic congestion is a worldwild challenge created by many factors including urbanization, avoiding use of urban public transport, many private motor vehicles on the road, not many option of origin to destination roads, multi-functional traffic robots, non-proper manual systems and more technological systems deployed. As different road users form different locations moves towards the city at certain periods or intervals road become congested and the movement becomes very slow. Consequently, Giarratana (2019), states that congested roadways wreck havoc on the economy and culture of urban areas. Traffic causes significant problems for every aspect of a city, from the motorists that travel on public roads the roadways to the organizations that operate within cities to the residents that call them home. Some of the major complications that are directly linked to traffic include accidents, air pollution, noise pollution, reduced emergency assistance and reduced productivity. Accordingly, traffic congestion is a significant problem in many cities around the world. Jakarta, one of the most populous cities, faces this problem. However, there is different approach implemented to reduce the traffic jamming in the city such as strict policies and legislative frameworks on travelling patterns for road users, congestion charging and parking pricing reduce traffic congestion most if they are implemented for car based travel (Ilahi et al., 2020)

3.3 Fourth Industrial Revolution technologies (4IR) deployed for traffic control

The use of technology has ease down the pressure that canno be dealt with manually by people. According to McGinnis (2020), states that the Fourth Industrial Revolution is a way of describing the blurring of boundaries between the physical, digital, and biological worlds. It’s a fusion of advances in artificial intelligence (AI), robotics, the Internet of Things (IoT), 3D printing, genetic engineering, quantum computing, and other technologies. It’s the collective force behind many products and services that are fast becoming indispensable to modern life. Think GPS systems that suggest the fastest route to a destination, voice-activated virtual assistants such as Apple’s Siri, personalized Netflix recommendations, and Facebook’s ability to recognize your face and tag you in a friend’s photo.

4IR technology has a positive in traffic control. Artificial Intelligence (AI), for example, can improve urban planning by optimising routes for transport operators, reducing commuters' journey times particularly significant move given our urban layout. Municipal governments could utilise traffic data for the planning of roads and the monitoring of traffic patterns. This has already been successfully piloted in cities in the United States as the use of an AI system which detects vehicles in images from traffic cameras, the information is sent to a control centre, where algorithms analyse traffic density. The system detects congestion and direct traffic lights to re-route traffic, based on real-time data (Marwala, 2020).

The 4IR introduces technologies such as smart roads. Smart roads are roads that think, feel, predict the needs of the people and the vehicles that travels on them. Roads that have an environmental conscience help cause positive changes on the vehicles and improve overall safety with the aim of making difference to the world (Emilee, 2016). Consequntly, Adetayo (2017) mentions that smart-roads are also a form of stylized road infrastructures that communicate with vehicles, users, and components of traffic management to enhance safe, reliable, comfort, efficient, affordable, and digitilized means of transportation. The typical smart-road will be more animated than the conventional, it will come with sensors, data capture capabilities, ability to respond to changes in the environment and will be able to communicate with the vehicles.

4 STUDY AREA

The city of Johannesburg is located in the Gauteng province, and it is been regarded as one of the biggest metropolitan areas in South Africa, (The local government handbook, 2014). City of Johannesburg (COJ) covers an extent area of 1.645 square kilometers, (Smith, 2013). In the past decades the administration of the City of Johannesburg Metropolitan Municipality was decentralized initially into 11 regions these new regions were subsequently reduced in number to 7 regions (A-G) in 2006 (Smith, 2013).

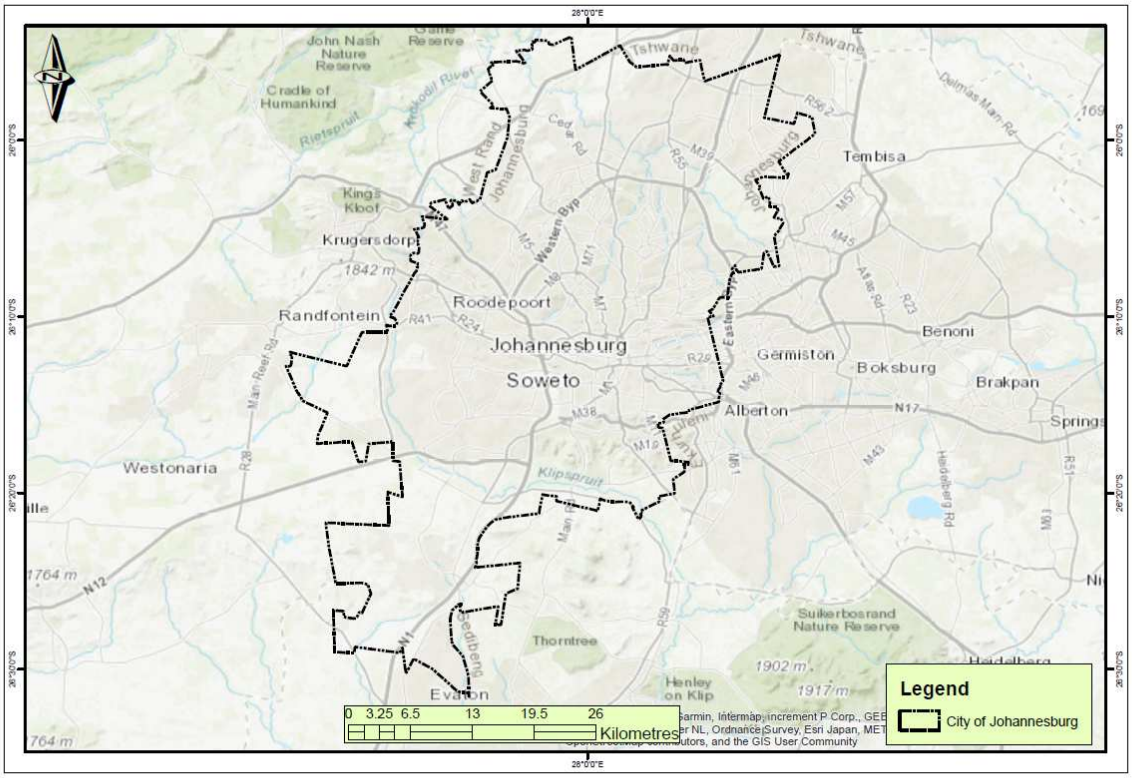

Figure 1: COJ Map [Source: Authors, 2021]

According to (SAIRR, 2014) South Africa's large population lives in urban areas, as an aftermath of urbanization over past years. High economic development in such urban areas has also attracted people to cities looking for better opportunities.

5 METHODOLOGY

A mixed method research design was adopted were quantitative data and spatial data analysis was used. Various research instruments were employed in the study such as Tomtom traffic index which provide accurate traffic information in real-time and statistics of previous information . This assisted to give the inside of the study to identify the traffic flow that happens, daily, monthly and yearly. Accordingly, a survey was conducted were road users were provided with questionnaire to understand the road patterns and what causes traffic congestin mostly. 30 road users who were provided with questionnaire are daily road users as they might have different experiences taking place daily. Purposive sampling was adopted as it is necessary to extract the necessary information of areas and times that are mostly affected by the traffic congestion. ArcGIS assisted with creating the City of Johannesburg map showing most roads that are affected by traffic jamming towards and out of the city. Map creation indicating the most areas affected by traffic, statistics from Tomtom and documented studies were the main sources of data. Comparative analysis was conducted in order to see the changes on traffic when the city was affected by the COVID 19 pandemic especially in 2020 and in 2021 when restrictions were eased down and there was lot of movement on the roads daily, and to identify the fourth industrial technologies deployed in the developed cities managing to control the traffic congestion. Further, content analysis was employed to review previous documented studies. Secondary information used was obtained from larger data base such as Scopus, Science direct, Sage and Google scholar.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

6 RESULTS AND ANALYSIS

6.1 Roads affected by traffic congestion in the COJ

The City of Johannesburg (COJ) is one of the busiest areas in the republic which makes the movement on the road busy and mostly leading to high level of traffic congestion. There are several factors that leads to traffic congestion in the COJ such accidents, multi-funtional traffic robots especially when there is load-shedding (no electricity power), traffic officers normal routine of ensuring non-corruption activitties are taking place, the huge population number of people travelling towards the city creates traffic congestion. Which becomes a very huge concerns for all users travelling times to places of interest and affecting the productivity of individuals impacting the economy negativily.

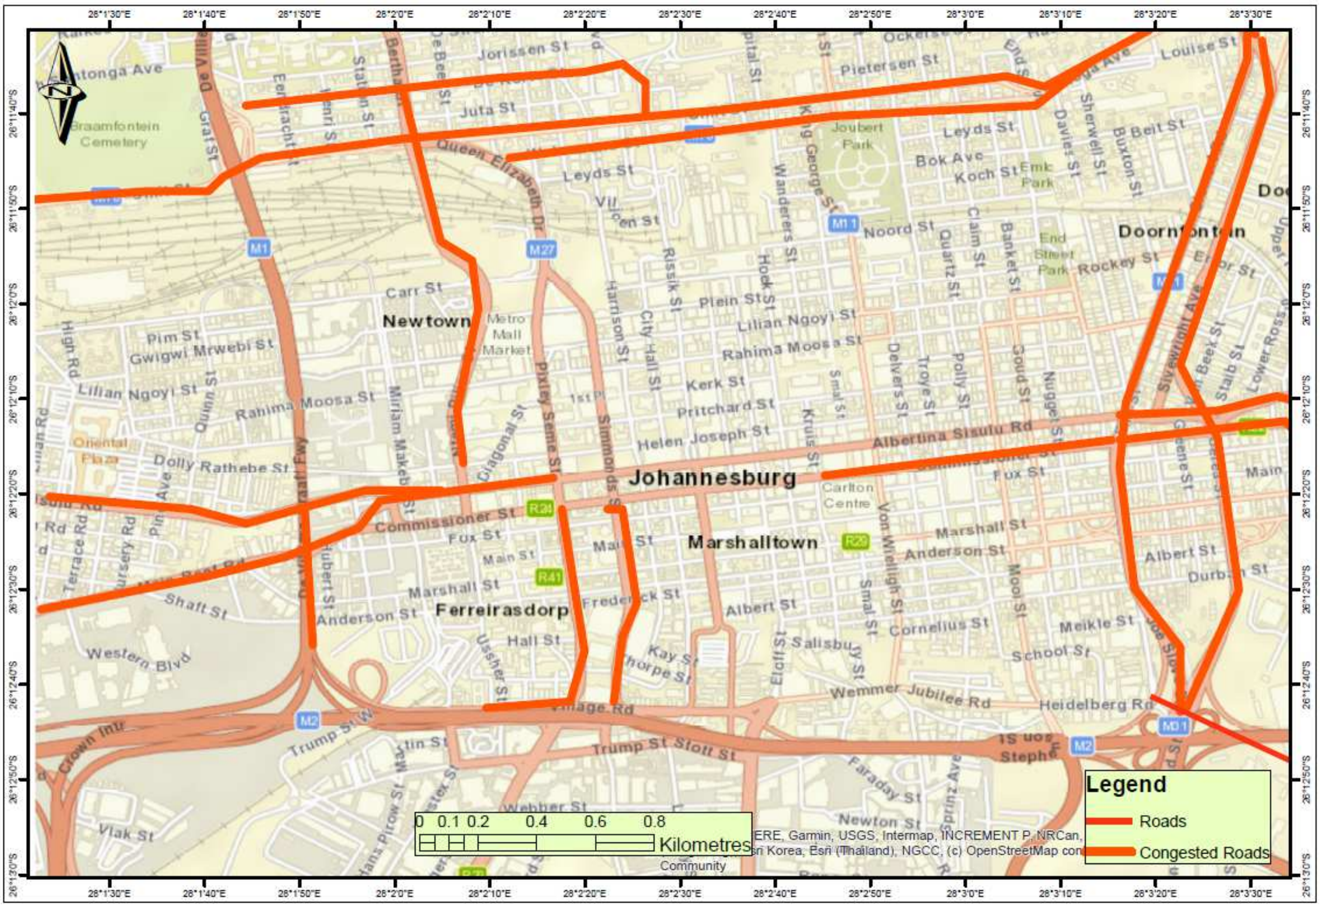

Figure 2: COJ traffic congestion Map [Source: TomTom, 2021]

The above figure 3 indicates the City of Johannesburg road network and the roads that are mostly congested. Roads that that highly congested are represented by the orange colour and mostly used major roads in the city are represented by the red colour. The main reef road and Albertina Sisulu road from the west of the map, mostly during peak hours have a high traffic congestion normally when road users are going to work in the morning and during midday towards the city. Consequently, the same amount of traffic congestion is noticed during later in the day and early evening when road users travel back home from different places of interest. De Korte street and Smith street from the north of map is mostly congested during the midaday as this roads service the Braamfontein area which serves as a CBD providing major economical services and also in the early evening when road users travel back home. Sivewright Avenue and M31, noticable is affected by high level of traffic congestion in the early evening from the Doornfontein area as most road users use the road to connect to the M2 and M31 which are the major roads serving travellers different urban areas of the city of johannesburg metropolitan area.

6.2 Congestion levels in the City of Johannesburg

The level of traffic congestion differ by months which this is sometime caused by different activities that take place daily.

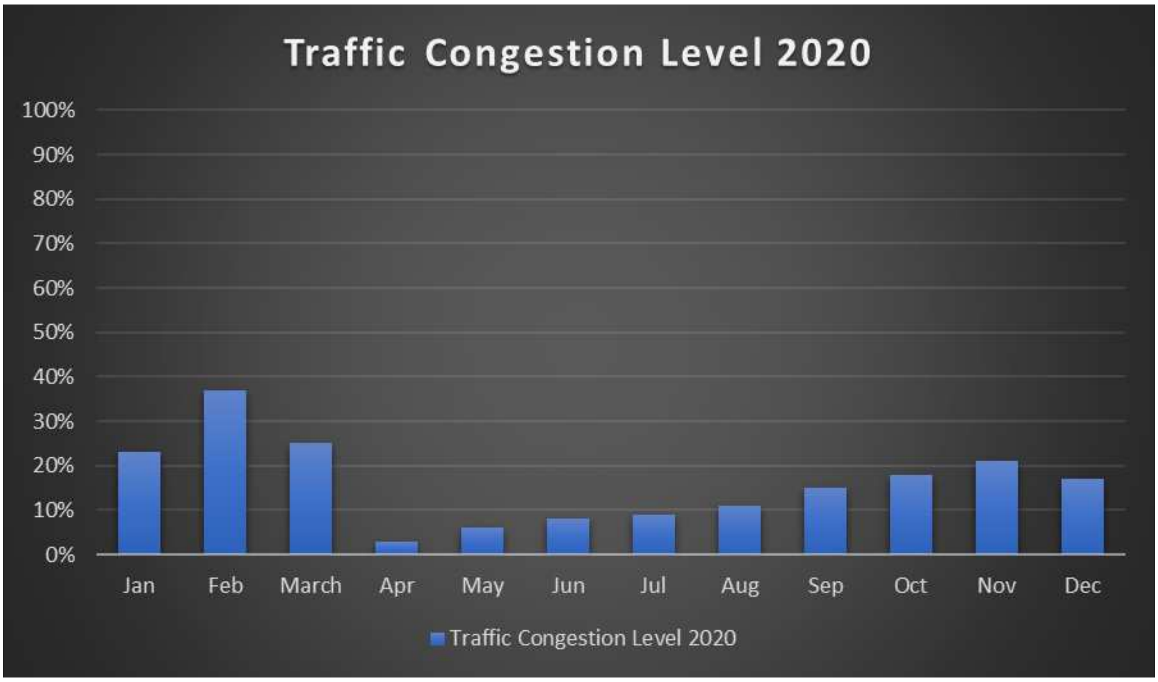

Figure 3: Traffic congestion level 2020 [Source: TomTom, 2021]

In the year 2020 traffic congestion in the early months of the year was high due to the normal state of the cities functionality and in the middle of the year traffic congestion dropped. This was due to the global pandemic that hit the country and the restrictons were put in place as the coutry was shutdown to a lockdown strictly movement was implemented and monitoring. Travelling was not permitted and only allowed due to certain conditions. During the first month of the year, January had average of around 25% percent as some of the workers and users of the road had to start travelling making daily trips. In February, the rest of the firm and institutions re-open, workers and users of the road also had to start travelling making daily trips which made the rate of traffic congestion to go up by 13%. In March, there was a reduction in traffic congestion as the pandemic was in the country, with announcement of awareness for travelling, travelling to certating areas of interest by the road users decreased by 11%. Consequently, in April, the traffic congestion dropped immesely to 3% as in late much the country was shutdown to lock down and only a certain percentage of movement was existing. Further, in the middle to later on year the restrictions were being eased to open some areas of economy from around late May to Novemember which is why the graph is scaling up from May to Novemebr. Further, in December, as it was the festive season, restrictions were lifted to combat the pandemic and the movement was restricted a bit and other operations in the city went on break due to festive, therefore, the traffic congestion reduced by 3%.

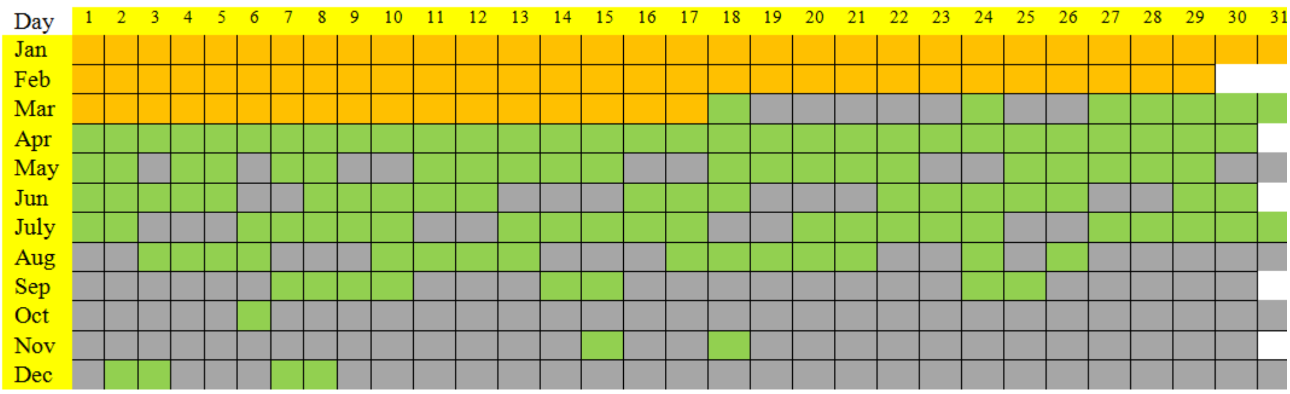

Figure 4: COJ Days with traffic flow [Source: TomTom, 2021]

The above figure 4 indicates the days with and without traffic congestion in the City of Johannesburg from January to December 2020. The Orange colour indicates the day with high level congestion at peak hours of the day. The green colour indicates days wereby there was less traffic congestion and the grey areas indicates the day with average traffic congestion and affected by the pandemic restrictions. As seen on the above table from January to the middle of March the daily traffic congestion was high and later on the month the traffic

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

eased down due to travelling restrictions introduced to the country. As it can be noted the pandemic had an major effect on travelling in the year 2020 as from April the high level of congestion were eased down.

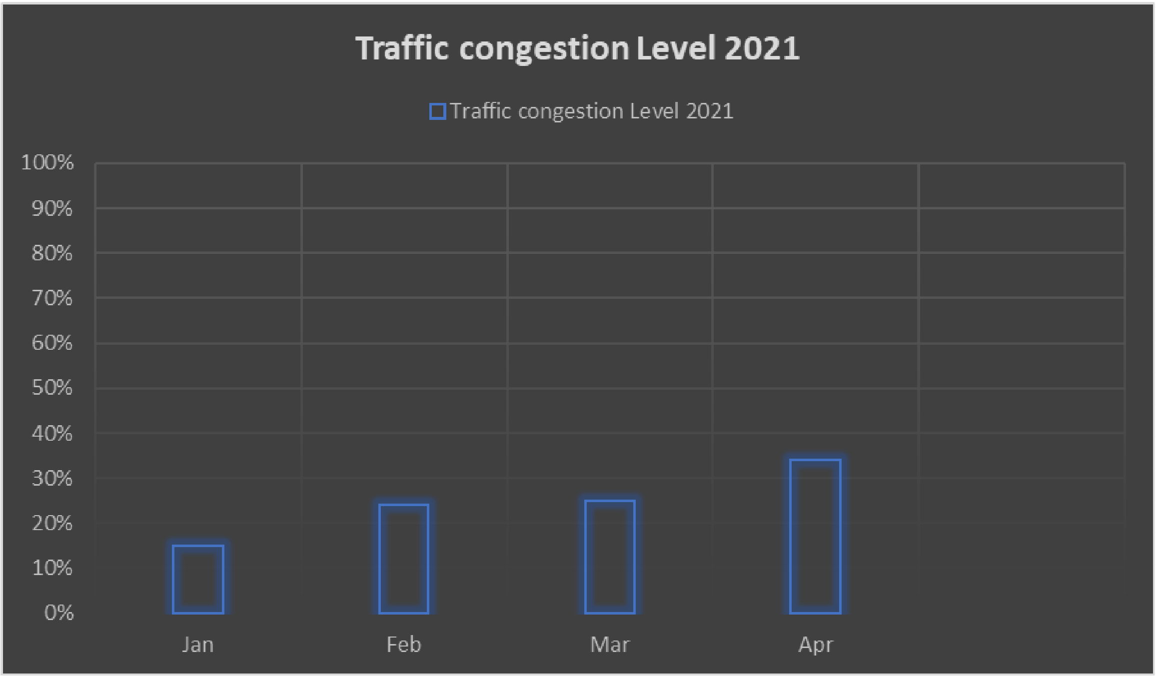

Figure 5: COJ Traffic congestion level 2021 [Source: TomTom, 2021]

In 2021, the restrictions were eased down due solutions were identify to combat the pandemic and most operations were operating but must converted to take places from home than office and lot of online working was happening. The traffic congestion in 2020 early in the year compared to 2021 was slightly more less the same in January and February but in 2021was a bit lesser. In March and April 2021 traffic congestion was very high as more economic activities were opened and more daily trips by users of the road were taken.

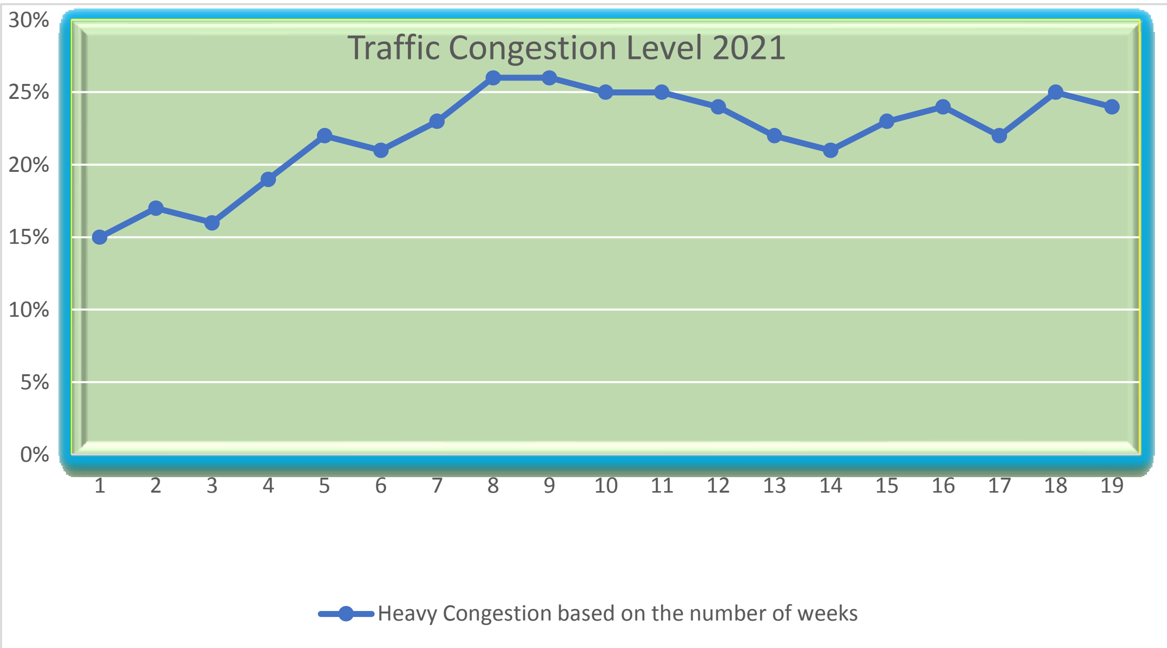

Figure 6: Weekly congestion level 2021 [Source: TomTom, 2021]

The above figure 5 indicates the level of traffic congestion in the City of Johannesburg from the first week of January to the second week of May. The above indicates that traffic congestion level in the first week of January to the fourth week the traffic congestion was between 15% to 20% as some of the operations in the city were still not open and due to working from home. In the first week of February to the last week of

February the level of congestion was going high and in the last week of February had the high level of traffic congestion due to the economy opening up. In the weeks of March and April the level of traffic congestion were declining due to some restriction in the country and holidays inbetween resulting in less travelling. However, the level of travel congestion was high at peak hours of the day.

Figure 7: COJ rush hour [Source: Authors, 2021]

The above figure 7 indicates the rush hour times in the City of Johannesburg wereby traffic congestion take place. As indicated in the above figure, it can be noticed that most days with high trafic congestions are Mondays to Fridays during 6:00 am in the morning to 8:00 am in the morning whereby most of the users are travelling to work and other city operations, and from 16:00pm to 18:00pm when most of the road users are travelling back home. With the introduction of the fourth industrial technologies, it will be workable to bring a solution when knowing when is the traffic congestion challenge is at its highest and how it can be combated.

7 CONCLUSION

Not only can traffic make the most patient people frantic, but traffic can also have a significant drag on the economy. A trip that should take no longer than 20 minutes can turn into several grueling hours, which caused by bumper-to-bumper traffic. Traffic congestion is the result of cities having more drivers than in the past with outdated maintenance, planning, and infrastructure that is not able to handle the needs of public roads (Giarratana 2019). While not often thought of in this way, traffic congestion is becoming a national crisis and needs to be addressed by city planners using advanced technology to help alleviate stress on public road infrastructure. City of Johannesburg must handle millions of drivers on the road at once. The city feels the stress of drivers battling traffic daily. Having a hundred of thousand of drivers stuck in traffic can waste a lot of potential hours and millions of Rands on the economy. Therefore, there is a need to deploy the 4IR technologies to control the traffic congestion and ease down the pressure on the roads daily for swift and smooth movement. Traffic will continue to plague cities as more drivers hit the roads each year, and city engineers will need to look to cutting-edge technology to help the public have a healthier and happier life. Therefore, urban planners, policy and legislative framework makers need to find the right balance that our public spaces need to build a better future for our growing urban centres. The, city has no some sort of alternatives of controlling traffic congestion, the traffic jamming continues till the traffic flows. The traffic signal robots has proved that they are not enough to control the traffic jamming in the city, however, the situation becomes worse when there is no electricity for the robots to operates. Which this calls for more technological innovations that could assist the traffic officers to keep traffic flowing the roads.

8 RECOMMENDATIONS

Traffic congestion is not a new phenomenon, howerever, there are strategies that are being impleted globally through the use of technology to this challenge. The study recommends the use of adaptive traffic signals which allows cities to gain better insight about traffic, including the flow and the length of time cars idle at lights and The information can then be used to modify the timing of traffic signals so that they coincide with traffic patterns during the day, real-time traffic monitoring as this technology illustrates where public buses, taxis, and other modes of transit are located, it shows where parking spaces are available and so on, and smart corridors which this make sections of roads feature technologies that alert drivers of the upcoming traffic conditions, including any accidents that lie ahead, how long it will take them to reach a particular destination, impending weather events, and other obstacles that could impact driving (Giarratana, 2019). Smart corridors keep motorists “in the know” so that they can plan ahead, which in turn can help to ease traffic.

1 ABSTRACT

This paper presents a decision support tool for public authorities and planning experts developed within the scope of the transnational project SaMBA, which focuses on reward and pricing policies to induce changes in the mobility behaviour of citizens. The tool presents incentive-based measures to promote low carbon mobility and raise awareness of the value of behaviour change policies as a foundation of strategic planning. Based on a user-defined goal and characteristics of the target area with influence on mobility or mobility behaviour, a list of recommended measures including details regarding implementation and impacts derived from best practices is provided. The tool is implemented with Microsoft Excel, which allows access for a wide audience, and ArcGIS, which provides additional analysis and visualisation options for users with GIS experience. The goal was to develop an extendable planning tool, which can be used as a foundation of the identification of potential measures and action areas.

Keywords: Sustainability, Incentives, Decision support, Behaviour change, Mobility

2 INTRODUCTION

An important topic and enormous challenge in the field of urban growth is the future of mobility. Urgent problems in this regard still are the high modal split and the energy demand of the private car, which are related to several issues including congestion, pollution or noise. Although motors have become more energy-efficient, the energy demand has increased due to the higher weight and the higher motor power of modern cars. Furthermore, the occupancy rate has decreased. In Austria, the number of cars has increased by 26% between the years 2000 and 2016. The number of kilometres travelled by car has increased by 28% at the same time (VCÖ 2018). In addition, citizens in some areas are still strongly car-dependent in their everyday mobility. The transport sector is the second largest producer of greenhouse gas emissions in Austria. In 2019, it was responsible for 30% of all emissions (Umweltbundesamt 2021). Many cities and regions already address these challenges by an improvement of public transport networks, an extension of walking and cycling infrastructures or testing innovative and smart mobility solutions to promote sustainable mobility and increase the quality of life. These measures certainly create a necessary and adequate basis, but for optimal use, they require additional awareness-raising approaches including incentive and reward systems to motivate people to use these new offers and change their mobility behaviour in favour of sustainable solutions. This is the context of the project SaMBA (Sustainable Mobility Behaviours in the [1]Alpine Region), which is implemented in the years 2018-2021 and promotes mobility behaviour change by reward and pricing policies. One output of this project is a tool presenting incentive-based measures to promote low carbon mobility and raise awareness of the value of behaviour change policies. The tool supports decision-making processes and the choice of appropriate measures and incentives addressing the mobility behaviour of residents. Based on a user-defined goal and the characteristics of the target area, the tool provides a set of suitable measures and their impacts. It contains two components implemented with Microsoft Excel and ArcGIS to combine the advantages of both approaches. The functionalities of the tool have been tested in the Salzburg Region, Austria and other SaMBA pilot regions.

3 STATE OF THE ART

3.1 Incentive theories

In the last years, governments have started to consider behavioural science to gain a better understanding of human actions as a foundation of the development of policies promoting sustainable behaviour (Mont et al. 2014). The SaMBA project aims at the support of this development by promoting mobility behaviour change as an important current topic. For implementing mobility behaviour change policies, it is necessary to

[1] https://www.alpine-space.eu/projects/samba/en/home

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

understand the basics of human behaviour. According to the Fogg Behaviour Model, behaviour consists of the factors motivation, ability and triggers, which have to come together at once for an action to be performed. To promote behaviour change, a person needs sufficient motivation, the ability to perform a certain action and a trigger for the target behaviour. Motivators can e.g. be hope, social acceptance or pleasure, but also pain or fear. Elements of ability are e.g. time, money or physical effort. Different types of triggers can e.g. help to motivate people to perform a behaviour or make a behaviour easier (Fogg 2009). In the case of the SaMBA approach, incentives are considered as motivating as they encourage people to perform certain actions. The SaMBA tool is based on the fact that people are pulled towards a behaviour that leads to a reward and pushed away from a behaviour that leads to negative consequences. This is also referred to as incentive theory, which is one of the major theories of motivation. It suggests that people are more motivated by outside incentives rather than by internal drives. According to incentive theory, incentives cannot only be used to promote certain actions, but they can also help to stop certain behaviours. However, incentives are only effective if the offered reward is obtainable and people consider it as important for themselves (Cherry 2020).

Due to the value and the effectiveness of incentives, incentive-based approaches regarding mobility behaviour change are already used in policy planning in some cases. They address different target groups, e.g. commuters, pupils, tourists or the general public, and topics like the promotion of public transport, active modes or sharing systems. These measures cover different spatial levels including urban, suburban and rural target areas. However, most of the examples collected during the SaMBA project focus on urban and suburban areas. Incentives come in a variety of forms, but a major group of them is based on rewards like money or vouchers for shops and restaurants. Others are e.g. raffles, activities like bicycle tours or practical rewards, e.g. cycling gear.

A major group of measures is based on technical approaches. Many of them use mobile applications that can also contain a gamification component. An example is TrafficO2[2], a mobile app that provides challenges and information to promote sustainable transport. The users can collect points for using sustainable modes to win prizes and discounts.

Gamification in general is also a common approach, especially when designing measures for children. An example is the Traffic Snake Game[3], where children can collect stickers for their class every time they walk, cycle, use public transport or a shared ride on their way to school. The goal is to collect as many stickers as possible to win prizes.

Another approach used in a variety of best practice examples is promoting a certain transport system with the help of discounts on the user fee. An example is CAMPUSbike[4], which is a programme that offers students in different German cities free bike rental for the first 30 min of the rental term.

Besides policies with an incentive or a reward, pricing approaches can also be used. They mostly include congestion charges like an example from London[5], where a daily charge for driving a vehicle within the charging zone needs to be paid. Some pricing approaches are included in the tool, however, the focus is on measures including a positive incentive.

3.2 Existing tools on sustainable transport

Another important foundation of the development of the SaMBA tool was the analysis of already existing tools to simulate the impacts of policies in the field of sustainable transport. These tools can be split up into different categories depending on their type. It can be distinguished between applications, Excel tools, models and other forms.

Most tools fall in the category of applications, which include web or software applications. As examples, “IMPACT”[6], which analyses changes in transport systems, the “Multi-Actor Multi-Criteria Analysis” tool[7],

[2] http://www.traffico2.com/en/

[4] https://www.nextbike.de/de/campusbike/
[5] https://tfl.gov.uk/modes/driving/congestion-charge
[6] https://www.ait.ac.at/en/solutions/impact-assessment-for-transformative-mobility-systems/
[7] http://www.mamca.be/en/

which measures the impact of policies on different stakeholders, or the “HIGH” tool[8] for analysing different impacts of transportation policies can be named.

Another way of analysing the impacts of policies is the development of Excel-based models. Examples are the “FLOW” tool[9], which concentrates on changes in the transport infrastructure and the “VMT reduction: Phase One – Scenario Assessment Tool”[10], which considers the impacts of CO_2 emissions and travelled miles.

Some other tools appear in form of a model, which can for example be mathematical, like the “Integrated Transport and Health Impact Modelling Tool”[11] or agent-based like the “Mobility Transition Model”[12].

4 STRUCTURE OF THE SAMBA TOOL

4.1 Framework

Although some tools regarding mobility and sustainable transport solutions already exist, only a few include a GIS component and are linked to the promotion of mobility behaviour change with the help of incentives. This is a gap that the SaMBA tool addresses by utilising Microsoft Excel, which provides a comprehensive but easy to use database with recommendable measures, and an additional ArcGIS component with more analysis options for users with experience in this field.

The primary target group of this tool includes policymakers, public authorities and planning experts, but also sectoral agencies, education and research and infrastructure or service providers. Therefore, the tool needs to be easy to use and to be open to a wide audience without any restrictions. It also is designed for transnational applicability. The main functions of the tool can be exploited by using the Microsoft Excel component on its own, which does not require expert knowledge and provides an environment most users are familiar with. Furthermore, it does not require constant maintenance after the end of the project and allows an easy extension. However, presenting results is limited to diagrams and tables. Since the tool has a spatial context, an optional GIS component has been developed to provide more detailed analysis and visualisation options. The main purposes of the GIS component are to improve the required user input by pre-processed spatial statistics or data and to identify and visualise mobility demands and potential action areas in a spatial context as an element of decision support. However, it addresses a smaller target group and is limited by the availability of standardised geodata on a transnational level. For maximum benefit and to circumvent the specific disadvantages, both approaches were implemented. The final tool does not require expert knowledge in the field of GIS, but it is helpful for more in-depth analysis and the visualisation of the results.

4.2 Building blocks

To be able to recommend suitable measures, the tool requires a dimension, a goal and a set of parameters for the characteriation of the target area. Based on these user inputs, a list of suitable measures is presented. Furthermore, the impacts of a measure are described based on best practice examples (cf. Fig. 1).

Based on the objective to introduce incentive-based measures that promote low carbon mobility and climate and environmental protection, four important dimensions for mobility behaviour change have been defined for the SaMBA tool. They include public transport, active modes, multimodality/access and sharing systems. Each goal embedded in the tool is assigned to the appropriate dimension for better clarity and structuring (cf. Fig. 2). Dimensions and goals have been defined with the help of pilot activities carried out during the project and regional, national or international strategic documents. One of the most important regional documents in this regard is the Mobility Concept of the Federal State Salzburg, which describes future strategies for sustainable mobility and transport policies. It defines goals including the promotion of eco-friendly and multimodal transport, the promotion of alternative and innovative approaches like sharing systems and the provision of equal mobility options for all residents (Land Salzburg 2016). Similar objectives are presented in the Austrian Traffic Master Plan, which introduces Austrian-wide transport political goals for all modes (BMVIT 2012). The European Commission has published a strategy on low

[8] http://www.high-tool.eu/index.php?id=home
[9] http://h2020-flow.eu/

[11] https://ithim.ghi.wisc.edu/
[12] https://www.top-ix.org/it/2018/06/04/disegnare-mobilita-sostenibile-con-motmo/

emission mobility, focusing on improving the efficiency of the transport system, promoting low emission alternative energy and zero-emission vehicles (European Commission 2016). The Transport Protocol of the Alpine Convention describes characteristics of a sustainable transport policy, which include e.g. reduction of negative effects on the environment, improved accessibility, optimisation of the use of existing infrastructures and measures against noise or emissions (EU 2007).

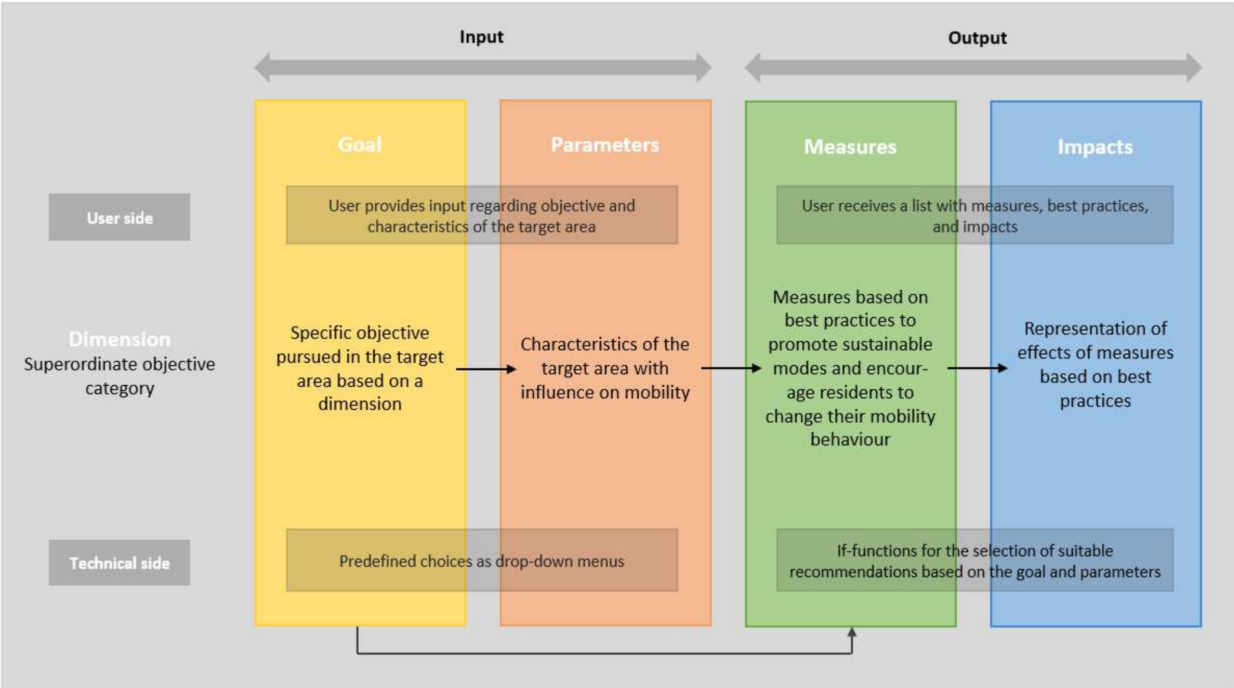

Fig. 1: Central building blocks of the SaMBA tool

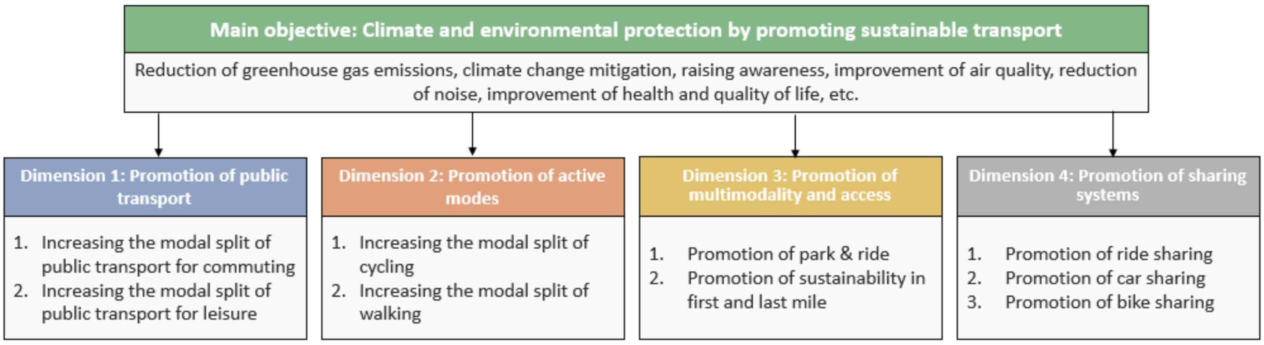

Fig. 2: Dimensions and goals

In the next step, the characteristics of the target area in terms of mobility and mobility behaviour are defined with the help of a parameter set. This set includes e.g. transport infrastructure and services, demography, topography and settlement (cf. Fig. 3). All parameters are embedded in Microsoft Excel, but some of them currently are not part of the GIS component due to data availability issues.

Based on the selected goal and the parameters, the SaMBA tool recommends measures that are suitable for the target area. In the context of the presented project, measures are defined as policies including an incentive to motivate citizens to change their mobility behaviour in favour of eco-friendly modes. Measures are presented along with their impacts, which are defined as effects based on an indicator. Mostly, they are quantitative and include e.g. changes in the modal split or the amount of CO_2 emissions saved. However, also qualitative impacts like health benefits from active modes are described since in some cases no specific studies on the impact and no quantitative data exist. Measures will not have the same effects in different target areas since they depend on many factors and details that are beyond the scope of the project. Therefore, the tool provides results and impacts derived from best practice examples.

Parameter name	Categories	Excel	GIS
Type of the target area	Urban, suburban, rural	✓	✓
Topography	Flat, hilly, steep	✓	✓
Quality of footpaths and sidewalks (density of footpaths, presence of sidewalks, street lighting etc.)	High, medium, low	✓	✓
Quality of cycling infrastructure (density of bicycle lanes, presence of adequate bicycle parking facilities, street lighting, pavement quality etc.)	High, medium, low	✓	✓
Quality of public transport (frequency, vehicle type, persons living in walking distance to a public transport stop etc.)	High, medium, low	✓	✓
Presence of high commuter flows (in and out)	Yes, no	✓	✓
Presence of a university or a university catchment area	Yes, no	✓	✓
Presence of a primary school	Yes, no	✓	✓
Presence of a secondary school	Yes, no	✓	✓
Presence of a bike sharing system	Yes, no	✓	✗
Presence of a car sharing system	Yes, no	✓	✗
Presence of a park & ride system	Yes, no	✓	✓

Fig. 3: Parameters

5 TOOL FUNCTIONALITIES

5.1 Workflow

Fig. 4 presents the workflow of the SaMBA tool. The starting point is the selection of a dimension and a goal with the help of dependent dropdown menus in Microsoft Excel. For higher user-friendliness, the tool only shows parameters that are relevant to a selection. Parameter inputs can also be selected as categories from dropdown menus. The user is not obligated to fill in all listed parameters, however, with a larger amount of input, the results will be more customised and adapted to the characteristics of a target area. After filling in the parameters, Microsoft Excel with the help of If-functions filters measures that are embedded in a database. As a result, the tool provides a list of recommended measures including a measure name, a best practice and indicators (e.g. modal split) the measure has impacts on. Further details regarding the implementation and the impacts are displayed when the user clicks on the name of a best practice example. Besides worksheet functions, the Microsoft Excel component also uses the programming language Visual Basic.

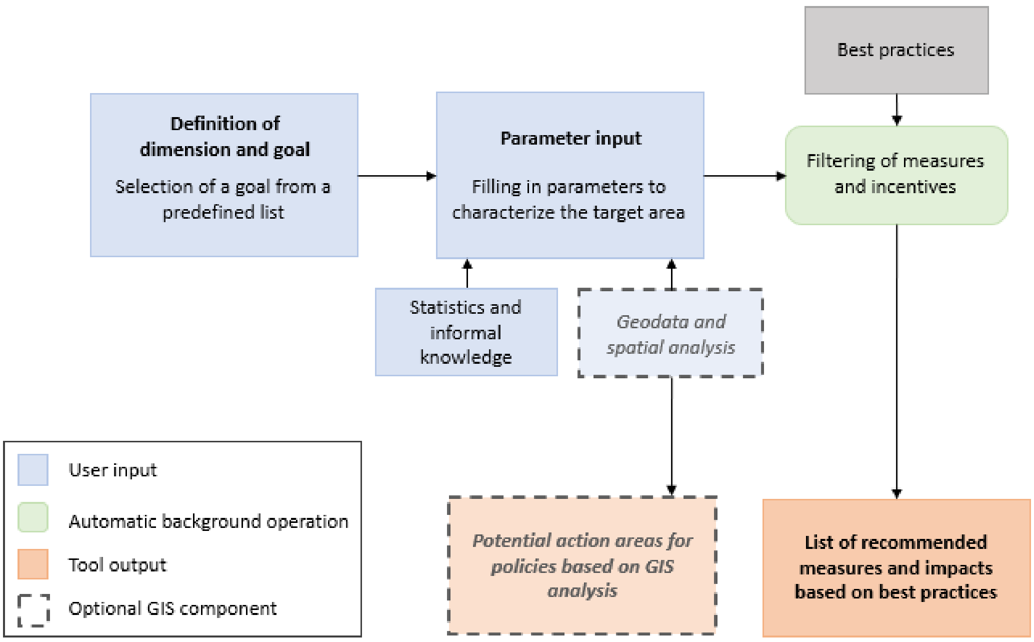

Fig. 4: Workflow of the SaMBA tool

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

The additional GIS component can be used in two ways. Besides sources like municipal statistics and informal knowledge, parameter inputs can also be derived from a GIS analysis of the region. The latter will help to get more exact values, consider areas beyond predefined borders or focus on small areas that are not listed in official statistics. With the help of spatial data regarding demography, topography, settlement structure, commuter flows and transport infrastructure or services, the required input parameters can be modelled in ArcGIS. The GIS component also offers methods for the assessment and comparison of mobility demands or potential action areas for behaviour change policies. Framing conditions based on the settlement structure (e.g. urban-rural-typologies and topography) and infrastructure quality for walking, cycling, public transport and intermodal trips are used for the identification of potentials. The idea is to detect action areas with an adequate infrastructure quality and a high potential for mobility behaviour change measures.

5.2 Interface and output examples

The Microsoft Excel component consists of six different worksheets. The first one is an introduction describing background information and the purpose of the tool. The second sheet represents the main user interface including all inputs and outputs. It also provides an export function, which transfers the sheet to a PDF document. For users who want to gain further insight into the collection of all integrated measures, an additional overview table is provided in the third sheet, which also allows filtering the measures by a goal. The fourth sheet contains a glossary defining important terms. The databases containing the inputs for the dropdown menus and the If-queries for the identification of recommendable measures are included in the fifth and sixth sheets, which are only open for tool developers. Fig. 5 shows the main user interface demonstrating inputs and outputs for promoting the use of public transport among commuters based on exemplary user inputs from a municipality in the Salzburg Region.

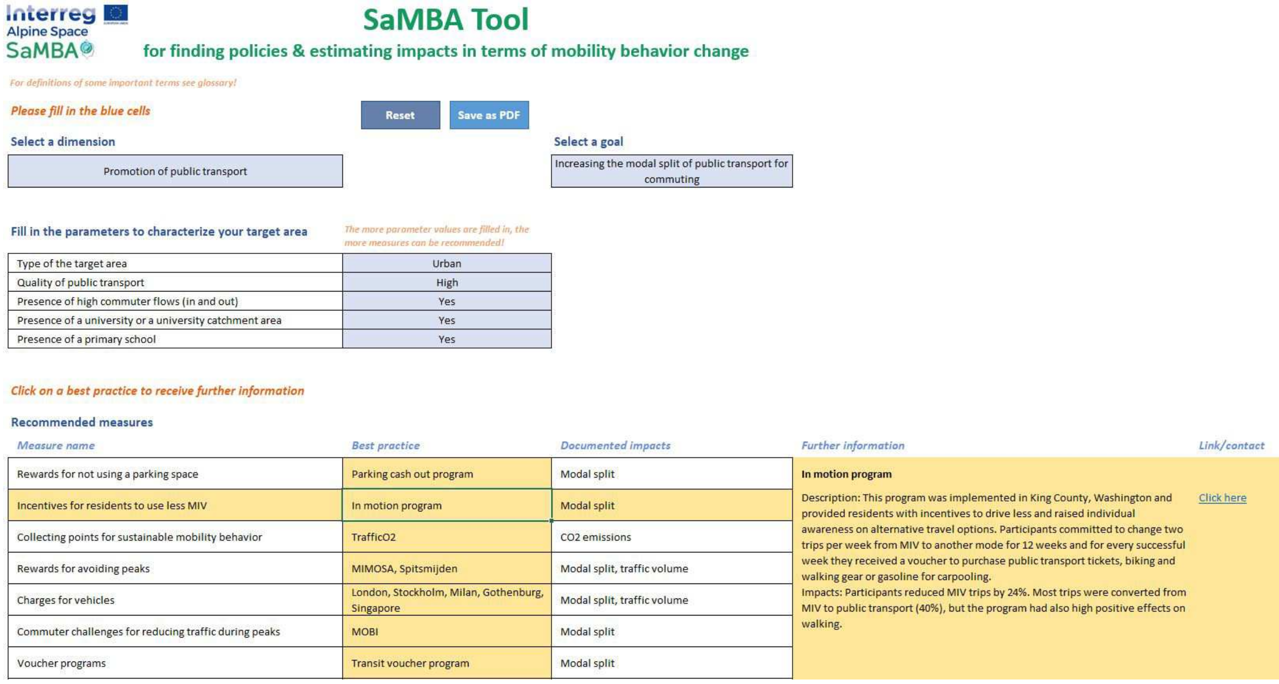

Fig. 5: Main user interface of the SaMBA tool

The impacts of measures are represented with the help of best practice examples. If no measure can be recommended for the target area, general suggestions (e.g. that it is required to improve the infrastructure before implementing behaviour change policies) are provided. Currently, the recommendation of measures and their impacts are only depicted in the Microsoft Excel component.

The ArcGIS component consists of 13 different models developed for parameter calculation and the estimation of potentials and demands. Fig. 6 shows the quality of public transport in a part of the Tennengau Region, which is located to the South of the city of Salzburg, based on a 250m raster. The results can also be transferred to other spatial levels like municipalities or settlement cores. The quality of the public transport system presented in the map is based on the “ÖV-Güteklassen” (classification scheme for public transport quality in Austria) and the walking distance to a public transport stop. The map shows that most municipality centres have very good public transport infrastructure, especially in the municipalities located in the

Northern part of the study area, which is nearer to the city of Salzburg. One reason for this is the existence of a train line.

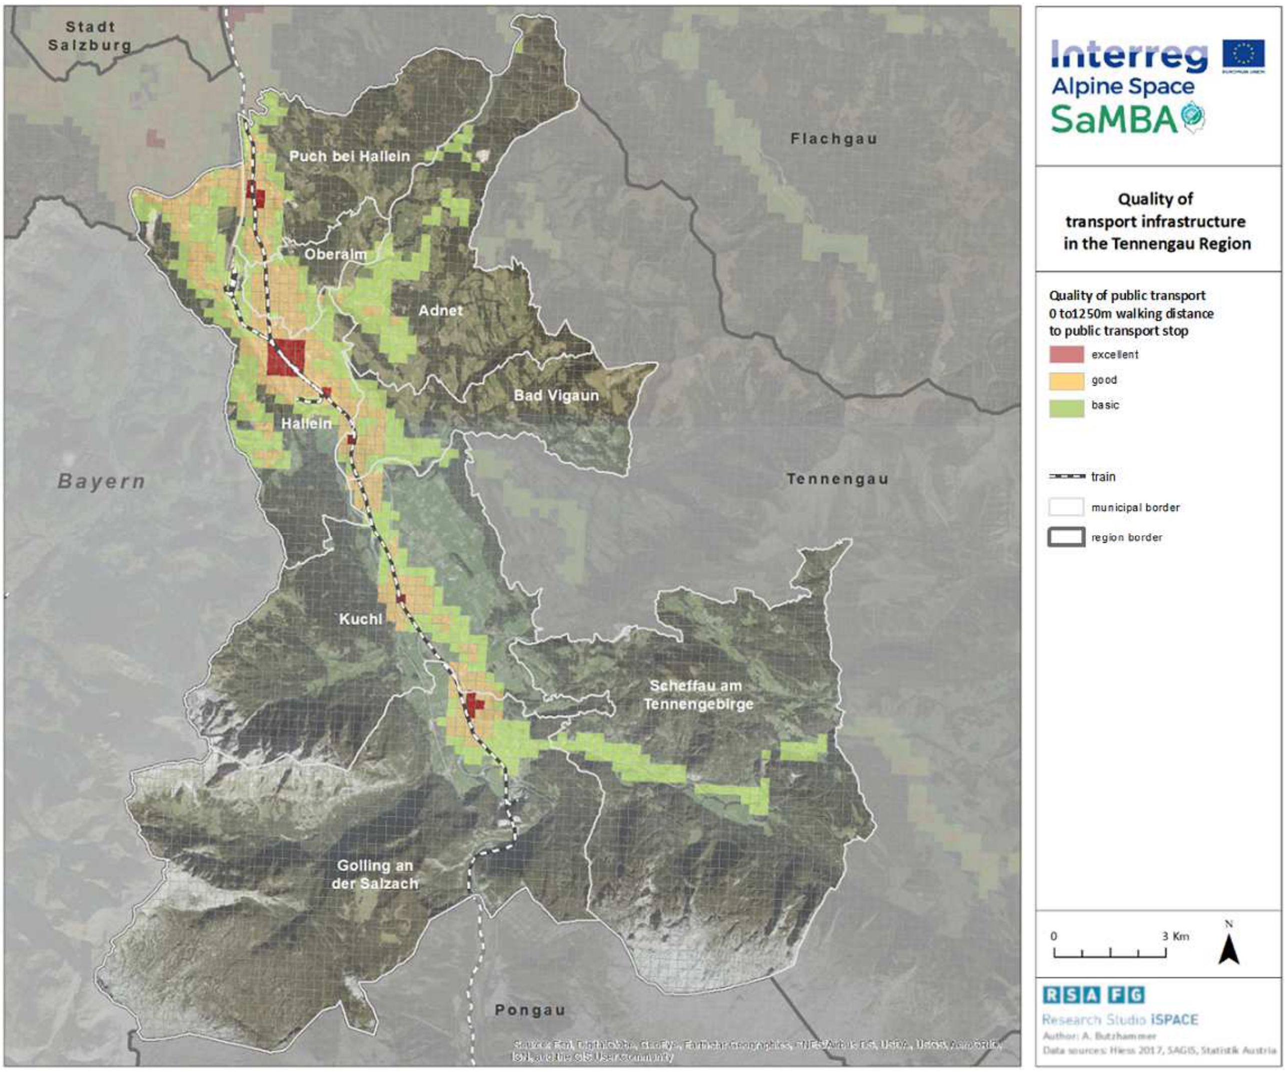

Fig. 6: Quality of public transport

Fig. 7 demonstrates the identification of potential action areas with the help of two maps covering the municipalities Hallein and Kuchl, which are located in the Tennengau Region. The first map represents the conditions for walking to public transport stops based on settlement structure, slope and the distance to the next public transport stop. Furthermore, the service interval and the vehicle type are considered, since for most persons the motivation to walk to a public transport stop with good service quality is higher. This output can e.g. be combined with potential modes for the first mile to public transport stops for commuters to determine action areas for measures that promote public transport and walking in the first mile. This is displayed in the second map, which shows the share of commuters with good first mile options for cycling, walking and the car. In this case, a potential action area for promoting public transport and walking in the first mile in the North of Hallein could be identified.

6 DISCUSSION AND OUTLOOK

The SaMBA tool provides decision support as a foundation for public authorities in strategic planning introducing recommendable measures that aim at a mobility behaviour change of citizens. The tool has the potential to be adapted in different ways. For an easy modification of the tool, the demonstration of possible extensions by additional goals, parameters or measures and further insight into the utilised spatial analysis methods, a guideline including detailed documentation of the tool workflow, the implementation process and all GIS models and Excel statements is provided.

The Microsoft Excel component provides an intuitive and uncomplex way to gain insight into different approaches. This component is considered a comprehensive database that easily presents existing solutions to allow an overview and a quick finding of measures for the user. Since its required inputs can be based on statistics and informal knowledge, it is of especially high importance in regions with limited geodata availability. Because the Microsoft Excel component does not require expert knowledge, it is open to a large user group, but it is limited regarding its outputs as it only allows diagrams and tables and no more comprehensive visualisation options.

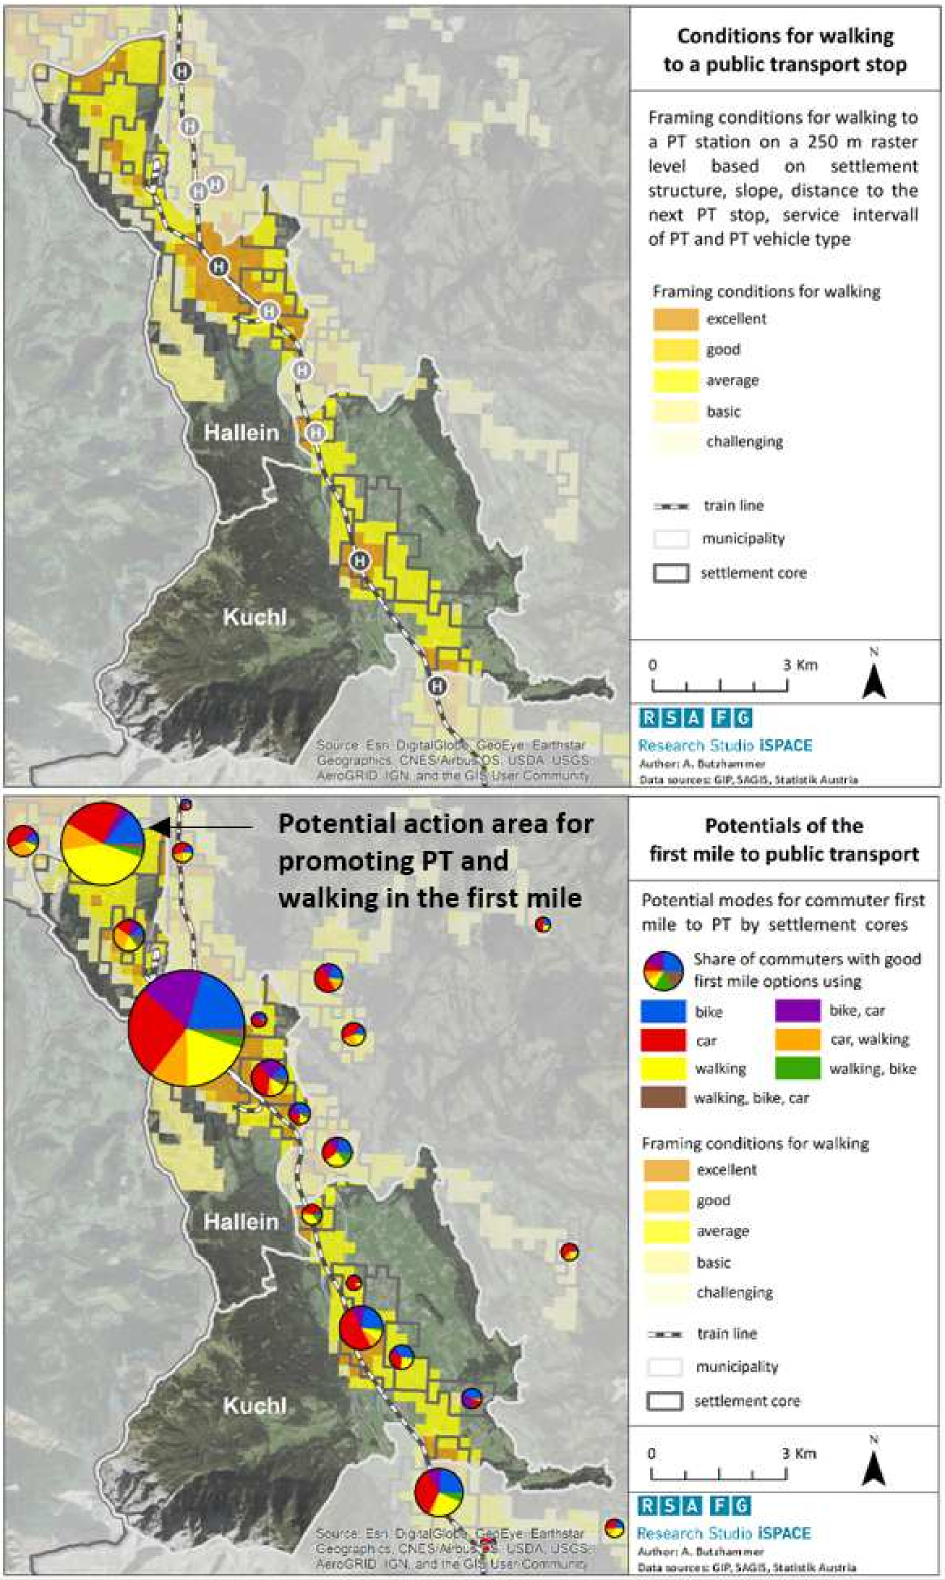

Fig. 7: Conditions for walking to the next public transport stop and potential action areas

The underlying concept of the tool is designed for transnational applicability, which means that the presented goals and parameters have no regional specification. The GIS component, however, is dependent on data availability in the target area, but it contributes to improvements in the results of the tool. GIS supports the development of regional analyses to identify suitable measures and to compare different target areas.

At the moment, one weakness of the tool is the strong dependence on best practices, especially in the field of impacts of measures. Currently, the tool does not allow a direct transfer of impacts or their calculation in the target area of the user. To address this issue, appropriate adaptations in the long term can help to estimate regional impacts of measures based on an interconnection with traffic information, commuter flows and effects on modal split and CO2 emissions. The tool has the potential to be further developed to allow the construction of scenarios and to simulate potential effects on congestion, occupancy of public transport, pollution and necessities to improve existing infrastructure.

Currently, although GIS and Microsoft Excel are considered components of one tool, they are not strongly interlinked. ArcGIS can present possible action areas, but it does not recommend suitable measures for these areas. An improvement in this regard would lead to more comprehensive analysis and interpretation options. Furthermore, a combination with other tools is thinkable for the future.

Gähnende Leere oder beliebter Park? Nutzung eines innerstädtischen Universitäts-Campus zur Zeit der Corona-Pandemie am Beispiel des Campus Süd des Karlsruher Instituts für Technologie (KIT)

Hanna Jäger

(Hanna Jäger, KIT, Institut für Geographie und Geoökologie, Kaiserstr. 12, 76131 Karlsruhe, hanna.jaeger@kit.edu)

1 ABSTRACT

Nur selten liegt ein großer Universitätscampus zentral in einem Stadtgebiet, wie das in Karlsruhe der Fall ist. Die angrenzenden Stadtteile sind von der direkten Nachbarschaft des Campus über die Jahre geprägt worden – eine hohe Zahl an Studierenden-WGs und die größte Dichte an Studierendenverbindungen in Karlsruhe sind dafür nur zwei Indizien. Innerhalb der Stadtviertel sind v.a. in den Sommermonaten häufiger Studierendengruppen anzutreffen, welche die Grün- und Parkflächen auf und außerhalb des Campus zum gemeinsamen Lernen und Verweilen nutzen. Doch seit Beginn der Corona-Pandemie und der damit verbundenen Maßnahmen zur Eindämmung der Verbreitung des Virus fehlt dieses öffentlich sichtbare studentische Leben in der Stadt Karlsruhe. Studien-, Lehr- und Forschungsbetrieb finden seit März 2020 überwiegend nicht mehr auf dem Campusgelände statt. In dieser Zeit konnte beobachtet werden, wie das Gelände als geschätzter innerstädtischer Naherholungsraum immer stärker genutzt wurde. Im Rahmen einer schriftlichen Anwohnendenbefragung in den umliegenden Stadtvierteln und einer mündlichen Passantenbefragung auf dem Campusgelände im März 2021 wurde die Bedeutung des innerstädtischen Campusgeländes für Anwohnende und Campus-Angehörige erforscht. Es kann bereits gezeigt werden, dass der Campus Süd des KIT für die Stadtbewohnenden und Campus-Angehörigen ein geschätzter innerstädtischer Naherholungsraum ist. Die Freiflächen des Campus fördern den Austausch und die soziale Interaktion. Durch seine sehr gute Anbindung mit jeglichen Verkehrsmitteln und der hohen Zufriedenheit mit der Erreichbarkeit des Geländes, kann die zukünftige Campus- und Stadtentwicklung aus diesem Potenzial weiter schöpfen. Die vermehrte Nutzung des Campus als Spazierfläche kann durch entsprechende Installationen im Hinblick auf die Bedürfnisse dieser Nutzendengruppe, wie beispielsweise Ruhebänke, öffentliche Cafés oder Bücherschränke, die Verweildauer auf dem Campus und so die Aufmerksamkeit auf wissenschaftliche Themen erhöhen. Dennoch sollten bei der zukünftigen Campus- und Stadtentwicklung immer auch die Vorteile eines in sich geschlossenen Campus bedacht werden. Die Idee der in sich geschlossenen Anlage fördern eine größere Ruhe, Kontemplation und Freiheit der Planung für die Campusentwicklung. Es ist daher zwingend notwendig, nicht nur eine Wunschvorstellung zu formulieren, sondern den Ist-Zustand der jeweiligen Campusnutzung am Standort zu evaluieren, um für die jeweilige Stadt die geeigneten Maßnahmen zu einer gewinnbringenden und angestrebten Verknüpfung von städtischem und wissenschaftlichem Alltag auf einem Campusgelände zu entwerfen.

Keywords: University Campus, Campus and City, Urban Design, Open Space

2 HINFÜHRUNG

Universitäten und Hochschulen treten in den letzten Jahrzehnten vermehrt in den Fokus der sie umgebenden Stadtentwicklung. Ihre Bedeutung wandelt sich dabei vom reinen Forschungs- und Lehrstandort sowie Wissensgenerator zu einem bedeutenden Bestandteil der Stadt, was bei einer näheren Betrachtung keine Besonderheit darstellen dürfte. Sie beeinflussen die städtische Infrastruktur, den Wohnungsmarkt und sind nicht selten wichtige Arbeitgeber mit einer Strahlkraft über die Stadtgrenzen hinaus. Zunehmend mehr Städte erfinden sich im Zuge dessen als ‚Wissenschaftsstädte' neu. Universitäten und Hochschulen erlangen identitätsstiftende Qualitäten für eine Stadt und stehen als Aushängeschild in (inter-)nationaler Konkurrenz, wenn es um die Anwerbung von Studierenden, Mitarbeitenden oder jungen Forschenden geht. Mit Konzepten zur besseren Integration von Wissens- und Stadtgesellschaft möchten Universitäten und Städte wertvolle Synergieeffekte generieren, um sich so gegenseitig positiv zu beeinflussen und voneinander zu profitieren (siehe dazu beispielsweise DEN HEIJER 2018). Je nach Anlage des Campus ist jedoch die (nachträgliche) Integration in das Stadtleben vor unterschiedliche Herausforderungen gestellt. Während Städte mit suburbanen Campussen eher Lösungen finden müssen, städtisches Leben auf den Campus zu integrieren, profitieren innerstädtische, ältere Universitäten, wie Heidelberg oder Freiburg, schon von der unmittelbaren Nähe von Wissens- und Stadtgesellschaft. Die Konzentration von Universitätsgebäuden auf einer zusammenhängenden Fläche und die Entstehung der heutigen Campusse kam im deutschsprachigen Raum erst allmählich zwischen den Jahren 1960 und 1980 auf. Die hier entstehenden Campusanlagen, wie beispielsweise das Neuenheimer Feld in Heidelberg oder der Campus Hönggerberg in Zürich, wurden bewusst auf die ‚grüne Wiese' verlegt, um sich dem Einfluss und der Ablenkung der Stadt zu entziehen. Ziel war es, einen reinen Wissens- und Forschungsstandort zu schaffen, der von äußeren Einflüssen so weit wie möglich ‚abgeschottet' ist (vgl. HÖGER 2007). Auch die Art der Gebäudestruktur und der Außenwirkung der Architektur lassen einen Campus häufig als einen „Fremdkörper im städtischen Gefüge" (ZIEGENBEIN 2009) erscheinen. Diesen Campussen wird heute eine Monofunktionalität nachgesagt, die keine angemessene soziale Umgebung schafft und negativ bewertet wird (siehe dazu beispielsweise NEGM et al. 2020). Angestrebt wird ein harmonischer Austausch zwischen Universität und Stadt, wie es im Laufe der Entwicklung der University of Cambridge beobachtet werden kann. Hier gibt es die Ansiedlung von Campusgebäuden an einem zentralen Standort schon deutlich länger. Harvard Square und Harvard Yard sind hier nicht nur Mittelpunkt für vergnügliche, erholsame Zwecke und städtischen Lebens, sondern eben auch Mittelpunkt des akademischen Alltags (HÖGER 2007). Einige städtische Campus-Anlagen, wie beispielsweise das bereits erwähnte Neuenheimer Feld in Heidelberg, kompensieren die Monofunktionalität des Campus durch die direkte Nähe zur urbanen Umgebung und deren Einrichtungen und Funktionen. Während das Neuenheimer Feld sich mit seiner geographischen Lage jedoch auch eher in einer ‚abgegrenzten' Lage befindet, finden wir in Karlsruhe einen traditionellen Universitäts-Campus in Innenstadtlage.

2.1 Campus und Stadt in Karlsruhe

Karlsruhe als Hochschul- und Wissensstandort beheimatet neun Hochschulen, eine bedeutende außeruniversitäre Forschung und ist mit dem KIT Sitz der größten deutschen Forschungseinrichtung. Das KIT entstand 2009 aus dem Zusammenschluss des Forschungszentrums Karlsruhe GmbH und der Universität Karlsruhe (TH). Beide Institutionen brachten zwei bestehende Campusanlagen mit in die Fusion. Die Universität Karlsruhe ist seit deren Gründung 1815 zentral in der Innenstadt angesiedelt. Das Forschungszentrum besitzt seit 1956 einen eigenen Forschungscampus angrenzend an den nördlichen Rand des Stadtgebiets, mitten im Naherholungsgebiet Hardtwald. Während der Sitz der ehemaligen Forschungseinrichtung, der Campus Nord, auch heute noch vor allem der Forschung vorbehalten ist und der Zugang wegen der Überreste der dort angesiedelten Kernforschung streng reguliert wird, findet die zentrale Lehrtätigkeit nach wie vor auf dem innenstadtnahen Campus Süd statt. Anders als beim Campus Nord wird hier lediglich die Zufahrt mit dem PKW reglementiert, für Fußgänger und Radfahrer ist der Campus Süd an vielen Stellen entlang der Campusgrenzen frei zugänglich. Die besondere Lage des Campus Süd wird mit einem Blick auf nachstehende Karte deutlich (ABB. 1). Der Campus Süd des KIT (hier schwarz schraffiert) liegt inmitten des Stadtgebiets Karlsruhe, u.a. in den beiden Stadtvierteln Innenstadt-Ost und Oststadt (türkis).

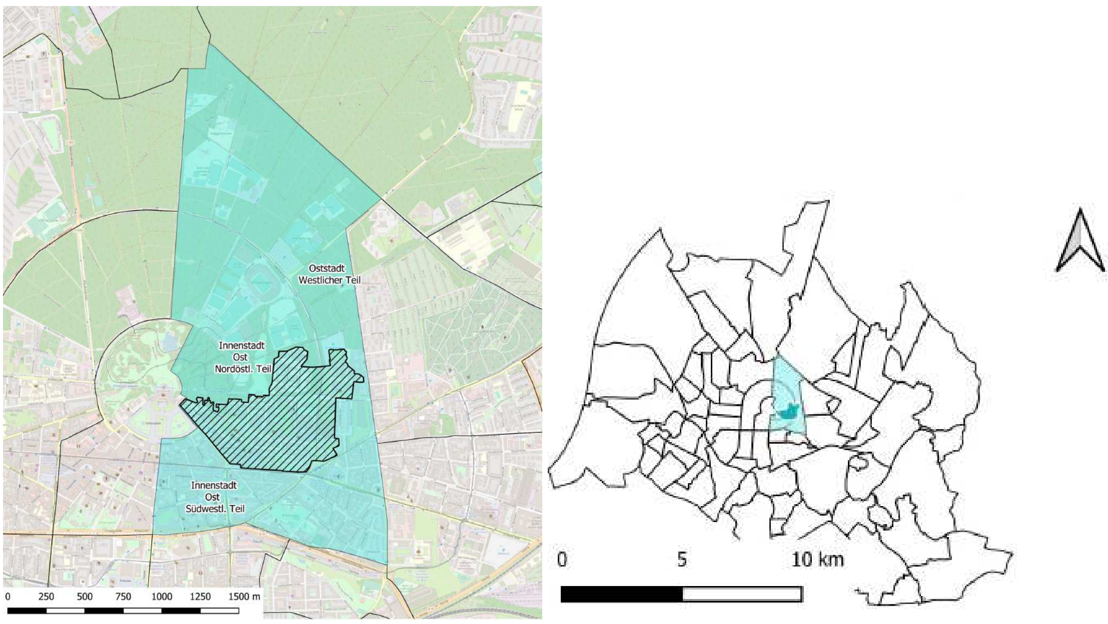

Abbildung 1: Lage des KIT Campus Süd im Stadtgebiet Karlsruhes (© Hanna Jäger). Datengrundlage: Stadt Karlsruhe 2016/17, Open Street Map

Die direkt an den Campus angrenzenden Stadtteile sind von dessen direkter Nachbarschaft über die Jahre geprägt worden. Neben einer hohen Zahl an Studierenden-WGs, Studierenden-Wohnheimen und der größten Dichte an Studentenverbindungen in Karlsruhe, finden sich in der direkten Nachbarschaft viele hochschulnahe Dienstleistungen, wie Copy-Shops, Reperaturläden für Fahrräder und studentische Gastronomieangebote sowie eine kleine Kneipenszene. Die Studierenden entwickelten sich über die Jahre zu einem wichtigen Teil des Stadtlebens in Karlsruhe. An den neun Hochschulen studieren heute rund 43.000 Studierende (STADT KARLSRUHE 2020). Sie sind mittlerweile maßgeblich prägend für die Altersstruktur und die Geschlechtsstruktur der jüngeren Altersgruppen der Fächerstadt, nicht zuletzt aufgrund der hohen männlichen Studierendenzahlen, die auf den technischen Schwerpunkt der Hochschule für Technik und Wirtschaft und des KIT zurückzuführen sind (STADT KARLSRUHE 2020). Mit 23.321 eingeschriebenen Studierenden im Wintersemester 2020/21 hat das KIT an dieser Entwicklung einen entscheidenden Anteil. Bedeutsam ist das KIT aber auch aufgrund seiner regionalen Strahlkraft als Arbeitgeber; im vergangenen Wintersemester beschäftigte das KIT 9.618 Mitarbeitende (KIT 2021).

2.2 Aktuelle Campus- und Stadtentwicklung in Karlsruhe

Jährlich zieht es tausende junge Menschen an Hochschulstandorte, um einem Studium nachzugehen oder in Forschungsinstitutionen zu arbeiten. Dies hat u.a. Auswirkungen auf den Wohnungsmarkt und das soziale Gefüge in den hochschulnahen Quartieren der Städte. Mit zunehmender Globalisierung und dem zunehmendem wirtschaftlichen Wettbewerb um Innovation und Kreativität rücken auch die wirtschaftlichen Effekte von Hochschulen im akademischen und öffentlichen Leben in den Fokus (GLÜCKLER 2018). Doch die Attraktivität eines Hochschulstandorts als Lebens- und Arbeitsmittelpunkt ist nicht an den Ruf einer Universität allein gebunden. Auch das städtische Leben und das Image der Stadt spielt bei diesen Entscheidungen eine nicht zu unterschätzende Rolle (beispielsweise KRAMER et al. 2014). Zur Attraktivitätssteigerung treten Universitäten nicht selten in den kommunalen Wettbewerb um Flächennutzung in der Stadtplanung und haben Interesse an Infrastrukturplanungen. Hochschulen und Forschungseinrichtungen sind andererseits auch wichtige Akteure der Wissensgenerierung für Städte. Wissenstransfer durch Auftragsforschung oder Förderung des Wissensaustauschs zwischen Stadt- und Wissensgesellschaft sind wichtige Bestandteile des akademischen und forschenden Lebens. Universitäten beteiligen sich dazu aktiv an politischen Prozessen der Entscheidungsfindung (vgl. GLÜCKLER 2018). Diese Prozesse bleiben für Einwohnende einer Stadt meist unsichtbar, wenn sie nicht eine direkte Beziehung zur Universität oder zur Stadtplanung haben. Anders sieht dies bei Baumaßnahmen aus, die beispielsweise rund um einen Campus diese Annäherung oder gar ‚Verknüpfung‘ von Campus und Stadt ‚sichtbar machen‘.

In Karlsruhe rückt die besondere Lage des innerstädtischen Campus des KIT und die direkte Nachbarschaft von Wissens- und Stadtgesellschaft bei allen jüngeren Campus- und Stadtentwicklungsprozessen in den Fokus. Südlich an den Campus angrenzend befindet sich der Stadtteil Innenstadt-Ost (Südwestlicher Teil), der seit 2017 städtebauliches Sanierungsgebiet ist. Hier steht, neben umfassenden Maßnahmen zur Verbesserung der Infrastruktur und des städtischen Lebens, die Verknüpfung von Campus und Stadt im Mittelpunkt. Vorschläge zur Gestaltung von neuen Eingangssituationen und grenzübergreifenden Maßnahmen zwischen Campusgelände und Wohngebiet sind bereits im Bau. Ähnliche Ziele finden sich im Masterplan des KIT von 2016. Auch hier ist als wichtiger Maßnahmenpunkt die Verbindung von Stadt und Wissenschaft aufgeführt (STADT KARLSRUHE 2017, KIT ZUKUNFTSCAMPUS 2016). Entlang der südlichen Campusgrenze wird beispielsweise eine neue U-Bahntrasse verlaufen, die die bisherige überlastete Straßenbahntrasse ersetzt und deren Linien die Innenstadt Karlsruhes mit dem gesamten Umland verknüpft. Durch die Verringerung des Verkehrsaufkommens zwischen Campus und Wohngebiet entstehen neue Freiflächen, die genutzt werden sollen, um u.a. die Eingangssituationen zum Campus attraktiver und sichtbarer zu gestalten. Ein erster Schritt in Richtung Öffnung stellt das ebenfalls hier entstehende neue Gebäude des KITs dar, dass mit einer offen gestalteten Erdgeschosszone künftig Wissens- und Stadtgesellschaft näher zusammenbringen soll. Ein weiteres solches Bauprojekt entsteht an der östlichen Campusgrenze, auch hier sind offen gestaltete Erdgeschosszonen vorgesehen, die die Stadtgesellschaft ansprechen sollen. Ein weiteres interessantes Projekt in diesem Zusammenhang wurde bereits 2018 von KIT und Stadt gemeinsam initiiert. Unter dem Slogan „Student*INNENstadt – Karlsruhe weiterdenken“ beteiligten sich 3.000 Studierende aller Karlsruher Hochschulen und entwickelten gemeinsam Ideen für eine studierendenfreundliche Stadt. Die hier zusammengetragenen Vorschläge und Wünsche sollen bei den weiteren Maßnahmen in der Stadtentwicklung Karlsruhes berücksichtigt werden (STADT KARLSRUHE

2019). Im Vordergrund steht dabei immer die Prämisse: Wissens- und Stadtgesellschaft einander näherbringen und den Austausch fördern. Um miteinander in einen Austausch zu gelangen ist es dabei hilfreich, sich auch in einem gemeinsamen Raum zu begegnen. Doch wie nah sind sich Wissens- und Stadtgesellschaft in Karlsruhe aktuell und welche Herausforderungen treten auf, wenn bauliche und infrastrukturelle Maßnahmen Raum verändern und auf das Handeln im Raum einwirken wollen?

3 INNERSTÄDTISCHER CAMPUS ≠ IN DER STADT

Der Campus Süd des KIT befindet sich zwar in Innenstadtlage, dennoch wirkt er nicht als Teil der Innenstadt, wie es beispielsweise der Marktplatz tut. Er wirkt eher wie ein besonderer Stadtraum, in dem andere Regeln gelten. Aus der Tradition der Universität heraus sind die Liegenschaften in der Obhut des Landes Baden-Württemberg und nicht der Stadt Karlsruhe. Das Gelände ist an vielen Eingängen bzw. Zufahrten als ‚Privatgelände' gekennzeichnet. Am Zugang des Campus Süd ändert dieser Sachverhalt erstmal nichts, denn das Gelände ist, anders als der Campus Nord, nicht umzäunt und das Gelände ist frei zugänglich. Im Prinzip hat jeder die Möglichkeit, sich auf das Campusgelände zu begeben und sich dort aufzuhalten. Zwar finden sich entlang der Campusgrenzen noch Reste alter Grenzzäune, Hecken und Tore, dennoch ist der Zugang lediglich für den Autoverkehr tagsüber durch Zufahrtsschranken reglementiert. Der Zugang zu Fuß oder via Fahrrad ist an vielen Stellen rings um den Campus problemlos möglich. Dennoch wirkt der Campus als (Stadt-)Raum aufgrund seiner Anlage, der Wahrnehmung der Gebäudestruktur und der überwiegenden akademischen Nutzung auf viele Menschen ausgrenzend.

In der Humangeographie wird der Wirkung eines Raumes auf den Menschen und dem Wirken des Menschen im Raum eine große Bedeutung beigemessen. Raum und Handlung beeinflussen sich gegenseitig (z.B. WERLEN 2010). ‚Räume' entstehen nach dieser Annahme erst durch die Wirkung einer gebauten Umwelt und den daraus resultierenden menschlichen Aktionen in dieser. Übertragen auf den Campus bedeutet dies, der Campus als Konzentration von Gebäuden forschungs- und lehrorientierter Nutzungen wird erst zum Raum ‚Campus' durch die Menschen, die diesen Ort primär zum Forschen und Lehren aufsuchen und entsprechenden Tätigkeiten nachgehen. Der Raum wird dabei den Nutzungen ständig angepasst und verändert sich nach den Bedürfnissen der dort Tätigen. Das Zusammenspiel von Gebäudestruktur und Nutzungsprofil eines Campus lässt den Raum so als geschlossenen Ort wirken, der sich gegenüber anderen Stadträumen, wie beispielsweise einem Marktplatz, der für eine offene Kommunikation und einen Austausch der Menschen gedacht und angelegt ist, deutlich unterscheidet und sich demzufolge von anderen städtischen, öffentlichen Räumen abgrenzt. Die Gestalt von Räumen legt bestimmte Nutzungen nahe, fördert oder verhindert sie (vgl. STURM 2018). Dies zeigt sich am Campus Süd des KIT beispielsweise durch das Nicht-Vorhandensein eines öffentlichen Cafés oder Spielplatzes sowie Zugangsbeschränkungen in der Cafeteria, Beschränkung in der Ausleihe und dem Angebot der Bibliothek. Mit dem Ausschluss öffentlicher Nutzungen werden damit folglich auch Personen ausgeschlossen. Diese Beobachtung macht auch STURM im Versuch, halböffentliche Räume zu beschreiben. Ein Merkmal halböffentlicher Räume kann die Beschränkung auf einen bestimmten sozialen Status der Nutzenden darstellen. Diese (Selbst-)Selektion im Alltag wird als selbstverständlich angesehen und entweder kaum wahrgenommen oder bewusst akzeptiert, um Konflikte zu vermeiden (EBD.). Diese Beobachtung und Erklärung kann auch auf das Campusgelände im Stadtraum übertragen werden. Somit ist der innerstädtische Campus zwar durch seine Innenstadtlage öffentlich zugänglich, seine Eigenschaften lassen ihn doch eher als halböffentlichen, einer bestimmten Nutzendengruppe zugeschriebenen Ort erscheinen. Diese Herausforderung stellt sich anschließend bei der Verknüpfung von öffentlichem und halböffentlichem Stadtraum. Doch die Situation bzw. der Alltag auf dem Campus hat sich verändert.

Im Sommer 2021 befindet sich das KIT bereits im dritten Online-Semester. Seit März 2020 sind die meisten Mitarbeitenden im Home-Office und der Lehrbetrieb findet überwiegend im Online-Format statt. Die größte Nutzergruppe des Campusgeländes sind die Studierenden. Viele haben ihr Studium im vergangenen Jahr jedoch als ‚Fernstudium' begonnen, da durch die fehlende Präsenz auf dem Campus die Notwendigkeit eines Wohnortwechsels in vielen Fällen nicht bestand. Dies hatte direkten Einfluss auf das städtische Leben. Mit ca. 4.000 weniger Einwohnern im ersten Quartal 2021 gegenüber dem ersten Quartal 2020 hat sich die Corona-Pandemie vor allem auf den Zuzug von jungen Studierenden deutlich bemerkbar gemacht (STADT KARLSRUHE 2021). Nach einem Jahr Corona-Pandemie konnte sich die Hochschullehre auf das Online-Format umstellen und es werden sich in Zukunft einige Online-Formate durchsetzen, sodass es nicht mehr für jede Lehrveranstaltung notwendig sein wird, am Hochschulstandort – sprich auf dem Campus vor Ort – zu sein, um dem Studium nachzugehen. Doch welche Potenziale stecken in einem Campusgelände für andere Nutzergruppen? Wie wird der innerstädtische Campus von Nicht-Campus-Angehörigen genutzt und wer nutzt ihn v.a. während der Corona-Pandemie, in der das akademische Leben weitestgehend vom Campus gewichen ist und somit die größte Nutzendengruppe weggefallen ist? Verändert sich die Wahrnehmung des Campus? Wie haben sich die Maßnahmen zur Eindämmung des Corona-Virus auf das Leben auf dem Campus ausgewirkt und welche Konsequenzen können aus dieser Erfahrung für die zukünftige Stadt- und Campusentwicklung gezogen werden?

4 MASSNAHMEN ZUR EINDÄMMUNG DER VERBREITUNG DES CORONAVIRUS IN KARLSRUHE MIT FOKUS AUF AUSWIRKUNGEN AUF DIE CAMPUSNUTZUNG

Die Maßnahmen zur Eindämmung der Corona-Pandemie haben das öffentliche Bewegen von Menschen im Raum stark beeinflusst, davon blieb auch der halböffentliche Raum des Campusgeländes nicht unberührt. Im Folgenden soll daher ein kurzer Überblick gegeben werden, welche Maßnahmen v.a. den Zugang und den Aufenthalt im (halb-)öffentlichen Raum, wie es das Campus-Gelände darstellt, verändert haben.

4.1 Maßnahmenüberblick der Stadt Karlsruhe seit März 2020

Zum 18.03.2020 trat die erste Landesverordnung Corona in Baden-Württemberg (Corona VO BaWü) in Kraft, die u.a. folgende Reglementierungen für den öffentlichen Raum vorsah:

Es galt ab 23.03.2020 eine Kontaktbeschränkung im öffentlichen Raum. Zunächst durften sich nur noch zwei Haushalte bzw. nicht mehr als zehn Personen im Freien treffen. Mit dieser Kontaktbeschränkung wurden Spiel- und Sportstätten geschlossen und Gruppenansammlungen – wie beispielsweise eine Studierendengruppe auf dem Campus oder in öffentlichen Grün- und Parkanlagen – untersagt.

Der Betrieb von öffentlichen (kulturellen) sowie religiösen Einrichtungen, des Einzelhandels und der Gastronomie wurden ebenfalls verboten. Vor allem der Wegfall von Außengastronomie führte in Karlsruhe zu leeren öffentlichen Plätzen. Auch die Wochenmärkte und öffentliche Veranstaltungen im Freien mussten abgesagt werden.

Mit Schließung des Schloss- und des Zoologischen Stadtgartens fielen wichtige öffentliche Naherholungsflächen im Stadtraum auf bestimmte Zeit weg. Hinzu kam wenig später ein Betretungsverbot von weiteren öffentlichen Plätzen, wie beispielsweise Aussichtsplattformen oder andere Stellen, an denen es vermehrt zu größeren Menschenansammlungen aufgrund touristischer Zwecke kommen kann.

Somit wurde die Bewegung im öffentlichen Raum stark eingeschränkt. Zunehmend konnte beobachtet werden, wie die Stadtbewohnenden auf andere innerstädtische bzw. innenstadtnahe Flächen auswichen. Der Hardtwald wurde als Naherholungsgebiet beliebter denn je. In einer Meldung vom 28.05.2020 verkündete die Stadt Karlsruhe, dass der „Stadtwald bei Erholungssuchenden jetzt besonders gefragt“ sei (https://corona.karlsruhe.de/). Die Menschen wichen auf andere Flächen aus. Zunehmend konnten auch auf dem Campus vermehrt ‚Spaziergänger‘ beobachtet werden.

Anfang Mai 2020 wurden dann mit Einführung einer (Alltags-)Maskenpflicht erste Reglementierungen wieder entschärft. Sportstätten, Spielplätze, Ausstellungen und Zoos wurden wieder geöffnet und im weiteren Verlauf öffneten allmählich auch Gaststätten und Sportanlagen wieder. Diese neuen Verordnungen sahen vielerorts Maskenpflicht vor, entsprechende Hygienekonzepte mit den sog. A-H-A-Regeln und hoben das Betretungsverbot im öffentlichen Raum wieder auf, sodass öffentliche Stadträume, wie der Botanische Garten und Schlossgarten, wieder für Passierende zugänglich wurde. Nachdem über den Sommer die Bewegung im öffentlichen Raum nicht mehr durch Betretungsverbote eingeschränkt wurde, folgte ab dem 19.10.2020 die Maskenpflicht im öffentlichen Raum, wenn der Mindestabstand nicht eingehalten werden kann (beispielsweise Innenstadt, Schlosspark, etc.). Anfang Dezember erließ die Stadt Karlsruhe die nächtliche Ausgangssperre. Von 23.03.2021 bis 22.05.2020 war in Karlsruhe die Bundesnotbremse in Kraft. Seitdem sind die Fortbewegung und die Möglichkeiten im öffentlichen Raum wieder gelockert worden.

4.2 Auswirkungen der Maßnahmen auf den Hochschulbetrieb und das Campusleben

Bereits am 13.03.2020 informierte das Präsidium des KITs alle Studierenden und Mitarbeitenden, dass „[m]it sofortiger Wirkung […] am KIT alle Veranstaltungen vom 17.03. bis einschließlich 19.04.2020

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

abgesagt [werden]“ (E-Mail des Präsidiums vom 13.03.2020). Somit wurde der Einstellung des Studienbetriebs an Hochschulen aus der ersten Corona VO BaWü entsprochen. Dies betraf jegliche Lehrveranstaltungen, die laufende Prüfungsphase und sonstige Veranstaltungen, die in Präsenz geplant waren oder gerade stattfanden. Online-Formate konnten weiter bestehen. Sofern Veranstaltungen nicht zur Aufrechterhaltung des Betriebs am KIT erforderlich waren, wurde das Campusleben vom Campus verbannt. Der Vizepräsident für Lehre und akademische Angelegenheiten des KIT bat die Studierenden eindringlich darum, den Campus nicht zum Besuch von Lehrveranstaltungen oder zum Lernen zu betreten. Mit dem Ausschluss der Campus-Angehörigen vom selbigem, wurden auch alle Einrichtungen, wie Bibliothek, Cafeterien, die Mensa und das Studentenwerk, bis auf Weiteres geschlossen.

Von Mai bis Juli 2020 kehrten die ersten Studierenden während der ‚Sonderprüfungsphase‘ auf den Campus zurück. Auch Laborpraktika oder andere, wichtige Präsenzveranstaltungen, konnten mit der Einhaltung entsprechender Hygienekonzepte stattfinden und auch die Mensa und Cafeterien boten Essen zum Mitnehmen an. Dies bewirkte, dass sich wieder mehr Studierende und Mitarbeitende auf dem Campus fortbewegten und die Freiflächen nutzten. Da jedoch auch das folgende Wintersemester im Online-Format startete, ist das Campusleben im Mai 2021 noch nicht vollständig zurückgekehrt. Das KIT setzt seit März 2020 immer noch verstärkt auf eine Home-Office-Empfehlung für die Beschäftigten. Der Studienbetrieb befindet sich weiterhin überwiegend im digitalen Format. Anders als für den öffentlichen städtischen Raum hatte das Einsetzen der bundesweiten Notbremse Ende März für die Campusnutzung keine weiteren Auswirkungen. Nach der aktuellen Corona VO BaWü ist der Präsenz-Studienbetrieb der Hochschulen immer noch ausgesetzt, Ausnahmen werden zunehmend ausgeweitet (beispielsweise Laborpraktika, wichtige mündliche/schriftliche Klausuren etc.).

5 STUDIENDESIGN

Hatte dieses Aussetzen der überwiegend studentischen Nutzung vom Campus bereits einen Effekt auf die Nutzung, Bedeutung und Wahrnehmung des Campusgeländes bei den Nutzenden? Mit dieser Frage befasste sich im Wintersemester 2020/2021 und Sommersemester 2021 eine Studierendengruppe am Institut für Geographie und Geoökologie des KIT. Innerhalb des Studiengangs B.Ed. Geographie absolvieren die Studierenden in ihrem fünften und sechsten Fachsemester ein ‚Methodenorientiertes Projektseminar‘. Im Rahmen dieses semesterübergreifenden Seminars werden sie an das wissenschaftliche Arbeiten herangeführt, um so auf das Verfassen ihrer eigenen Qualifikationsarbeit vorbereitet zu werden. Das Seminar entstand aus dem Projekt LehreForschung heraus, das über mehrere Jahre vom Bundesministerium für Bildung und Forschung gefördert wurde. Die Inhalte des Projektseminars werden mit jeweils laufenden Projekten aus der Arbeitsgruppe Humangeographie des Instituts verknüpft, um Studierenden die Möglichkeit zu geben, Einblicke in aktuelle Forschungsprozesse zu erhalten. Lernziele des Seminars umfassen das wissenschaftliche Arbeiten mithilfe eigener Fragestellungen und einer eigenen empirischen Untersuchung. Für das vorgestellte Semester befassten sich die Studierenden mit der Fragestellung: ‚Campus in der Stadt: #Elfenbeinturm oder #Stadtviertel?‘ und untersuchten die Aspekte Wohnen, Verkehr, Arbeit und Bildung, Einkaufen und Versorgen sowie Kultur und Freizeit und die damit verbundene Verknüpfung zwischen Campus und Stadt in Karlsruhe. Darüber hinaus wurde auch gefragt, inwieweit die Corona-Pandemie die Nutzung und Wahrnehmung des Campus verändert. Um die aktuelle Campusnutzung und Bedeutung aufzunehmen, wurd eine mündliche Befragung auf dem Gelände selbst gewählt. Die Befragung fand zwischen dem 01.03. und 21.03.2021 mithilfe eines gemeinsam im Seminar entwickelten, standardisierten Fragebogens mit überwiegend geschlossenen Fragen statt. Die Auswahl der befragten Personen erfolgte zufällig. Aufgrund des sehr eingeschränkten Studien- und Arbeitsbetriebs auf dem Campus gestaltete sich die Erhebungsphase als schwierig. Die Studierenden befragten ausschließlich Studierende und Mitarbeitende auf dem Gelände. Zeitgleich startete die schriftliche Anwohnendenbefragung des Promotionsprojektes in die Feldphase, aus dem die Idee und die Betreuung des Seminars stammt. Im folgenden werden überwiegend die Ergebnisse der Studierendenbefragung diskutiert, die mit ersten Ergebnissen der laufenden Promotion ergänzt werden.

6 NUTZUNG DES CAMPUSGELÄNDES SEIT MÄRZ 2020

Im folgenden werden die Ergebnisse der Studierenden- und Mitarbeitendenbefragung aus dem Seminar vorgestellt und mit ersten Ergebnissen aus dem laufenden Promotionsprojekt ergänzt.

6.1 Zugang und Fortbewegung zum und auf dem Campus Süd

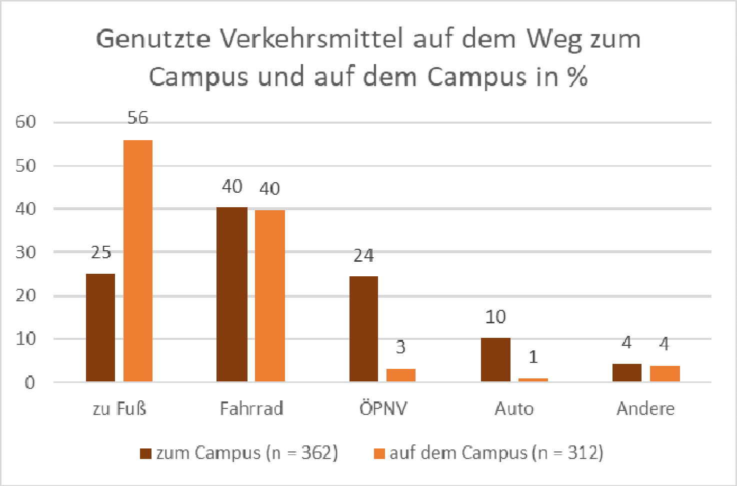

Abbildung 2: Genutzte Verkehrsmittel auf dem Weg zum und auf dem Campus (© Jung, Schuhbauer)

Die innerstädtische Lage des Campusgeländes lässt eine gute Erreichbarkeit aus den umliegenden Stadtteilen erwarten. Die befragten Personen gaben dazu Auskunft, wie sie sich zum und auf dem Campusgelände fortbewegen (ABB. 2). Dabei fiel auf, dass die Fortbewegung auf dem Campus sehr entschleunigt ist. Einen Beitrag dazu könnte der beruhigte Autoverkehr darstellen. Tagsüber ist die Zufahrt mittels Schranke reglementiert und auf dem Campus gilt überwiegend ein Tempolimit auf 30 km/h bzw. Schrittgeschwindigkeit (10 km/h). Die meisten befragten Personen gelangen mit dem Fahrrad zum Campus und bewegen sich mittels Fahrrad auf dem Campus fort (40 %, 146 Nennungen ‚zum Campus' und 124 ‚auf dem Campus'). Auf dem Campus bewegen sich über die Hälfte der befragten Personen zu Fuß fort (56 %, 175 Nennungen). Dieser hohe Anteil setzt sich aus den ankommenden PKW-Fahrer und ÖPNV-Nutzern zusammen, die auf dem Campus die Strecken zu Fuß zurücklegen. Der hohe Anteil an nachhaltiger Fortbewegung, mittels Fahrrad oder zu Fuß, spricht für einen sehr ruhigen Verkehrsbereich. Diese Beruhigung wirkt sich positiv auf den nachhaltigen Verkehr auf dem Campusgelände aus und kann einen wichtigen Beitrag zum Naherholungsaspekt des Geländes leisten.

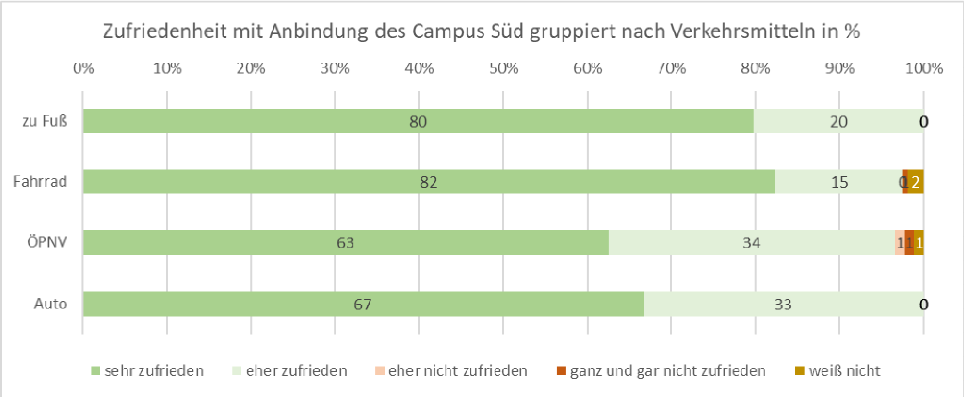

Abbildung 3: Zufriedenheit mit Anbindung des Campus gruppiert nach Verkehrsmitteln

Die Erreichbarkeit des Campusgeländes wird von allen befragten Personen mit unterschiedlichen Verkehrsmitteln als sehr zufriedenstellend bewertet (ABB. 3). Egal ob zu Fuß, mit dem Fahrrad, dem ÖPNV oder mit dem Auto – das Campusgelände ist in Karlsruhe sehr gut erreichbar und gut an Verkehrsnetze angebunden. Im Hinblick auf die Maßnahmen zur Verknüpfung von Stadt und Campus ist diese Wahrnehmung der Nutzenden sehr wichtig, denn Sie zeigt, dass es nicht nur theoretisch möglich ist, auf das Campusgelände zu gelangen, sondern dass die Anbindung auch sehr zufriedenstellend ist. Es gibt keine verkehrstechnischen oder infrastrukturellen Maßnahmen, die bzgl. der Erreichbarkeit des Geländes getroffen werden müssten.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

6.2 Campusaufenthalt der Studierenden und Mitarbeitenden

Der Aspekt des ‚Erholungsortes' verstärkt sich mit Blick auf die Freizeitaktivitäten der befragten Studierenden und Mitarbeitenden auf dem Campusgelände. Von insgesamt 313 Nennungen auf die Frage ‚zu welchen Zwecken die Freiflächen des Campus genutzt werden', antworteten 16 % (50) zum ‚Entspannen, Chillen, Erholen' (siehe ABB. 4). 9,3 % (29) nannten explizit das ‚Spazieren' gehen. Diese Aktivitäten werden wahrscheinlich v.a. zu Pausenzeiten, sowie vor und nach Studien- und Arbeitsbetrieb ausgeführt. V.a. der Austausch und das Aufeinandertreffen von Freunden, Kommilitonen und die gemeinsam verbrachte Zeit ist hier in allen genannten Kategorien anzutreffen. Sie alle zeichnen sich durch die soziale Interaktion mit Mitmenschen aus.

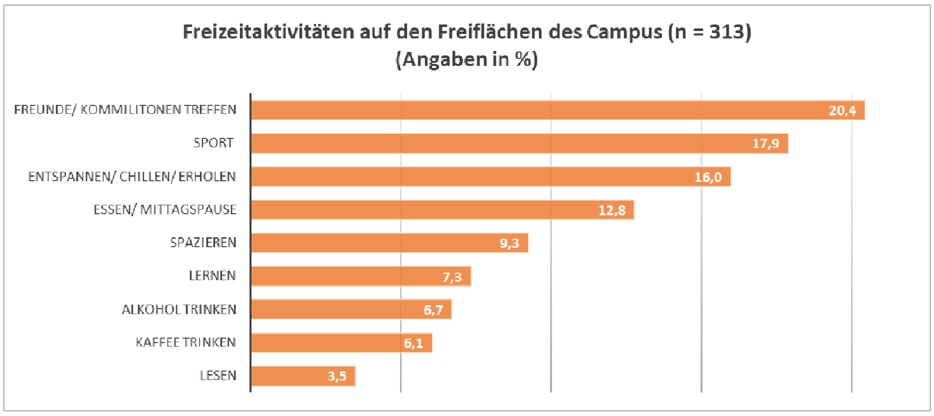

Abbildung 4: Freizeitaktivitäten auf den Freiflächen des Campus (© Heller, Hellriegel)

Die Freiflächen des Campusgeländes scheinen diesen Austausch in vielfältiger Form zu unterstützen. 20,4 % (64) treffen sich auf den Freiflächen v.a. mit Freunden oder Komm-ilitonen. Dies geschieht womöglich ebenfalls überwiegend während der täglichen Studien- und Arbeitszeit, wobei die Nennung von ‚Alkohol trinken' (6,7 %, 21) durchaus auch auf eine Nutzung des Campusgeländes in den Abendstunden schließen lässt. Anhand der hier getätigten Nennungen ist auffällig, dass sich die Freizeitaktivitäten auf den Freiflächen des Campus nicht wesentlich von anderen öffentlichen städtischen Räumen, wie beispielsweise einer Grün- oder Parkanlage, unterscheiden. Zum Aufenthalt im Tagesverlauf waren Mehrfachnennungen zu den gegebenen Kategorien aus ABB. 5 möglich. Daraus wird ersichtlich, dass 78 % der befragten Personen (341 Nennungen) sich üblicherweise am Vor- und Nachmittag auf dem Campus aufhalten. Dies deckt sich mit der gewöhnlichen Arbeits- und Studienzeit auf dem Gelände. Da hier die Formulierung ‚üblicherweise' in der Fragestellung gewählt wurde, ist davon auszugehen, dass sich die Antwort auf den regulären Campusbetrieb bezieht und nicht zwingend auf die aktuelle Nutzung.

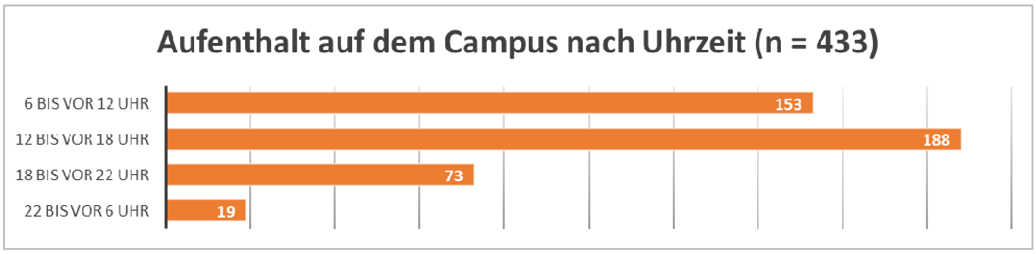

Abbildung 5:Aufenthalt auf dem Campus im Tagesverlauf

Der geringe Anteil an Aufenthalten in den Abend- und Nachtstunden kann hier zum einen mit der geringen Aktivität in den Abendstunden auf dem Campus erklärt werden. Der reguläre Studien- und Arbeitsbetrieb endet größtenteils um 18 Uhr auf dem Campus. Einige kulturelle Veranstaltungen sorgen während des Semesters dafür, dass auch abends Feste oder Veranstaltungen stattfinden und die Menschen sich hier aufhalten. Besonders während des Sommersemesters finden viele Festivitäten der Studierenden und Fachschaften statt, die viele Menschen auf den Campus locken. So auch das Unifest, das von Stadt- wie Wissensgesellschaft über mehrere Tage im Sommer gerne besucht wird und bereits auf eine lange Tradition zurückschauen kann. Im Wintersemester finden viele Veranstaltungen in den Gebäuden statt und haben nach außen weniger Präsenz. Nur 17 % (73 Nennungen) der befragten Personen gaben an, sich abends auf dem Gelände aufzuhalten und lediglich 4 % (19 Nennungen), dass sie dies nachts tun würden. Inwieweit diese

Wahrnehmung durch die Corona-Pandemie getrübt wurde, kann sich nicht so leicht feststellen lassen. Durch die Maßnahmen zur Eindämmung des Corona-Virus sind viele Festivitäten bereits im vergangenen Sommer abgesagt worden. Durch die geringe Aktivitäte auf dem Campus infolgedessen kann es durchaus zu einer geringeren Aufenthaltsdauer zur Zeit der Corona-Pandemie kommen, als dies zu einem früheren Zeitpunkt festzustellen wäre. Ein weiterer Punkt der zu einem geringeren Aufenthalt in den Abend- und Nachtstunden führen könnte, ist die spärliche Ausleuchtung der Freiflächen auf dem Campus. Dennoch ist an dieser Stelle nochmal auf die besondere Situation während der Corona-Pandemie hinzuweisen. Die wenigen Studierenden und Mitarbeitenden, die im Rahmen der Befragung auf dem Campusgelände angetroffen wurden, halten sich derzeit überwiegend tagsüber auf dem Gelände auf. Die im Titel dieses Beitrags erwähnte ‚gähnende Leere' zeigt sich hier in der generell geringen Nutzung des Campusgeländes derzeit von Studierenden und Mitarbeitenden und zeigt sich v.a. in der Nutzung des Geländes im Tagesverlauf.

6.3 Wahrnehmung des Campus aus Sicht der Anwohnenden

Abbildung 6: Assoziationen zum Campus Süd aus Sicht der Anwohnenden

Und wie empfinden es die Anwohnenden? In Kapitel 3 wurde bereits auf die Wirkung eines Raumes auf den Menschen und die daraus resultierenden Handlungen eingegangen. Nun stellt sich für diesen halböffentlichen Raum, der in Innenstadtlage für jeden zugänglich und wie bereits gezeigt sehr gut erreichbar ist, die Frage, wie wird er von außen wahrgenommen? Die Wahrnehmung lässt sich gut mithilfe von Assoziationen zu einem bestimmten Raum darstellen. Nachstehende Wortwolke (ABB. 6) zeigt die zusammengefassten Assoziationen der befragten Anwohnenden. Je häufiger ein Begriff dabei genannt wurde, desto größer erscheint er in der Abbildung. Die Frage lautete: „Was fällt Ihnen als Erstes ein, wenn Sie an den Campus Süd denken"?. Auf den ersten Blick fallen typische studentische Zuschreibungen auf. Daneben fällt auf, dass der Campus als ‚grün', ‚groß' und ‚weitläufig' wahrgenommen wird, der viele zur Tätigkeit des ‚Spazieren gehen' einzuladen scheint. Diese Form der Naherholung taucht sehr präsent in der Wortwolke auf. Durch die Mehrfachnennung der eben genannten Begriffe rund um das ‚Spazieren gehen' kann darauf geschlossen werden, dass viele Anwohnende den Campus neben dem reinen Hochschulstandort auch als Naherholungsort wahrnehmen und ihn beispielsweise für Spaziergänge in ihrer Freizeit aufsuchen und nutzen. Es wird im weiteren Verlauf des Promotionsprojektes noch herauszufinden sein, inwieweit sich die Wahrnehmung der ‚gähnenden Leere' zur Zeit der Corona-Pandemie auch auf die Anwohnenden übertragen hat.

6.4 Einfluss der Corona-Pandemie auf den Aufenthalt der Anwohnenden auf dem Campus

Die ersten Auswertungen zeigen, dass es tatsächlich seit März 2020 zu einer Veränderung der Nutzung des Campus gegeben hat. Die umliegenden Anwohnenden des Campusgeländes wurden im Rahmen der Anwohnendenbefragung dazu befragt, ob sich ihr Aufenthalt auf dem Campus seit März 2020 verändert habe. Durch die Schließung öffentlicher Einrichtungen und das Betretungsverbot öffentlicher Anlagen und die sehr gute Anbindung des großen Campusgeländes liegt die Vermutung nahe, dass viele auf diese Fläche beispielsweise zum Spazieren gehen ausgewichen sind und so die Nutzungsintensität höher sein könnte, als noch vor der Pandemie. Von 399 Anwohnenden gaben 6 % (25) an, tatsächlich seit der Corona-Pandemie häufiger auf dem Campusgelände unterwegs zu sein. Hier könnte die Wertschätzung und die Wahrnehmung des Campus sich im letzten Jahr auch verändert haben. Auch interessant ist, dass 41 % (162) der Anwohnenden angaben, dass sich ihr Campusaufenthalt nicht verändert habe. Diese gehen entweder gleich oft oder gleich selten bzw. nie auf den Campus. Diese können auch wiederum in diejenigen aufgeteilt werden, die den Campus ohnehin schon häufig besuchen oder das Gelände nutzen und die, die den Campus nicht so regelmäßig nutzen. Die 53 % (212) der Anwohnenden, die den Campus seit Beginn der Corona-Pandemie seltener nutzen, sind mit hoher Wahrscheinlichkeit anwohnende Studierende oder Mitarbeitende, die das Studium und die Arbeit seitdem im Home-Office bewältigen. Es könnte aber auch auf die Beschränkungen im öffentlichen Raum zurückzuführen sein, sodass zugängliche ‚Stadträume' von den Anwohnenden nicht mehr so häufig betreten wurden und dies das Gelände des Campus in der Wahrnehmung als ‚öffentlicher Raum' einschloss.

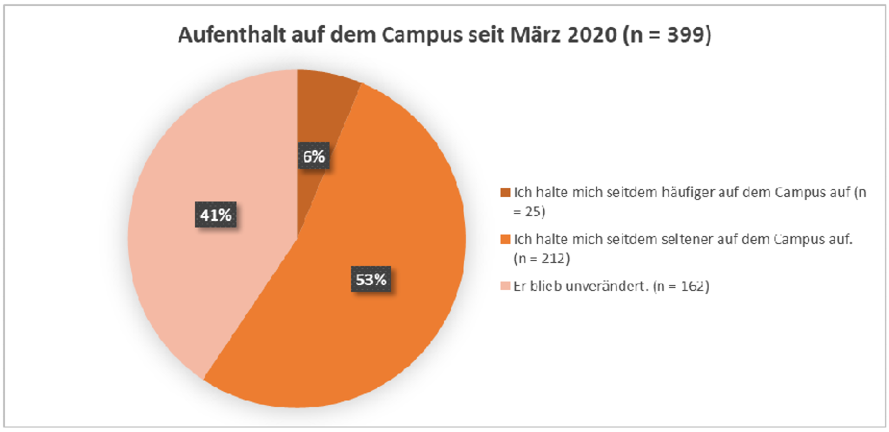

Abbildung 7: Aufenthalt auf dem Campus seit März 2020 (Anwohnende)

7 FAZIT UND AUSBLICK

Die Ergebnisse der Seminarstudie haben gezeigt, dass Campus-Angehörige wie Anwohnende das Campusgelände als geschätzten Naherholungsraum wahrnehmen und die Freiflächen überwiegend für soziale Aktivitäten des Austauschs nutzen. Dieses hohe Potenzial zur Ausübung sozialer Aktivitäten auf den Freiflächen des Campus kann in der zukünftigen Campusentwicklung weiter ausgeschöpft werden. Der Campus Süd ist bereits jetzt mit verschiedenen Verkehrsmitteln sehr gut aus allen Stadtteilen der Stadt Karlsruhe erreichbar und die Art der Anbindung bzw. die Wege zum Campus sind sehr zufriedenstellend. Die Verkehrsberuhigung auf dem Campusgelände durch die Reglementierung der Zufahrt mit dem PKW zeigt sich hier ebenfalls als eine zu fördernde Maßnahme, die den Campus als Naherholungsfläche attraktiv macht. Diese hohe Standortqualität des Campus als innerstädtischer Erholungsraum könnte in Zukunft noch gesteigert werden durch das Beachten der Bedürfnisse der Nutzendengruppe der Spaziergehenden, da sich die Hauptnutzungszeit, v.a. derzeit im Verlauf der Corona-Pandemie, überwiegend auf den Tag bezieht. Die Einrichtung von Ruhebänken, öffentlichen Toiletten oder beispielsweise Bücherschränken könnte zu einer höheren Verweildauer auf dem Gelände führen. Hier könnten dann weiter entsprechende Angebote das Interesse und die Aufmerksamkeit der städtischen Gesellschaft auf wissenschaftliche Themen und Forschungen gelenkt und ein Austausch zwischen Stadt und Wissenschaft initiiert werden. Die rein hochschulaffinen Nutzungen befinden sich hier erst hinter den Gebäudewänden, die für die Öffentlichkeit nicht frei zugänglich sind. Die neu entstehenden Gebäude entlang der Campusgrenzen könnten mit ihren öffentlich ausgerichteten Erdgeschosszonen dafür sorgen, die Grenze zwischen Campus und Stadt, nicht an den Gebäudewänden enden zu lassen. Hier entsteht neues Potenzial, Raum für Synergieeffekte und Austausch. Dennoch gleicht das Campusgelände derzeit eher einer „Wüste", als dass der im Beitragstitel aufgerufene ‚beliebter Park' in der Befragung ersichtlich wurde. Es muss sich zeigen, ob die leicht erhöhte Nutzung und Nachfrage des Geländes als innerstädtischer Naherholungsraum sich nach der Corona-Pandemie durchsetzen wird. Es wird angenommen, dass die ‚gähnende Leere' auf dem Campus durch das Fehlen der Studierenden und Mitarbeitenden dazu einen hohen Beitrag geleistet hat. Kehren diese wieder auf den Campus zurück, ist abzuwarten, ob sich der Effekt der erhöhten Nachfrage nachhaltig etabliert und sich das Potenzial des nachgefragten innerstädtischen Nacherholungsraumes weiter ausschöpfen lässt. Dabei stellt sich jedoch für die Zukunft die Frage: Wie offen sollte ein solcher Campus tatsächlich gestaltet werden? Die Vorteile eines halböffentlichen Raumes und die Idee der Campusanlage sollten bedacht werden. Sie fördern eine größere Ruhe, Kontemplation und Freiheit der Planung für die Campusentwicklung. Es ist daher zwingend notwendig den Ist-Zustand der jeweiligen Campusnutzung am Standort zu evaluieren, um für die jeweilige Situation die geeigneten Maßnahmen zur Verknüpfung von Stadt und Campus zu eruieren.

(Prof. Khaled Elhaggla, Alexandria University, khaledhagla@hotmail.com)

1 ABSTRACT

In the past half-century, researchers started paying attention to enhancing the performance of urban spaces. Their perception of performance comprised urban climate changes, space synthesis, economic performance, and enhancing the quality of life in spaces. However, it has been agreed that Good Governance(GG) is the key to achieving any of the previously mentioned enhancement projects. Good Governance(GG) pillars ensures the participation of the public.

Public participation is a cornerstone in any planning process. Nevertheless, the way in which the participation practices are accomplished guarantees its effectiveness as a planning tool. In these regards, Good Governance (GG) stands as a keyword. Having good governance allows citizens to participate freely in development projects, ensuring the deep fulfillment of users' needs, and the efficient use of city resources and assets.

This paper proposes a framework for effective public participation based on Good Governance (GG) understandings. Considering the implementation challenges in different conditions, it focuses on the third world countries and Egypt in particular. It identifies the keys to a successful participation process by correlating effective participation practices to the levels of participation, types of stakeholders, the stages of urban development, the city systems, and the participation process. Finally, this paper validates the proposed framework by analyzing the Elkhaledin garden re-development project, one of the city center revitalization projects in the city of Alexandria, Egypt.

Keywords: stakeholders, participation, third world countries, urban development, governance

2 INTRODUCTION

Many cases considers governance as a separate element from governments, while in others, governance is equalized with the government. Therefore, a number of definitions were proposed to meet these interlocking interpretations. Keefer describes governance as no Sharpe definition would provide a convenient interpretation of the process (Peter Keefer, 2009).Weiss, on the other hand, lists seven different definitions of governance(Renée E. Weiss, 2000). The OECD compiles another seventeen definitions(OECD, 2009) describing governance as a political authority that exercises control over society. Not only do definitions vary across organizations, but they also vary within organizations. Even the World Bank has several definitions proposed.

A number of the above mentioned definitions include three words that demonstrate the governance system; Process, Power, and Management of the common affairs of a community (or a country, society, or nation). These numerous definitions suggest different criteria and standards against which the quality of governance can be assessed(Tosics, 2011). They claim that the presence of governance in a society is never enough to manage public affairs, good governance (GG) is a crucial element in the process. Good governance(GG) is a modern concept that does not only comprises the control of power and politics to control the public but incorporates all the authorities available(Rotberg, 2014). This new concept lies on three main pillars; Accountability, Participation, and Transparency.

Among the previously discussed pillars, public participation is considered the most accurate and illegible one to be used in such situations. Participation is widely considered to improve the quality and effectiveness of decision-making(Enserink, Witteveen, & Lie, 2009). It is used in many life aspects, from environmental development over urban and regional planning to general polities. Although its importance remains massive, it's not widely popular to use in most countries. Public participation alone does not ensure good governance (GG) practice. Even though it faces some serious troubles and challenges, the best way to achieve its goals is by ensuring the effectiveness of the public participation process. Integrating Demand for Good Governance (DFGG) mechanisms into projects involves setting up systems to ensure that beneficiaries have a greater voice in planning and that the project is downwardly accountable and responsive to their needs. It can be initiated and supported by government, citizens, or both.(Enserink et al., 2009).

This paper aims to study the effective public participation process in urban development projects, several researcher's proposals are analysed leading to the formulation of a framework that facilitates the flow of the process. This framework encompass four stages of the planning process, however, only the first stage will be tested in this paper by comparing its results with an urban development case study in Alexandria, Egypt that took place two years ago and the project reopening was ten months ago.

3 CONCEPTUAL FRAMEWORK METHODOLOGY FOR EFFECTIVE PUBLIC PARTICIPATION FRAMEWORK (EPPF)

This section introduces the proposal's theoretical framework. The framework decends from a3

combination of the concept of Hudson Smith and Wilcox. It includes four main elements; the levels of participation, stakeholders participating, communication tool, and stage of urban planning. The results produced four main participation templets for each of the stages of the planning.

3.1 Concept of the framework

Hudson Smith designed a matrix that links the levels of participation, forms of communications, addresses, and the communication tool(Hudson-smith, Evans, Batty, & Batty, 2002). Wilcox, a researcher, and planner submitted a matrix between the levels of participation, the phases of participation, and the stakeholders(Wilcox, Kean, Ritchie, Smith, & Wilcox, 1994). The proposed strategy combines the two strategies creating relationships between four elements by using the levels of participation as the link between the two matrixes. The levels of participation, the communication tool, the stakeholders participating, and the stages of the process became the parameters of the new approach proposed.

Wilcox studied the ladder of levels of participation and then added two other dimensions to the ladder. The phase or stage of participation and the fact that stakeholders may be at different levels or stages of participation(Wilcox et al., 1994). He proposed a set of questions that should help decide the approach:

Who are you? For example someone in a position of power controlling funds or other resources. Someone with influence because you are planning or managing a participation process. Someone with professional expertise or knowledge?

Figure 1: the proposal of Hudson, and Wilcox parameters. source, author.

What do you want to achieve by working in a participatory style? To try and develop plans that meet people's expectations. To give people a say in the plans. To give people control over the solutions. Who will have the final say over decisions? Yourself. A management team. Everyone who gets involved. A political institution or other body.

How ready are people, and organizations, to work in a partiipatory way? Do they have the desire? Do they have the skills? Do they have the authority?

On the other hand, Hudson's matrix is based on the concept of interactive participation. He believes that the key to successful participation is using the proper communication tool. He even gives big attention to new technological participation tools. He proposes a matrix that connects the participation tools with the levels of participation. His main goal is to transform participation from passive to interactive(Hudson-smith et al., 2002).

The framework fosters the concept of both Hudson, and Wilcox by combining them to create the relationship between the parameters. Different levels of participation are appropriate for different situations, at the same time there isn't one 'community' but many interests – or stakeholders – to consider. The process itself takes time could be months or even years, so the precision of who should be involved and when need to be as accurate as possible. To achieve the best results the participants must be informed clearly about the part they do in the process, in what stage of the planning process and how is the level of their participation and how to participate exactly.

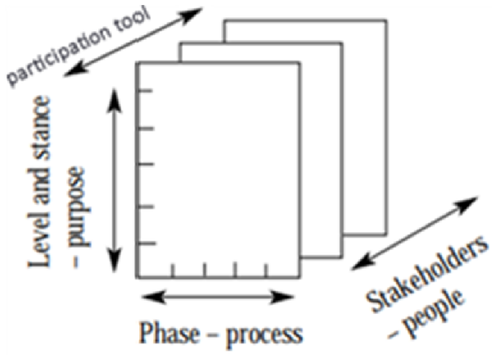

Figure 2: four-dimensional participation framework. Source, information based on Wilcox, 1994.

3.2 Parameters of the framework

3.2.1 Levels of public participation

The concept of involving the public in the development process is not new, a wide range of development agencies experimented with the people involvement technique. Many companies implement this technique to collect data, interactive analysis, develop power, and improve decision making. To achieve this goal, several researchers proposed their sets of participation levels. The typology used in this approach was proposed by Jules N. Petty in 1992. He divides the participation levels into seven different levels based on the extent of power given to the participants(Pretty, 1994). The typology seemed very convenient to the study as the participants (stakeholders) were the key elements that link all the other cornerstones to one another.

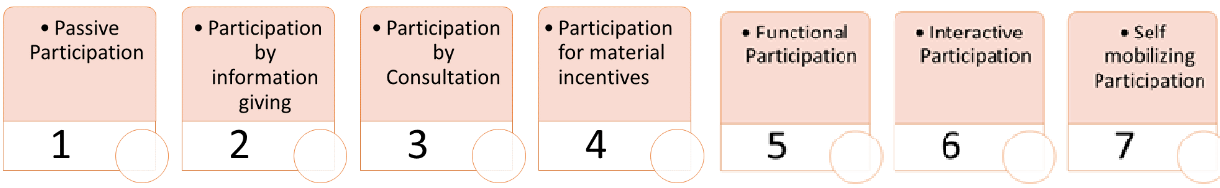

Figure 3: the levels of public participation according to Pitty.

3.2.2 The Stakeholders' Involvement concerning the Levels of Participation.

The urban crisis center created a table for all possible stakeholders appropriate for every different context. The center also highlights that there is always a large number of stakeholders involved but that doesn't mean that it is needed to coordinate with all of them all of the time. The first category and the most important stage is The Affected Population. The affected population comprises many categories under its umbrella, they can consist of citizens of several cultural, social, ethnic, and economic backgrounds, and they can also be direct or indirect affected population. The urban crisis center recommends the participation of the affected population in all the stages of participation. The second category of stakeholders in the international actors and donors, such as UN bodies, international humanitarian organizations. The job of these commits varies

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

between the first four participation moods. National governments are also one of the important categories of participating stakeholders, they can be in form of planning offices, disaster management bodies, or specific ministries or departments. The next category is the local governments, which are the municipals, city councils, government institutions, their area of participation is mainly in the executive participation area. They're followed by the urban planning institutions, which could be specific government planning offices, their job in the planning and execution, and monitoring stages. The private sector is one of the acting stakeholders participating in the process, which could be any financial institution), large national businesses, and small local vendors.The private sector plays a big job in executing the projects, and planning stages. The next category is the community leader, this category is considered one of the most important categories of the stakeholders due to their ability to influence public opinions. The final category is civil society, local NGOs, community-based organizations, and non-state actors.

There is an ideal pattern for the participation of the stakeholders. This pattern was proposed by Zlatka Ljubimir, and the linkage between the levels of participation and the stakeholders was designed by Wilcox. However, this pattern does not happen in real-life participation projects because, as mentioned before, the city system controls the stakeholder's pattern of participation.

4 PUBLIC PARTICIPATION IN EGYPT

The Arab Republic of Egypt is a transcontinental nation in the northeast of Africa and southwest corner of Asia via the Sinai Peninsula. According to the latest constitution declared in 2014, The republic is a unitary country with a decentralized public participation pattern.

The Egyptian administration is designed on a vertical structure. Under Law 43 of 1979, local administration is divided into 3 subnational levels. At each level, there is a governing structure combining representative councils and government-appointed executive bodies headed by governors, district officers, and mayors, respectively. Governors are appointed by the president, and they, in turn, appoint subordinate executive officers. The backbone of the state apparatus runs downward from the Ministry of Interior through the governors' executive(Constitution of the arabe republic of egypt, 2012).

In 2012, The Shoura Council agreed on several key principles to guide reforms in local governance, including the devolution of authority from the central level to the local level, and the decentralization of taxation and budgetary authorities.

4.1 Effective public participation framework

The latest Egyptian Constitution (2014) states that "Citizen Participation in public life is a national duty," but limits participation as "the right to vote, run for elections, and express opinions in referendums, according to the provisions of the law."(Constitution of the arabe republic of egypt, 2014) This limited view of citizen participation is debatable since electoral politics and referendums launched by the executive branch will not be enough to absorb the pent-up and ongoing demands of the public for significant quality of life changes and greater government responsiveness, accountability, and transparency(Constitution of the arabe republic of egypt, 2014).

4.2 Central level

At national level the Parliament adopts laws setting out the allocations of local authorities and carries out a tight form of legislative, executive and taxation/budgetary oversight(Constitution of the arabe republic of egypt, 2013, 2014).

Parliamentary oversight:

The People's Assembly holds overriding powers over the local councils:

- Members of the People's Assembly have the right to audit popular council meetings, participate in debates, and ask questions, offer suggestions and request information.
- The Minister in charge of local administration is required to present an annual report to the President of the People's Assembly on the activities and accomplishments of the local popular councils.
- The Assembly can take the form of a commission in charge of evaluating the activities and accomplishments of each local unit.

4.3 Executive oversight

Central authorities have the responsibility and power to create and disband local authorities. Irrespective of the established principle of electing local council, de facto "the possibility of nominating particular members – by central authorities – has not been excluded".

The Governors are appointed by the President of the Republic. The nomination of mayors and heads of urban subdivisions, as well as changes and transfers within or between local authorities, are carried out upon decision of the Prime Minister, with the agreement of the Governors in question.

4.4 Regional level

Law 475 of 1977 also divided the Republic into 7 economic regions without any administrative/political function. At regional level, within the governorates, the governors and the governorate local council have extensive powers over lower local councils especially at legislative and budgetary levels. In particular, they can approve or oppose decisions made by lower popular councils. Furthermore, governorate local popular councils have the power to stand in for local popular councils under the control of the governorate for projects that councils are unable to carry out themselves. As for financial issues, the Governor's approval is required for any taxes that a local town council plans to raise. They also have the power to oppose decisions made by local popular councils.

4.5 Local level

District local popular councils exercise oversight over the activities of local town and village councils within the district and can approve their decisions.They also have control over various local services covering more than one local unit within the district's framework.

Town popular councils: exercise powers of oversight over urban subdivision councils and guarantee coordination of their activities. They also control local services within the framework of the town or city's constituency. Urban subdivision popular councils have responsibilities and powers similar to those of town popular councils. The following tables propose a public participation pattern (based on the governance system of cities in Egypt previously mentioned) to ensure the effectiveness of the process, however, this paper will test the first table only.

Table 2: effective public participation framework.

4.6 The re-development project of Elkhaledin Garden

The khaledin Garden is located in front of the Mosque of the Leader Ibrahim, and is slightly higher than the surface of the ground, including a garage with its area below, and the garden includes a group of statues of influential Egyptian figures, such as Sayed Darwish, pioneer of Arab music, Abdullah Al-Nadim, the preacher of the Arab revolution, Hassan Iskandarani, nicknamed Amir The seas, and some other national symbols, whose names are engraved on marble pieces, have been extracted from the garden.

Figure 4: Ariel photo of the garden. Source, (Yom sabe3, 2021)

The garden began to deteriorate and the loss of its grass-planted ground, beginning with the January 2011 protests, as thousands flocked to it, despite the danger it poses to them with the increasing numbers, to erode its columns without any of them or those in charge of care.

Negligence struck the Immortals Park, which is part of the square of the Leader Ibrahim Mosque in central Alexandria, where it became a neglected garden for more than 10 years, despite its location in the middle of the Alexandria Corniche, and a garage under the garden turned into a den for outlaws, criminals and drug users at night.

Users and citizens began complaining about the situation of the garden, and years after, the government responded and the development project took place. The participation of the public need to be present in all of the development stages. However, this paper investigates the participation of the public in the first stage only.

5 DATA COLLECTION METHODOLOGY

Due to the complex and diverse themes of the research, data for this research were collected using both qualitative and quantitative methods. Field observations, case study analysis, interviews and mixed questionnaires survey were used to collect the relative data.

Interviews with local residents, users and passing by personals took place while investigating the area.

The following questions were asked;

- Did you complained about the situation of this garden before(Complaint official filing/ social media)
- Were you informed/invited to any session hosted by your governor/ district depute introducing any project in your city?
- Did you propose any ideas to renovate or use the garden before?

An 8 minutes questionnaire was also published on all social media platforms to investigates the participation of the public . The form of the question may be either closed ended format or open ended format. Therefore, due to research's nature and intended goals, structured questionnaire was designed with mixed questions. The questionnaire into five main sections; this first section is dedicated mainly to know more details about the participant's lifestyle and background. The second section investigates the participant's relationship with the city system and the local governance system. The third section discuss the participation of the users in the planning stages of the process. The fourth evaluates the participant's experience in the project. The fifth and final stage investigate the respondent's perception of public participation.

The target respondents are people from the eight mentioned categories in the questionnaire. For this questionnaire to success, users form all of the eight categories need to participate and take this questionnaire. The eight categories are (urban planning institutes, affected population, national government, local government, participation moderator, academic researcher, civil society, private sector).

5.1 The renovation project

Last year(2020), the people of Mahatet El Raml, woke up a day on heavy voices of demolishment. The responsibles responded to the needs of the citizens. The development work was being carried out at the

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

highest level, and it contains the reopening of the garage to include two floors to accommodate 300 cars and a chain of stores, in addition to developing the upper yard, preserving statues, developing lighting systems, as well as adding many services to citizens and setting up a maintenance system to continue with us after.

The roof opposite the garage was a garden and then began to collapse from neglect, and the courtyard was replaced by a theater with cafeterias, and this was done two years ago, and the truth is that the people suffered from the control of thugs and street vendors, and with the darkness of the streets we see soil ready to receive drug users and a hotbed Street children who are exploiting the garden, besides the neglect that imposed control on the garden, but the governorate sought to develop it away from the control of these people, to open the mall and rent cafeterias towards the sea. As for the part of the garden and the seating of passers-by, some stairs resemble the Roman Theater as seating terraces, and I don't think it will be closed in the face of overpowering.

Figure 5: The location of Elkhaledin garden after development project.

As previously mentioned, the feedback was collected using two methods, the one to one interviews, and the survey feedbacks. The interviews were conducted with users, administration, and shop keepers of the aria.

5.2 Interviews feedbacks

The head of a central district indicated that the garage, in its current state, is not suitable for use, due to the weakness of the facilities because it is ramshackle, and a committee has been formed to study the construction situation of the garage and the committee's report recommended restoring the garage, which will cost the governorate more than demolishing and rebuilding it, what the current governor, Muhammad Abd, called Al-Zahir calls for a halt to restoration work and a comprehensive plan for the area as a whole.

Citizens, users, and even visitors to the place started raising complaints. "Unfortunately, it became a shelter for thugs and so-called revolutionaries until W.H.O. became deserted and permissible for thieves, pimps and girls of the night. Alas, I have lived near the mosque since 1958" (said a citizen living in the area)

"This garden and this project is a complete failure, even though its place is beautiful and promising, and unfortunately the place is not exploited at all "(an affected).

One of the interviews held was with an architech from the design team of the project who states that the design process did not take much time because they did not have any feedbacks from the public, and that they only inticipated their design vision.

Survey feedbacks:

500 citizens were asked 30 questions divided into 5 main categories: the first one for general informations, the second category mapes the relationship between citizens and government, the third section investigates the public participation of users in the development project, the fourth part allows the citizens to evaluate the project, and the fifth and final one investigates the citizen perception of good governance. However, this paper will discuss the participation of public in the development project of the garden. The following tables presents statistical results of the participants responses. The survey was shared on surveymonkey platform, and it is avaible in the following link: https://www.surveymonkey.com/r/CJPFV8S

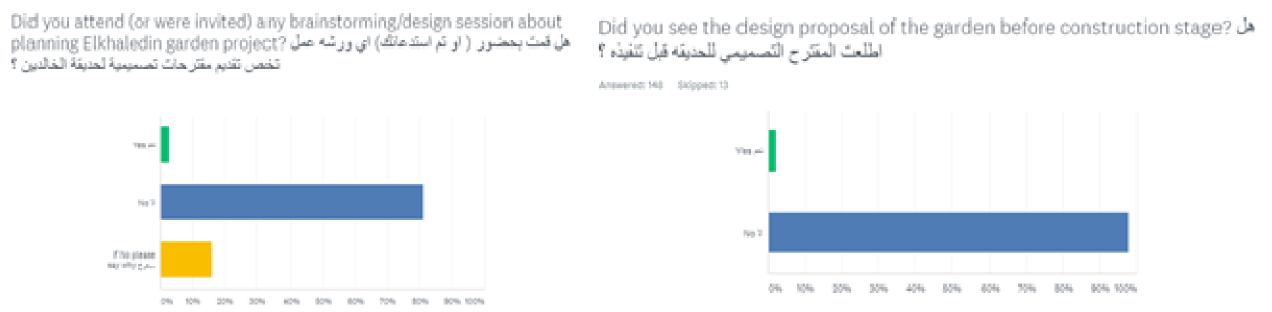

Figure 6: statistical review to the results of the survey's responds (part 1).

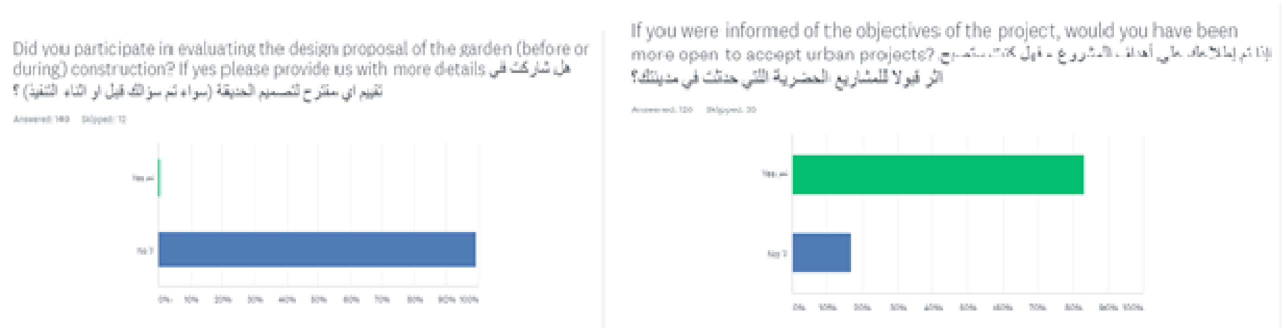

Figure 7: statistical review to the results of the survey's responds (part 2).

Figure 8: statistical review to the results of the survey's responds (part 3).

6 RESULTS

The results of the re-development project were divided between encouraging the new design and transformation and hating the outcome, the average rating of the project was 4.1 star (figure 8). Some citizens said " The garden was destroyed and turned into cafeterias, and the people of Alexandria would not have an outlet because the cafes on the sea corniche occupied the public walkway and took the sidewalks for their benefit without supervision until it became a knot for the Alexandrian citizen. Painting the seats so that the majority do not sit in them and have to enter the exaggerated cafeterias." While others were very happy with the results and enjoying how safe and clean the location became. Another citizen in Alexandria noted "The superiors will not let the people enjoy the development in the absence of oversight. It will not be in the interest of the simple citizen and not only in tourism development, as it does not increase his dissatisfaction, especially as the world is moving towards increasing green space." One of the residents, said that successive cafes are being built and the features of the park are being blurred, and the statues have disappeared in the middle of the cafeteria buildings. There is a garden that the largest part was completely covered with "tiles", but restoring the heritage form is more important than creating an income or financial return for the governorate.

Participants of the survey were asked if they agree with the development project or they would prefer other project in the exact same location. Results were fascinating; only 32.47% of the total number of participants were satisfied with the outcome that came out of the development project (transforming the garden into a food court) while 67.33% did not like the project and did not agree with the importance of creating a new food court in the city. 46.11% of the participants proposed alturnitve projects that in their

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

opinion they need more than the food court. 70% of the participants agreed on renovating the garden while living it as it is (a public garden), others proposed projects like open auditoruim, cultural center, towers, and museums. Knowing that 77.75% of the total number of the survey‘s participants answered this question.

The participants were also asked if they have the chance to participate will they be opened to participate or not, 76.97% of the total number of particiants will participate, 21.71% will still stick to not participating. Some participants even commented “ yes, because it took my needs and aspiration into consideration, and now I feel as a part of this”. Knowing that 78% of the total number of the survey’sparticipants answered this question.

Participants were also asked if they would be more acceptable of the urban projects fostered by the governemnets if they were aware of the results. The results show that knowing the goals of the project has increased the rate of acceptance to 83.13% to 16.58 % who will not accept the projects even if they know the goals. However, 2.02% of the respondents noted that they will not link their acceptance with knowing the goals, but the quality of the goal and how helpful it is to the citizens. Knowing that only 60% of the total number of the survey’sparticipants answered this question.

When comparing the framework proposed with the participation pattern that actually happened in the situation (the green slots present the actuall participation pattern while the orange slots present the framework proposed), we can see that the not all the stakeholders where involved in the process. Academia where just used as information givers. The affected population where also information givers, they only provided the authorities with complaints explaining the situation. The nation government was consultant to the process while the local government was controlling the process. The rest of the stakeholders were not participants in this process.

The results of both; the interviews, and the survey concludes that the system is on th e right trac but it is on the first step to a sucessful effective public participation. The empowerment that was given to the locl government over the central government in this projects indicated a promessing decentrized government. Presenting an area for the Academic field is a new approach, even though their participation was not at the expected level. Responding to the complains of the affected population is also considered a type of participation. The urbn planning institute is usualy a part of any development project in the city but in this situation they were not part of this process. The private sector only participated as contractors and cafees owner but they were not part of the planning process. Community leaders, NGOs, civil socity, and international actors and donurs were not a part of this project even though they were recommended by the framework.

Table 3: comparison between what the framework proposal and the actual participation pattern.

7 FURTHER RESEARCH

Completing the investigation process requires more interviews with the current users, questionnaires to gether more detailed information about the participation process of this project. The investigation also needs to compare the participation process in the four stages of planning not only the first stage. The study also needs investiagting similar participaion of citzens in urban projects in unitary decentralized countries.

8 CONCLUSION

The paper presents an effective public participation framework for the stakeholders to participate in the decisions concerning their own cities. It proposes change conjointly with the governance system. The unitary system imposes different participation pattern than the federal system. This proposal connects the public participation levels with the stakeholders, the communication tool, and the urban development stages. The factors produce four tables, each table presents a development stage (assessment, design, monitoring , and evaluation). Each table proposes a relationship between the levels of participation, stakeholders participating and propose an effective public participation tool.

When applying the framework on the case of Alexandria, Egypt, the framework was compared with the actual situation that is happening now. This paper only compared the first table of the framework (the data collection stage) with what happened in the data collection stage in Elkhaledin garden case. The results indicates promising development process in Egypt's system. However, further research will provide more details about the process of public participation in the cities of Egypt and how to modify the current situation to ensure more effective public participation practice.

Gründerzeitliche Innenhöfe als Ressource zur Verbesserung des Mikroklimas

Petra Kubin, Aglaee Degros

(DI BSc. BA Petra Kubin, Institut für Städtebau TU Graz, petra@kubinquadrat.at)
(Arch. Univ.-Prof. Aglaee Degros, Institut für Städtebau TU Graz, a.degros@tugraz.at)

1 ABSTRACT

Einige Bezirke von Graz weisen eine für die Gründerzeit typische Blockrandbebauung auf. Innerhalb dieser Blöcke sind große Freiflächen mit nur wenig Verbauung erhalten geblieben. Da Grünflächen einen großen Teil dieser Innenhöfe einnehmen, sind sie das Objekt dieser Forschung, in der herausgearbeitet werden soll, welche klimatisch beeinflussenden Merkmale für gründerzeitliche Grazer Innenhöfe charakteristisch sind.

Die Entstehung der Innenhöfe wird beleuchtet und festgestellt, durch welche Umstände es zu diesen durchschnittlich 0,62 Hektar großen Freiflächen kommen konnte. Das Untersuchungsgebiet bezieht sich auf die Innenhöfe der sechs Bezirke von Graz, die einen besonders großen Anteil an gründerzeitlicher Bebauung haben. Durch eine Fotodokumentation wurden 131 Innenhöfe von Graz aufgenommen. Alle der ausgewählten Innenhöfe weisen folgende Merkmale auf: Sie befinden sich in einem der Grazer Bezirke, der zum großen Teilen gründerzeitliche Bebauung aufweist, sie sind von gründerzeitlicher Bebauung umschlossen, sie werden vor allem der Funktion Wohnen zugeordnet oder sind zum Großteil von Wohnungen umschlossen, die Innenhöfe sind ganz oder zum Großteil geschlossen.

Bestimmte, dem Mikroklima zuordenbare, Häufigkeiten wurden anhand dieser Fotodokumentation mittels deskriptiver Analyse ausgewertet. Die Blöcke und Innenhöfe sowie ihre Bebauungen wurden über GoogleMyMaps vermessen. Als Ergebnisse lassen sich bestimmte Merkmale wie Bebauung, Grad der Versiegelung sowie Vegetation innerhalb der Innenhöfe in den jeweiligen Bezirken erkennen.

Diese großen privaten Freiflächen stellen eine wichtige Ressource für ein angenehmes Mikroklima im städtischen Wohnbereich dar. In Zukunft wird die Erhaltung sowie die Verbesserung dieses Naturraumes eine wichtige Aufgabe darstellen, da es zu immer mehr Wärmeinseln im urbanen Bereich kommen wird. Durch ein verstärktes Bewusstsein für die Relevanz der begrünten Innenhöfe im Stadtbereich könnten mehr Anreize für klimarelevante Projekte entwickelt werden.

Keywords: Gründerzeit, Mikroklima, Graz, Innenhof, Blockrandbebauung

Abbildung 1: Vergleich Satellitenbild Graz und Wien (Google Maps 2021)

2 EINLEITUNG

Graz ist die zweitgrößte Stadt Österreichs mit einer Größe von 127,58 Quadratkilometer und rund 300.000 Einwohnerinnen und Einwohner.[1] Die strukturierte Blockrandbebauung der Gründerzeit hat die Stadt mit vielen, meist größeren Städten, gemeinsam. Innerhalb der Blockrandbebauung sind halb öffentliche Freiräume zu finden. Verglichen mit anderen Städten findet man in Graz größtenteils wenig Verbauung in diesen Bereichen. Die Bebauungsdichten wurde in der Dissertation „Gründerzeitstadt 2.1“ mittels Referenzquartieren von Wien - Rudolfstadt und Graz - Herz-Jesu-Viertel miteinander verglichen, da sie als typische Bebauung von Gründerzeitvieteln angesehen werden. Das Quartier in Wien weißt eine

[1] Stadt Graz, Zahlen + Fakten: Bevölkerung, Bezirke, Wirtschaft, Geografie.

Quartiersdichte von 2,54 auf, das Quartier in Graz hingegen 1,31. Zur Veranschaulichung wurden beide Quartiere abgebildet[2] (siehe Abbildung 1).

2.1 Entstehung der gründerzeitlichen Innenhöfe

Die Entstehung der Blockrandbebauung mit ihren Innenhöfen ist der industriellen Revolution geschuldet. Durch die Industrialisierung und die damit in Verbindung stehende Landflucht kam es in vielen Städten Europas in den Jahren von 1850 bis 1900 zu einem starken Anstieg der Bevölkerung. Großstädte wie Wien und Berlin sind in kürzester Zeit so stark gewachsen, dass sich die Bevölkerungsanzahl in nur 50 Jahren mehr als verdreifacht hat (siehe Abbildung 2). [3] [4] [5]

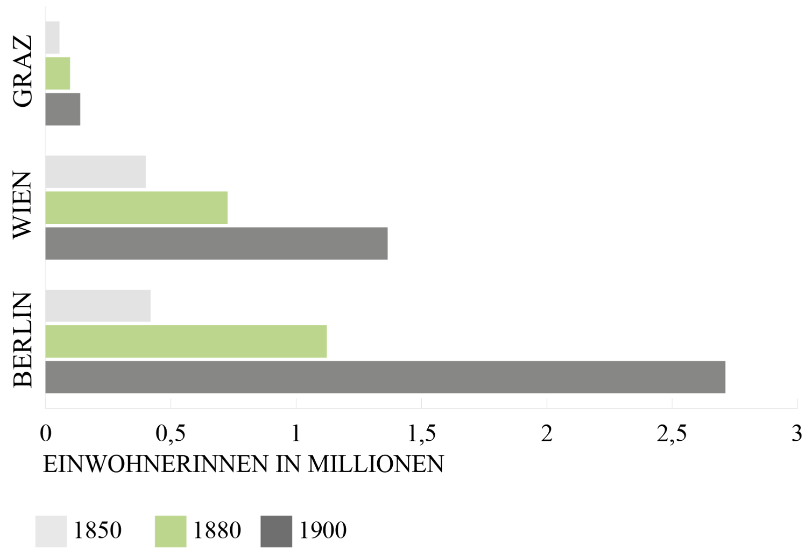

Abbildung 2: Anstieg der Einwohnerinnen- und Einwohnerzahlen in der Gründerzeit

Um in dieser kurzen Zeit möglichst viel Wohnraum zu schaffen, wurde das Rastersystem aufgegriffen und Wohnblöcke entstanden. Durch fehlende Planungs- und Bodenrechte gab es keine Enteignungen für den Straßenbau. Meist wurden in großen Städten große Blöcke gebaut, um möglichst wenig Bauland an den Straßenbau abgeben zu müssen. Jedoch war das Bauland so wertvoll, dass die inneren Bereiche des Blocks mit Wohnungen verbaut wurden. Diese Bebauung entstand vorwiegend nicht nach einer gewissen Zeit, sondern wurde gleich in der Entstehungsphase mitgeplant. Ein großer Teil der noch freien inneren Bereiche der Blöcke wurden mit Wohnungen verbaut. Oft wurde der noch freie innere Bereich der Blöcke als Erschließungsbereich genutzt. Nur wenige Bereiche blieben als Grünflächen frei vom Wegesystem.[6] [7] [8]

Auch kleinere Städte wie Graz wuchsen in der Gründerzeit, gemessen an ihrer Ursprungsgröße, stark an. Jedoch musste, aufgrund der geringen Bevölkerungszahl, nicht annähernd soviel Wohnraum auf engstem Raum geschaffen werden, wie in größeren Städten. Ein planvolleres Handeln war möglich. So wurde zwar auch Graz im Rastersystem erweitert, jedoch war die Notwendigkeit, die inneren Bereiche der Blöcke zu bebauen, nicht gegeben. Die Bodenpreise waren somit auch nicht so stark gestiegen wie jene in größeren Städten und die Blöcke wurden kleiner gehalten. Weiters kam Graz zugute, dass das Baugeschehen meist von den dort lebenden Bürgerinnen und Bürgern bestimmt wurde und nicht von Grundstücks- und Gebäudespekulantinnen sowie Grundstücks- und Gebäudespekulanten. Somit wurde mehr auf qualitätsvolles Wohnen geachtet als auf den Profit.[9]

Die Größe der Blöcke der gründerzeitlichen Blockrandbebauung ist eng mit dem Straßenraster verwoben. Die freibleibenden Flächen innerhalb des Blocks wurden, je nachdem wie teuer das Bauland war, so eng als möglich bebaut. Große freibleibende Grünflächen waren in den meisten Städten eher eine Ausnahme. In Graz hingegen waren diese die Regel.[10] Als Gründe für die großen Grünflächen innerhalb der gründerzeitlichen Bebauung in Graz können zwei ausschlaggebende Faktoren genannt werden:

- planvolles Bauen aufgrund der geringeren Bevölkerungsdichte und somit geringerem Bedarf an Quartieren
- günstigere Bodenpreise, kleinere Blockgrößen

Diese Innenhöfe bilden heute oft grüne Freiräume mit einem eigenen Mikroklima.

2.2 Klima in Graz

Durch die Stadtklimaanaylse, welche die Stadt Graz in Auftrag gegeben hat und vom Institut für Geographie und Raumforschung an der Karl-Franzens-Universität Graz durchgeführt wurde, wurden relevante Klimadaten der Stadt Graz aufgezeigt und grafisch dargestellt. So entstand die Stadtklimakarte von Graz. In Abbildung 3 ist ersichtlich, dass vor allem der Innenstadtbereich und die Bereiche mit gründerzeitlichen Blockrandbebauungen stark von Überwärmung betroffen sind (dunkelrote Bereiche zeigen eine sehr starke Überwärmung, hellrote Bereiche zeigen eine starke Überwärmung). Gründe hierfür sind die dichte Bebauung und die geringe Luftzirkulation. Weil Graz aufgrund seiner Tallage recht windarm ist, ist die Durchlüftung stark eingeschränkt. Die Bildung von Wärmeinseln ist die Folge.[11]

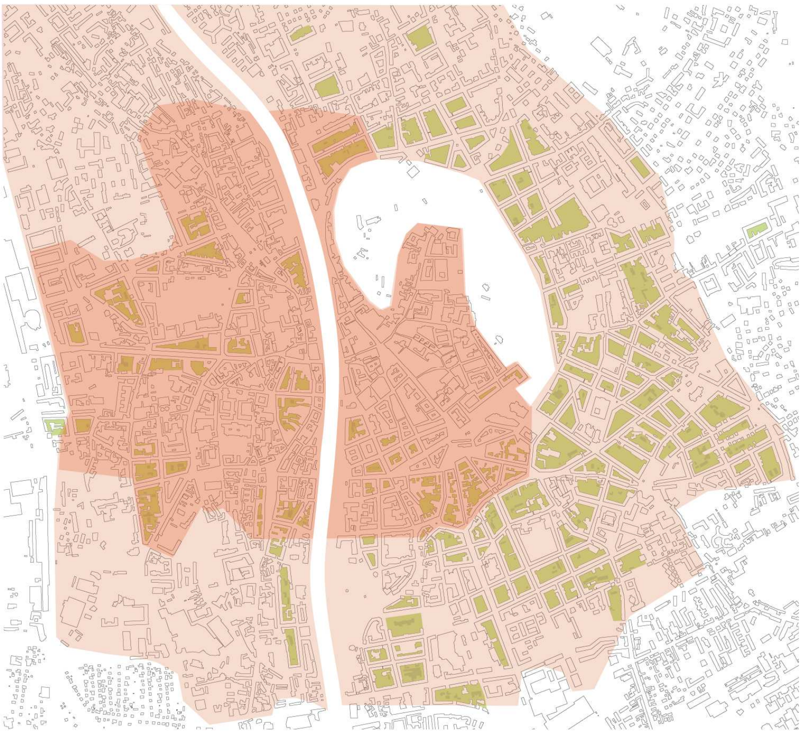

Abbildung 3: Wärmebereiche der Stadt Graz nach Daten der Stadtklimaanalyse

In der Beschreibung der Stadtklimaanalyse wird darauf hingewiesen, dass Bereiche der Stadt Graz mit überwiegend begrünten Innenhöfe im Bereich des Gründergürtels ein bioklimatisch behaglicheres Wohnklima aufweisen, obwohl sie sich innerhalb der Wärmeinseln befinden.[12]

Ausschlaggeben für ein besseres Wohnklima sind die Strömungsverhältnisse innerhalb der Innenhöfe, welche im direkten Zusammenhang mit dem Gebäudeabstand stehen. Beim Innenhof des Typs Lichthof ist der Gebäudeabstand sehr gering. In Graz ist diese Bebauungsform im Stadtkern zu finden. Hier kommt es zu einer relativ geringen Durchlüftung, da der Großteil der Strömung über die Häuser geführt wird. Im gründerzeitlichen Innenhof ist das Verhältnis Hofabstand zu Gebäudehöhe größer und somit vorteilhafter.

[10] Vergleiche Luftbilder Google Maps, Wastlerplan
[11] Lazar/Sulzer, S. 169.
[12] Lazar/Sulzer, S. 224-225.

Hier herrschen gute Lichtbedingungen und es kommt zur Ausbildung kleinräumiger Zirkulationen. Baumbestände verlangsamen zwar die Zirkulation, jedoch sorgen sie auch für Beschattung und verringern die Maximaltemperaturen. In Abbildung 4 wird dies dargestellt. Die blauen Pfeile stellen die kalte Luft, die roten Pfeile die heiße Luft und die orangen Pfeile warme Luft dar. Die schwarzen Pfeile veranschaulichen Zirkulationen, die je nach Außentemperatur unterschiedliche Erwärmungen aufweisen können. Durch begrünte Innenhöfe wird die Luftfeuchtigkeit erhöht, was dem Wohnklima im trockenen Stadtklima zugute kommt. Besonders vorteilhaft ist es, wenn die Häuserreihen Baulücken aufweisen. Eine Bebauung der Innenhöfe wirkt sich wiederrum negativ auf die Ventilation aus. Dadurch bleiben im Winter auch Emissionen bei nur langsamer Verdünnung in den Innenhöfen. Im Sommer kommt es, wenn wenig Durchlüftung gegeben ist, vor allem bei stark versiegelten Innenhöfen zu starken Aufhitzungen. Laubabwerfende Bäume verbessern die bioklimatische Bedingungen hier besonders und dienen auch noch als Staubfilter.[13] [14]

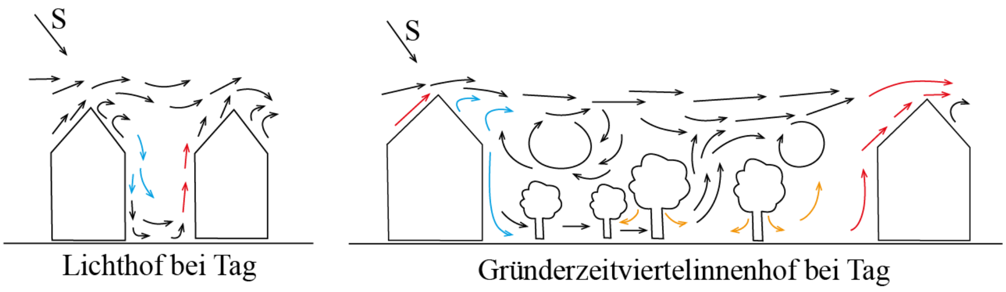

Abbildung 4: Vergleich Zirkulation Lichthof und Gründerzeitviertelinnenhof[15]

2.3 Forschungsfrage

Aus der Stadtklimaanalyse ergibt sich, dass Innenhöfe wertvoll für das Mikroklima sind, wenn sie nicht bebaut sind und Bäume beziehungsweise entsprechende Grünflächen beinhalten. Dies ist der Grund, warum in dieser Arbeit die Versiegelung und Vegetation der Innenhöfe im Fokus steht.

Dazu wurden verschiedene Parameter, wie die Anzahl der Bäume oder versiegelte Flächen in einzelnen Innenhöfen, mittels deskriptiver Analyse ausgewertet.

Die Forschungsfragen lautet: Wie können gründerzeitliche Innenhofe zu einer Verbesserung des Stadtklimas beitragen?

3 METHODE

3.1 Untersuchungsgebiet

Das Untersuchungsgebiet der gründerzeitlichen Innenhöfe bezieht sich auf Graz. Der Grazer Stadtraum wurde auf sechs Bezirke eingegrenzt, da in diesen heute noch ein großer Teil der Bauten der gründerzeitlichen Stadterweiterung von Graz erhalten ist. Es handelt sich um die Bezirke Innere Stadt, St. Leonhard, Geidorf, Lend, Gries und Jakomini, welche sich außerhalb des Altstadtkerns entwickelt haben. Diese halböffentlichen Bereiche werden in Graz als Innenhöfe bezeichnet. Im Zuge dieser Forschungsarbeit ist der gründerzeitliche Grazer Innenhof wie folgt definiert:

- Der Innenhof befindet sich in einem der Grazer Bezirke, der zu großen Teilen gründerzeitliche Bebauung aufweist.
- Der Innenhof ist von gründerzeitlicher Bebauung umschlossen.
- Der Innenhof wird vor allem der Funktion Wohnen zugeschrieben oder ist zum Großteil von Wohnungen umgeben.

[13] Lazar/Sulzer, S. 236-239.
[14] Laue, S. 46-47.
[15] Lazar/Sulzer, S. 226.

- Der Innenhof ist ganz oder zum Großteil geschlossen.

Von anfangs 246 Innenhöfen erfüllten 131 die oben bereits angeführten Kriterien und wurden für diese Arbeit in die Liste der gründerzeitlichen Grazer Innenhöfe aufgenommen. Bei alle denen sind klare gründerzeitliche Strukturen abzulesen. Dies wurde zuerst durch die Analyse von Luftbildern und Katastern festgelegt und in Tabellen eingetragen. Durch eine Begehung wurde die Annahme überprüft. Um eine bessere Vergleichbarkeit gewährleisten zu können, wurden Innenhöfe ausgewählt, bei denen die umliegende Bebauung größtenteils dem Nutzen „Wohnen" entspricht. Dies wurde im Zuge der Begehung festgestellt. Indizien für „Nicht-Wohnen" waren Beschriftungen an Haustüren, die auf eine gewerbliche Nutzung hinwiesen, wie Firmenlogos, Arztpraxisschilder, Schriftzüge von Dienstleistungsanbieterinnen und Dienstleistungsanbietern, Beschriftung als Universitätsgebäude oder Schule. Die Abbildung 5 zeigt die ausgewählten Innenhöfe grün eingezeichnet.

Abbildung 5: Mapping ausgewählter Innenhöfe

3.2 Messungen GoogleMyMaps

Um Daten über die Blockgröße, Innenhofgröße und Bebauung des Innenhofes zu bekommen, wurden Satellitenbilder, die über GoogleMyMaps frei zugänglich sind, vermessen.

3.3 Fotodokumentation

Bei der Fotodokumentation wurden zuerst alle in Frage kommenden Innenhöfe auf einem Schwarzplan erfasst und nummeriert. Dann fanden Begehungen statt, um alle 131 Innenhöfe bildlich zu erfassen. Hierfür wurden die Innenhöfe von mindestens drei unterschiedlichen Blockseiten mehrmals fotografiert. Diese rund 4.000 Fotografien wurden in Anbetracht der drei Kategorien Eigentumsverhältnisse, Nutzung, und Mikroklima untersucht und statistisch bewertet. Bei der Kategorie Eigentumsverhältnisse konnten keine

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Faktoren festgestellt werden, welche sich direkt auf das Mikroklima auswirken könnten. Deshalb wird auf diese Kategorie in diesem Paper nicht näher eingegangen. Bei der Kategorie Nutzung wurde der Aspekt „Geschätzte aktive Nutzung des Innenhofes durch die Bewohnerinnen und Bewohner“ auf die Bezirke hin ausgewertet und beschrieben. Die Kategorie Mikroklima wurde in die Parameter Bodenbelag und Vegetation unterteilt. Bei dem Bodenbelag wurde zwischen Asphalt, Beton, Pflastersteinen, Kies, Erde und Wiese unterschieden. Bei der Vegetation wurden Bäume und Sträucher aufgenommen. Mittels deskriptiver Analyse wurden alle Innenhöfe bewertet. Da nicht alle Innenhöfe zu 100 Prozent begangen werden konnten, wurden die Ergebnisse danach gewichtet, wie viel vom Innenhof bewertet wurde. Eine Skala der Häufigkeit wurde erstellt und von eins (nicht vorhanden) bis vier (oft /viele vorhanden) bewertet. Diese Bewertung erfolgte je nach Größe des Innenhofs, da eine nummerische Bewertung verfälschte Ergebnisse je nach Größe des Innenhofes ergeben hätte. Als Beispiel kann hier die Kategorie Bäume angeführt werden in dem „1“ kein Baum vorhanden und „4“ viele Bäume vorhanden beschreibt. In Prozenten wird dargestellt, wie häufig die angegebene Skalenbewertung vorkommt (Tabelle 1). Diese Häufigkeiten wurde für jeden Innenhof, für jeden Bezirk und gesamt erstellt. Weiters wurden Mittelwerte und Standartabweichungen berechnet. Die statistischen Analysen wurden mit dem Programm Excel Version 14.0.0 durchgeführt.

Vegetation Baum						
Skala	Innere Stadt	St. Leonhard	Geidorf	Lend	Gries	Jakomini
1	11%	0%	0%	0%	3%	0%
2	15%	3%	0%	17%	0%	4%
3	74%	61%	44%	62%	89%	72%
4	0%	36%	56%	21%	8%	24%

Tabelle 1: Häufigkeit Vegetation Baum

4 ERGEBNISSE: MERKMALE DER INNENHÖFE HEUTE

In der Tabelle 2 wird die Anzahl der ausgewählten Innenhöfe je nach Bezirk veranschaulicht. Die Anzahl wird in absoluten Zahlen und in Prozentwerten von allen ausgewählten Innenhöfen angegeben.

Ausgewählte Innenhöfe nach Bezirken						
Bezirk	Innere Stadt	St. Leonhard	Geidorf	Lend	Gries	Jakomini
Anzahl der untersuchten Innenhöfe (%)	16 (12%)	37 (28%)	25 (19%)	10 (8%)	15 (11%)	28 (21%)

Tabelle 2: Anzahl der ausgewählten Innenhöfe

Die ausgewählten gründerzeitlichen Innenhöfe machen eine Gesamtfläche von 79,49 Hektar (ha) aus. Die größten gründerzeitlichen Blöcke mit Innenhöfen befinden sich im Bezirk Lend mit durchschnittlich 1,41 ha Blockgröße und 0,81 ha Innenhofgröße. Im Mittelwert sind die ausgewählten Innenhöfe 0,62 ha groß. Die kleinsten Blöcke sowie auch Innenhöfe sind im Bezirk Innere Stadt mit einem Mittelwert von 0,85 ha und beziehungsweise 0,36 ha zu finden. Die gesamten Innenhofflächen nach Bezirken sind in Tabelle 3 dargestellt.

Fläche der ausgewählten Innenhöfe gesamt nach Bezirken						
Bezirk	Innere Stadt	St. Leonhard	Geidorf	Lend	Gries	Jakomini
Fläche in Hektar	5,82	22,84	16,30	8,05	11,23	15,24

Tabelle 3: Innenhofflächen nach Bezirken

4.1.1 Bebauung der Innenhöfe

Die Innenhöfe der Bezirke Lend und Gries sind mit 23,38 bzw. 23,95 Prozent Bebauung die am stärksten bebauten Innenhöfe von Graz, gefolgt vom Bezirk Innere Stadt mit 21,82 Prozent. Der Mittelwert der Innenhofbebauung von allen Bezirken in Graz liegt bei 15,94 Prozent und lässt erkennen, dass die restlichen Bezirke klar darunter liegen. Die geringste Innenhofbebauung ist mit 4,08 Prozent im Bezirk Geidorf zu lokalisieren.

4.1.2 Bodenbelag

Die Versiegelung der Innenhofflächen durch Beton oder Asphalt ist in den Bezirken Innere Stadt und Lend am höchsten. Hier sind 20 Prozent der Innenhöfe zu mehr als einem Drittel versiegelt. Die geringste Versiegelung, in 53 Prozent der Innenhöfe sind unter 10 Prozent der Innenhoffläche versiegelt, ist im Bezirk Lend zu finden. Im Bezirk Geidorf sind 47 Prozent unter 10 Prozent versiegelte Innenhoffläche.

Der Wiesenanteil, also nicht versiegelte Fläche, liegt in allen Bezirken, außer Innere Stadt, über 41 Prozent der Innenhofflächen. Im Bezirk St. Leonhard ist der Wiesenanteil am höchsten. Bei 61 Prozent der Innenhöfe liegt der Wiesenanteil über 71 Prozent.

4.1.3 Vegetation Baum/Strauch

In fast allen Innenhöfen, ausgenommen Innere Stadt, sind Bäume zu finden. Den höchsten Wert weißt hier der Bezirk Geidorf auf. Hier wachsen in über 71 Prozent der Innenhöfe viele Bäume. Im Bezirk St. Leonhard ist der Bewuchs mit Bäumen ähnlich stark. Ähnliche Werte sind auch für den Bewuchs mit Sträucher festzustellen. So liegen wieder die Bezirke Geidorf und St. Leonhard im Spitzenfeld und der Bezirk Innere Stadt an letzter Stelle.

4.1.4 Verkehrsflächen

Im Durchschnitt sind in 39 Prozent der Grazer Innenhöfe Garagen vorhanden. Mit 53 Prozent gibt es im Bezirk Innere Stadt am meisten Garagen in den Innenhöfen. Autoabstellplätze sind durchschnittlich in 60 Prozent der Innenhöfe vorhanden. Diese Werte sind mit 83 Prozent im Bezirk Lend und 78 Prozent im Bezirk Gries am höchsten.

4.1.5 Aktive Nutzung der Innenhöfe

Die geschätzte prozentuelle aktive Nutzung der Innenhöfe durch Bewohnerinnen und Bewohner wurde anhand von bespielten bzw. brachliegenden Flächen geschätzt. Hierbei würde festgestellt, dass die höchste aktive Nutzung im Bezirk Lend vorhanden ist. Am wenigsten werden die Innenhöfe in den Bezirken St. Leonhard und Geidorf aktiv genutzt. Durchschnittlich wird bei 29 Prozent der Innenhöfe die gesamte Innenhoffläche aktiv genutzt.

5 DISKUSSION

Die Bezirke mit den größten Innenhofflächen in Gesamtflächen gesehen sind St. Leonhard und Geidorf. Dies deckt sich mit den beliebtesten Wohngegenden innerhalb der gründerzeitlichen Bezirke von Graz. [16]

Die Bereiche der gründerzeitlichen Blockrandbebauungen sind, wie in der Karte der Stadtklimaanalyse ersichtlich ist, die Bereiche, welche am stärksten von Überwärmung betroffen sind. Gründe hierfür sind die starke Bebauung sowie die windarme Lage von Graz, durch die es zu einer schwachen Durchlüftung kommt. Die Bereiche mit sehr starker Überhitzung decken sich mit den Bezirken Lend, Gries und Innere Stadt. Das sind auch die Bezirke, bei denen unter den Merkmalen die höchste Bebauung der Innenhöfe festgestellt wurde. Eine Bebauung der Innenhöfe wirkt sich negativ auf die Ventilation der Innenhöfe aus und erhöht somit die Temperaturen in den bereits als Wärmeinsel herausgestellten Bereichen. In diesen Bezirken wurden auch die meisten Verkehrsflächen festgestellt, was sich wiederum negativ auf die Emissionswerte auswirkt.

Die Versiegelung ist in den Bezirken Lend und Geidorf besonders gering. Dies hat jedoch im Bezirk Geidorf bessere Auswirkungen, da hier auch die Bebauung der Innenhöfe gering ist. Eine starke Versiegelung trägt zur starken Aufhitzung der betroffenen Stadtbereiche bei. Der Wiesenanteil, welcher eine nicht versiegelte Fläche darstellt, ist in allen Bezirken relativ hoch – außer im Bezirk Innere Stadt.

Der Baum- und Strauchbestand ist in den Bezirken St. Leonhard und Geidorf besonders hoch. Laubabwerfende Bäume verbessern die bioklimatischen Bedingungen und fungieren als Staubfilter. Begrünte Innenhöfe führen zu geringeren Maximaltemperaturen und erhöhen die Luftfeuchte, was wiederum zu einem behaglicheren Wohnklima beiträgt.[17] Somit ist es vor allem innerhalb der Wärmeinseln besonders wichtig, die Wohnqualität durch begrünte Innenhöfe zu verbessern.

[16] Stadt Graz, LQI Umfrage 2013.
[17] Laue, S. 46-47.

Obwohl die Begrünung der Innenhöfe höchstwahrscheinlich eine Auswirkung auf die Lebensqualität der Bewohnerinnen und Bewohner hat, ist eine aktive Nutzung der Innenhöfe im Bezirk Lend am höchsten sowie in den Bezirken St. Leonhard und Geidorf am geringsten.

Die größten Innenhöfe befinden sich im Bezirk Lend. Dies steht jedoch nicht in Relation mit der Innenhoffläche im Gesamten. Hier steht der Bezirk Lend an vorletzter Stelle. Das Ergebnis der durchschnittlich größten Innenhöfe lässt sich darauf zurückführen, dass es sich beim Bezirk Lend um den Bezirk mit den wenigsten Innenhöfen unter jenen, die für diese Arbeit herangezogen wurden, handelt.

6 CONCLUSIO

Durch seine zum großen Teil stark begrünten Innenhöfe innerhalb der gründerzeitlichen Bebauung kommt es in Graz zu einer Verbesserung des Mikroklimas in Bereichen der Stadt, welche als Wärmeinseln gelten. Ausschlaggebend hierfür ist eine geringe Bebauung der Innenhofflächen, da es nur so zu der gewünschten Zirkulation innerhalb der Blockrandbebauung kommen kann. Begrünte Innenhöfe tragen zu einer Verbesserung des Mikroklimas bei, da es vor allem durch Laubbäume zu zusätzlicher Beschattung in den warmen Sommermonaten kommt und sie auch als Staubfilter fungieren. Ein weiterer positiver Effekt stellt sich durch eine Erhöhung der Luftfeuchtigkeit infolge von Begrünung ein.

Die beschriebenen positiven Effekte lassen sich vor allem in den Bezirken Geidorf und St. Leonhard erkennen. Hier sind sowohl große, als auch zum Großteil unbebaute Flächen mit üppiger Vegetation vorhanden. In jenen Bezirken, die als die wärmsten Zonen von Graz gelten, ist hingegen eine starke Bebauung und weniger Vegetation zu finden, obwohl dies für eine Verbesserung des Mikroklimas besonders wichtig wäre. Somit kann klar von einer weiteren Bebauung der Innenhöfe abgeraten und zu einer Begrünung und Entsiegelung geraten werden.

How COVID Affects Decision Making in Planning? The Use of ICT in Planning Boards' Hearings

Nir Mualam

(Nir Mualam, Senior Lecturer, PhD, Faculty of Architecture & Town Planning, Technion- Israel Institute of Technology, Technion City Haifa 32000. nirm@technion.ac.il)

1 ABSTRACT

The purpose of this study is to examine the effect of COVID-19 on decision-making in planning. Put differently, how the shift to video-conference meetings has influenced the processes associated with land use planning.

We discuss this issue by looking at the shift of Israeli planning boards to online meetings. Since March 2020 decision-making has changed from face-to-face meetings between planners, public officials, and stakeholders to an online mode of decisions and meetings using a range of tools including, but not limited to Zoom and Teams. The lessons learned in Israel are relevant and applicable to other countries where similar shifts to online \ virtual hearings took place in 2020.

Everywhere, and globally, state and local governments have found new ways to enable the continuation of planning hearings and meetings; these remain uninterrupted, amid new requirements for social distancing. New laws enabled planning boards at the local, regional, and national levels to make decisions without meeting face-to-face. Notably, the Israeli regulations are but one example. In other countries, such as in the US and the UK, national and local governments have introduced similar policies and guidelines that enable, or even mandate, planning boards to shift their mode of operations to include online meetings -usually through ZOOM, TEAMS, SKYPE softwares (Thomas, 2020).

COVID19 has therefore had a major impact on the way planning is conducted around the world. These new regulations are important, as they have facilitated the continuity of policymaking in the field of planning. They also enabled planning boards to cope with their workload as no meetings had been held for months due to social distancing requirements.

The shift to online decision-making was praised by the professionals and media as rather successful (Steuteville, 2020), saving time, travel costs, and making planning more accessible via the use of Information and Communications Technology (ICT). On the face of it, COVID19, as a crisis, also held the promise of expediting the assimilation of technology in the planning process. It was therefore an opportunity to reconsider the way in which planning is carried out and to make it better, less bureaucratic, and more transparent.

To examine these issues, we initiated a survey among practicioners who participated in online (Zoom) meetings held by planning boards. In particular we ask:

- What do participants in online decision-making think about this new mode of communication? How satisfied are they?
- Compared with face-to-face engagements, what are the major pitfalls and advantages of online decision-making in planning?

The findings suggest that attendees is online meetings acknowledge the importance and advantages of ICT in facilitating planning discussions during the pandemic. However, they also flag some problems and challenges associated with this tool.

Keywords: virtual hearings, decision making, pandemic, Covid-19, planning boards

2 INTRODUCTION

2.1 Goal of this paper

The focus of this study is on the effects of COVID-19 on decision-making in planning. Put differently, how does the shift to video-conference and online meetings impact processes associated with land use planning?

The stage for this review is Israel, where national legislation made it possible for planning boards to switch rapidly to online meetings in March 2020 following the outbreak of COVID19. The government has found new ways to enable the continuation of planning hearings and meetings; these remain uninterrupted, amid new requirements for social distancing (Shahak, 2020). New laws enabled planning boards at the local, regional, and national levels to make decisions without meeting face-to-face. Notably, the Israeli regulations are but one example. In other countries, such as in the United States and the United Kingdom, national and local governments have introduced similar policies that enable, or even mandate, planning boards to shift their mode of operations to include online meetings -usually through a range of information and communication technologies (ICT) such as Zoom and Teams software (Thomas, 2020).

COVID19 has therefore had a major impact on the way planning is conducted around the world. These new regulations are important, as they have facilitated the continuity of policymaking despite the spread of the pandemic. Following, the objective of this study is to examine how COVID19 has impacted the planning bureaucracy. Specifically, its effect on the way in which decisions are discussed and reached. With respect to planning boards, the objective here is to analyze how – and if- the adoption of ICT platforms and mandatory requirements for online meetings has affected the planning process.

3 LITERATURE REVIEW

3.1 The death of distance

In the age of the COVID pandemic, a universal experience shared by people the world over has been the shift from commuting to workplaces and interacting in close proximity in the outside world to suddenly working remotely from home and interacting only over the internet. Prior to the pandemic, the word "Zoom" was likely only known in the business world as referring to a software used for conducting the occasional remote meeting. Nowadays, it has become synonymous with the current method of interacting, learning, and earning a living. Interestingly, while this shift from in-person to remote interaction has certainly been exemplified by the pandemic, it was foreseen as looming on the horizon as early as the 2000s.

In her seminal book, Cairncross (2001) observed that the rapid development of mass communication and the internet was bringing about a technological shift which would fundamentally alter the way we live and lead to what she termed the "death of distance".

In essence, distance would no longer be a key determinant of spatial organization in human relations and societies and would be continually rendered less significant. For example, workers gain the freedom to live farther from their employers who increasingly have to locate their services where key staff live rather than where the market is (Cairncross 2001, p.5-6). Such consequences, though still taking shape, appear to be liberating and democratizing as more and more people gain access to communications technology at a lower cost and are less restricted by distance. In this context, the proposed study intends to examine whether the death of distance can be tested in the field of land use planning (specifically- decisions made in the planning process). Moreover, we inquire whether bureaucratic shifts in decision-making ascertain and help cement the presumption about the death of distance.

3.2 COVID-19 as crisis and opportunity

Though Covid-19 has certainly thrown the world into crisis, some researchers see this as an opportunity as well. In having altered people's movements and patterns of work and leisure, scholars opine that it is time to rethink cities and the way we make decisions about them and about our land use. While existing research takes a stab at envisioning what the urban built environment post-Covid, most studies do not touch upon the way Covid has impacted planning and decision making nor the ways those decisions are made. If anything, this demonstrates the existing gap in the current state of knowledge regarding online decision-making and the way in which decision makers interact post-Covid-19. A major part of the literature such as that of Goode (2020) and Kim (2021) is concerned primarily with investigating how cities can prepare for and ensure their resilience in facing pandemics.

Lai, et al (2020) relate to COVID-19 as an opportunity for cities and urban planning. Indeed, they write, "The COVID-19 pandemic has opened up a crucial time-window of opportunity for urban scientists, planners and designers by unravelling before us the largest natural experiment in multiple aspects of urban activities and population mobility." (Lai et al, 2020 p.3). As well they also acknowledge the role of technology in the pandemic, noting that "Surveillance and contact tracing are key to fighting COVID-19 pandemic. Lai et al. however, do not tie technology to the form of decision making in planning and do not focus on how technology changed the way decision makers come together and deliberate planning matters following the pandemics. This issue also accentuates existing knowledge gaps: key scholarly contributions (e.g. Grant 2020; Ahmadpoor & Shahab 2021) are primarily concerned with how cities can prepare and make themselves resilient in the face of pandemics. They do not relate to online decision-making nor explore the way in which decision makers interact post COVID19. This paper fills these existing gaps in the literature.

3.3 Hyper connectivity in the workplace and COVID 19

The introduction of ICT technologies has been responsible for reshaping the way people interact, collaborate, and even think. This shift was already well underway even before the Covid era and was made even more acute as a result. Prior to Covid-19, many governments worldwide were in various stages of adopting ICTs in order to pivot towards 'e-government' - the full digitization of the public sector for delivering services to citizens more efficiently and transparently, and making these services more accessible, user-driven, and proactive (OECD 2019). In this respect, Deloitte (2018) reports that as the available array of new communications tools continually expands, they stand to make workers and their workplaces more connected, efficient, and productive. Many companies have begun to use these technologies such as videoconferencing and chats to restructure horizontally into a more networked team format (Deloitte, 2018. p.81). Indeed, Deloitte presents data showing that face-to-face meetings and phone meetings are declining in favor of work collaboration platforms (Deloitte, 2018 p.82).

Indeed, Quiggin (2020) suggests that preliminary figures show the pandemic has provided as opportunity to experiment with workplace productivity from home. Given that most workers spend an hour commuting to and from work on average daily, the time saved by working remotely could add up to a significant gain in productivity for the labor force as a whole (Quiggin, 2020). This view is echoed by Maurer (2020), who reports that initial skepticism of remote working has been largely diminished. Citing a survey of over 800 employers, Maurer writes that productivity has been shown to be "the same as or higher than it was before the pandemic, even with their employees working remotely" (Maurer, 2020).

However, there is growing concern in the corporate world that these new tools may actually harm productivity by subjecting networks of teams attempting to collaborate to an unending whirlwind of constant emails, videoconferences, and messages. This is especially true as research shows that people's communications habits and tools from their personal lives are infiltrating their work lives. (Deloitte, p.81). In the same vein, the Economist Team (2020) reports that the shift towards collaborative, remotely-based working brought about by the pandemic has not been liberating for workers, but instead has only increased the amount of work and the intrusion into people's lives.

3.4 Hypotheses

The foregoing analysis suggests that planning boards may encounter difficulties and quite a few challenges while applying this mode of communication and collaboration. Thus, we make several hypotheses based on the literature. These hypotheses relate directly to the research questions listed above: Hypothesis 1: The shift to online meetings by planning boards has had both positive and negative impacts on decision-making. Hypothesis 2: Participants prefer online meetings to face-to-face meetings.

4 METHODOLOGY

Following the data gathered through exploratory interviews and the literature review, we compiled a structured survey designed to answer key questions. The survey was disseminated among decision makers and other participants in planning board meetings at the local, regional, and national tiers of government. We sent the survey to experts, consultants, landowners, and community members who have participated in online meetings. Overall, 182 respondents answered the survey's questions.

Figure 1 depicts the division of respondents' opinion of the suitability of online meetings in facilitating discussions on planning and land use issues. Here the opinion is largely (but not overwhelmingly) in favor of using online meetings for this purpose at 67% (48% responded suitable and 19% very suitable). Roughly a third of respondents were of the opinion that online meetings are unsuitable vehicles for facilitating planning discussions. It is possible to interpret these results in a variety of ways in light of the literature reviewed in this paper. On one hand, it could be said that the majority that expressed faith in the online meeting format confirms the view of researchers such as Milz & Gervich (2020) that virtual participation is a real alternative

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

to in-person planning boards' meetings. On the flipside, the fact that almost one-third of respondents disliked online meetings could be said to validate the warnings of Milz & Gervich who point out the negatives such as loss of visual cues and the lesser degree of sincerity and comprehensibility.

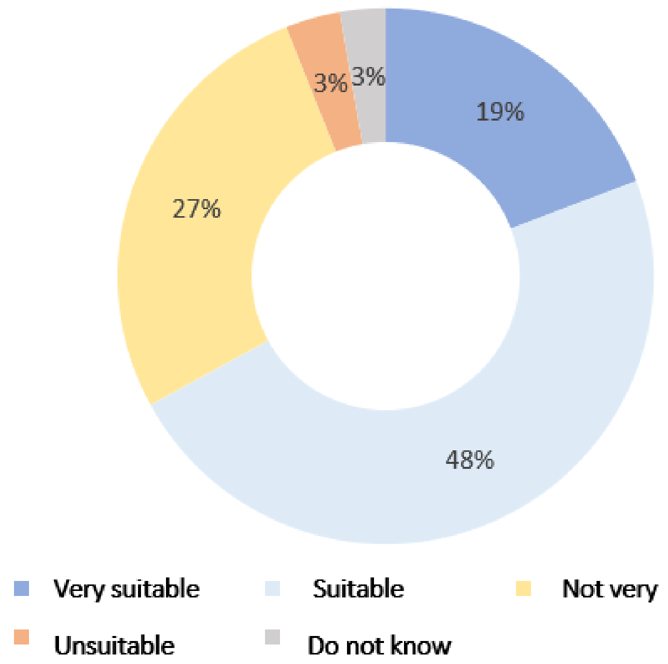

Fig. 1: Are online meetings suitable for discussions over planning and land use issues? (n=182)

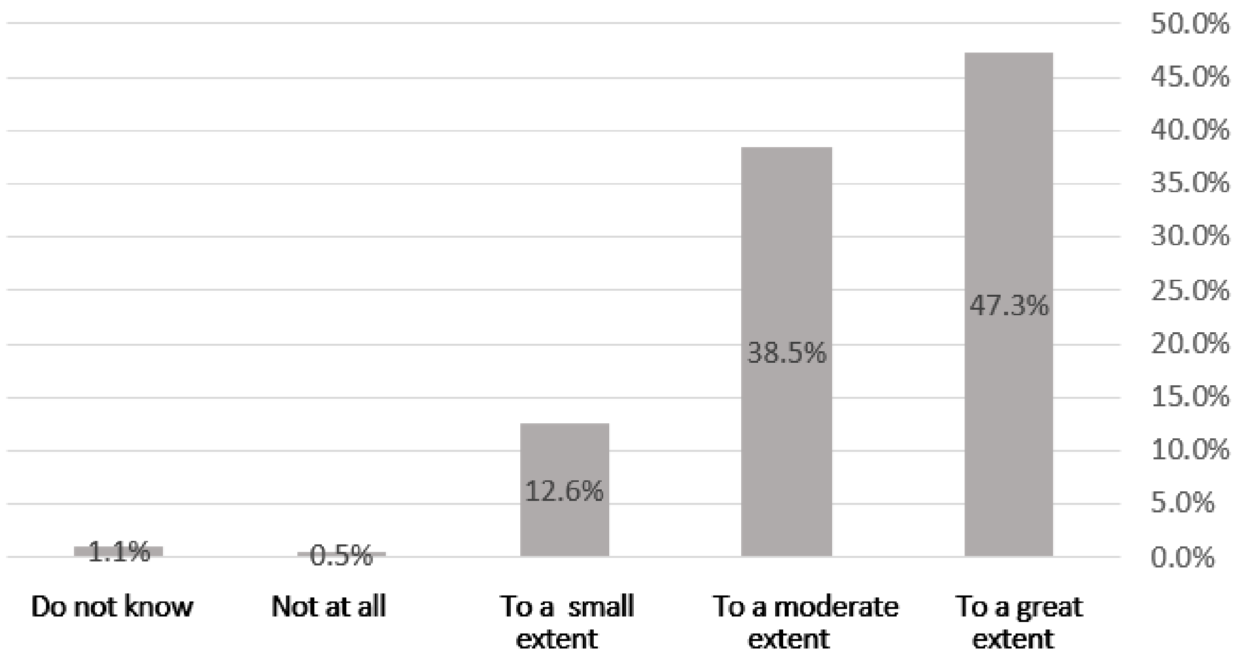

Fig. 2: Are online meetings suitable for discussions over planning and land use issues? (n=182)

Figure 2, curiously shows that the overwhelming majority of respondents (85.8%) felt satisfied that ICT can help attendees to express themselves in these virtual meetings, with a very small majority feeling they were barely or not at all able to express their views. With such a large percentage of respondents satisfied that they were able to express themselves in virtual planning meetings, it seems that such exercises in decision-making are occurring in line with the prescriptions of Sager (2018) and Davoudi (2018) for open communication, and the bringing together of many viewpoints and interests within the complex process of planning.

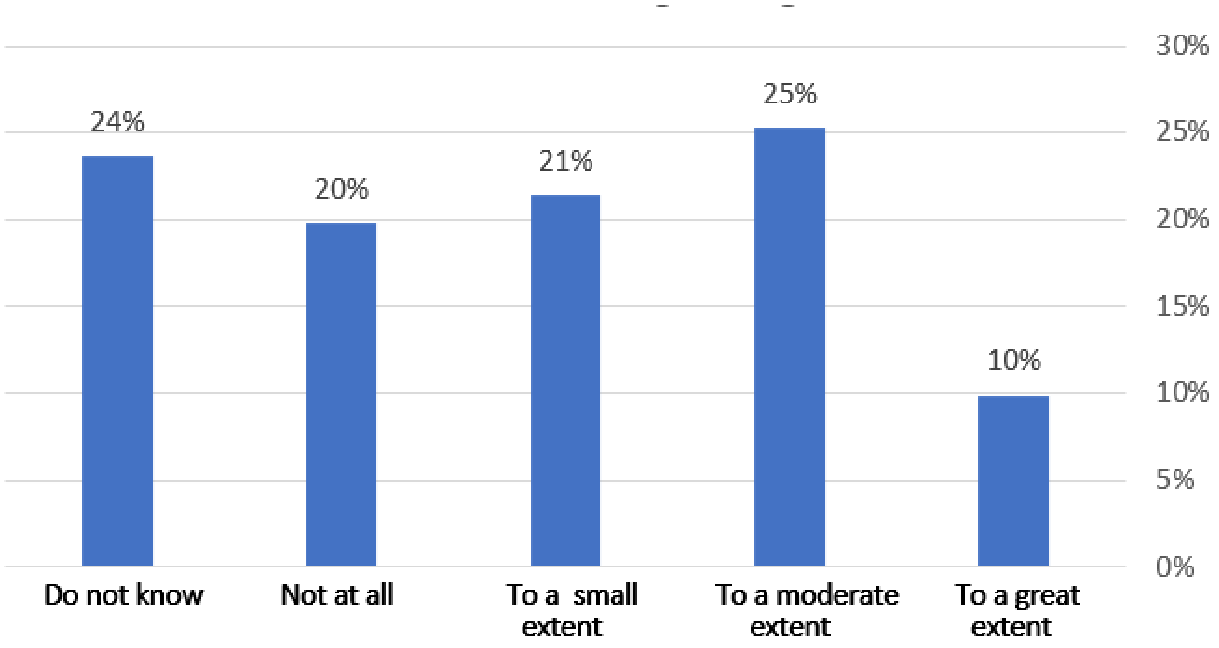

Fig. 3: To what extent did online meetings enable participants to build trust during hearings? (n=182)

The issue of trust in policy studies is quite complex. Many indicators are used in planning literature to measure trust. Survey respondents were asked about the relationship between trust building in the planning process and the use of ICT. Figure 3 displays the fact that respondents were strongly divided when it came to their opinions of the ability of virtual meetings to enable the building of interpersonal trust. This may be explained by the assertion of Willson (2000), who found that compared to face-to-face meetings, online discussion is usually rated lower by participants in several categories, among them the sincerity of the speaker. A further explanation may be the fact that according to Milz & Gervich (2021), the loss of visual communication cues in a virtual meeting may result in increased levels of disagreements and conflict. With more conflict and disputes occurring, it would be no surprise then that trust would suffer in the process.

As planning is a process involving stakeholder of varying backgrounds and interests, the idea that trust is lacking in virtual meetings is a worrying indicator for its potential to lead to facilitate virtual decision-making in land use planning.

Following, we asked respondents what are the major advantages of virtual hearings, compared with face-to-face engagements. Respondents mentions several key factors that make virtual meetings before planning boards more advantageous, including: the ability of ICT to allow more people to attend; the ability of virtual hearings to facilitate more polite discussions among participants; the ability to save time in arriving to meetings; and the ability of virtual hearings to accelerate change in government.

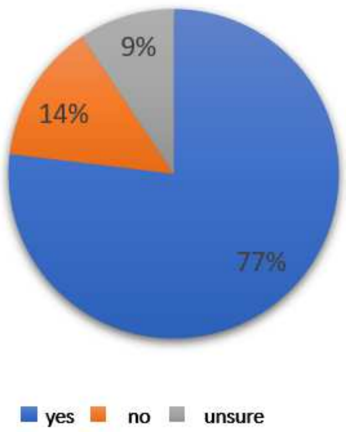

Fig. 4: Do you believe planning boards should continue using virtual meetings post pandemics? (n=182)

Respondents were also asked whether, after the pandemics, planning boards should continue utilizing ICT to facilitate online, virtual, hearings, at least as another option for deliberations. Respondents were quite adamant in their view that virtual meetings by planning boards should remain an option in the planners' toolkit (Figure 4). These findings bear out the views of several authors such as Gladovic et al (2020), Shapira & Youtie (2001), and Milz & Gervich (2021), who wrote that virtual participation vis ICT usage can be viable alternatives to face-to-face meetings given the many advantages afforded.

5 CONCLUSION

The study yields some insightful perspectives into how COVID19 has influenced planning decision-making. Results shed light on the challenges of using ICT technologies; the capacity of online decision-making to ensure the flow of planning decisions, to improve engagement and to accelerate technological change in government. In particular, the findings point to the positives and limitations of moving decision-making to online platforms.

6 ACKNOWLEDGEMENT

The author would like to extend his gratitude to Mr. David Max for his assistance throughout this study.

1 ABSTRACT

We are currently faced with a variety of serious crisis: climate, health and migration, all of them deeply interwoven. And all of them particularly apparent within the dense city structures. Urban open space becomes - once more - crucial in facing the accompanying negative effects like rising heat, density and infection. Evidentially green and blue infrastructure provides a cooling effect, a qualitative life space and a healthy environment – considered in a holistic and large-scale view guaranteeing good living conditions throughout the city. Before the background of urban densification the streetscape holds a huge potential in this regard. The street system forms a stable network of open space defined by building structure. It is entirely publicly owned and thus more easily accessible to public authorities for the immediate development and implementation of necessary measures. Furthermore, a change in mobility patterns is to be expected, that will initiate a debate about new functions of the street system. Last but not least, a variety of studies indicate, that the desealing of surfaces and the integration of trees and other vegetation - including green facades - offer a particular climate adaptation potential especially within the streetscape.

Although within the scientific society and politics well-known, the implementation of green and blue infrastructure measures is confronted with a variety of barriers - starting with administrative, technical and legal frameworks but also to a great part through missing awareness of and acceptance by neighbours and local stakeholders. This paper focusses on the latter presenting supportive processes and actions which are needed for transforming existing urban structures towards climate resilience in this regard. The findings are based on lessons learned in the Smart Cities Demo project LiLa4Green (Accompanying Living Lab for the implementation of green-blue infrstructure measures in the Smart City Vienna, 2018-2021).

LiLa4Green focusses on the visibility and traceability of the additional value of potential green and blue interventions within the streetscape opening up the discussion and mutual learning with the diverse involved parties on site. Main goals set are a) to cooperatively highlight existing challenges and elaborate potentials of green and blue design measures on site; b) to literally show options of participatorial developed interventions within the streetscape by effectively implementing commonly accorded small-scale measures; and c) to visualize potentials and alternatives virtually by means of an AR tool to enable low-treshhold participation in an early planning stage and to raise awareness for the topic. Multifold methods such as potential analysis, design studios, climate measurements and simulations have been applied to accomplish these goals - accompanied by a continuous Living Lab process on site.

In the course of LiLa4Green several barriers and restrictions but also potentials for making existing urban structure more climate-resilient became evident. All in all, the project managed to start a transition towards climate resilience in one of the densly built areas of Vienna. Three key elements proved to be essential 1) find solutions which fit to the local setting and set concrete actions 2) raise awareness and involve local networks, stakeholder and neighbours and 3) embed measures and demonstrations into a continuous process.

Keywords: urban structure, climate adaptation, green-blue infrastructure, living lab, public space

2 INTRODUCTION

The Paris Agreement, which entered into force in November 2016 (UN, 2015), has been a milestone in global climate policy stressing protection and adaptation as equally important and strenghtening the efforts of countries world-wide to achieve their climate targets. Likewise, Austria committed itself to the agreement and even strives for climate neutrality by 2040, intended trough the preparation of an amendment to the Climate Protection Act. This will mean a great effort in all sectors and at all scales. Action is urgently needed as the impacts of climate change are already tangible, especially within the dense urban areas due to urban structure and materiality. Natural surface has largely been replaced by sealed cover and building sites, that multiply the amount of heat storing materials in the third dimension.

Besides climate change, growing cities such as Vienna are currently faced with additional serious crisis such as health and migration, all of them particularly apparent within the dense city structures and deeply intervowen. Urban open space becomes - once more - crucial in facing the accompanying negative effects like rising heat, density and infection. Before the background of urban densification the streetscape holds a huge potential in this regard. The street system forms a stable network of open space defined by building structure. It is entirely publicly owned and thus more easily accessible to public authorities for the immediate development and implementation of necessary measures. Furthermore, a change in mobility patterns is to be expected, that will initiate a debate about new functions of the street system. Cities and settlements that are no longer designed to be “car-friendly” but “more human” and designed for active mobility improve social contacts, well-being and health (APCC 2018). Last but not least, reduced car traffic opens space for unsealing and greening. A variety of studies indicate, that the desealing of surfaces and the integration of trees and other vegetation - including green facades - offer a particular climate adaptation potential especially within the streetscape (Demuzere et al. 2014, Hagen et al. 2014, Stangl et al. 2019, Reinwald et al. 2019). Evidentially green and blue infrastructure plays a decisive role for the quality of life in cities by providing a healthy environment for recreation, a cooling effect reducing the heat island effect and by increasing the biodiversity (Reinwald et al. 2019).

Due to advancing climate change and the manifold benefits of green and blue infrastructure, many cities have already developed strategies and are setting measures for realizing climate resilient and green urban structures. The city of Vienna was one of the first which committed itself to a strategy for counteracting the UHI (e.g. MA22 2015). Vienna is also one of 15 European cities in the “Deep Demonstration” program (based on the EU initiative EIT Climate-KIC), which aims to network and support cities and regions in order to promote climate neutrality. But not only Vienna, also numerous medium-sized cities such as Graz and Linz, and even smaller cities such as Weiz, Kufstein, Perchtoldsdorf or Traiskirchen are actively committed to climate change adaptation and climate protection. The realization of green-blue infrastructure measures will be key for a successful realization.

However, the implementation of green and blue infrastructure measures is challenging as it addresses various urban issues (green and open space, traffic and pipeline infrastructure, water and sewage infrastructure, etc.) and stakeholders (Tötzer et al. 2019). Greening measures are confronted with a variety of barriers - starting with administrative, technical and legal frameworks but also to a great part through missing awareness of and acceptance by neighbours and local stakeholders.

The lessons learned from the Smart Cities demonstration project LiLa4Green[1] (Accompanying Living Lab for the implementation of green-blue infrastructure measures in the Smart City Vienna, 2018-2021) presented in this paper illustrate supportive processes and actions which are needed for transforming existing urban structures towards climate resilience. In the course of the project it became evident what it takes to realise green-blue infrastructure projects (urban green and urban water areas) in a densely built area of the city of Vienna (Tötzer et al., 2019). The project has been carried out by an interdisciplinary project consortium consisting of partners in the fields of planning, participation and communication, landscape architecture, climate modelling and software engineering. The central approach applied was a Living Lab, which has been set up throughout the entire project duration for involving citizens, stakeholders and decision makers in the implementation process. The Living Lab aimed at building a co-creative environment, raising awareness for the positive effects of green-blue infrastructure measures and increasing the acceptance and willingness to implement and invest.

[1] LiLa4Green is funded by the Climate and Energy Fund and implemented under the “SMART CITIES – FIT for SET” programme.

3 LILA4GREEN SET-UP – THE LIVING LAB PROCESS

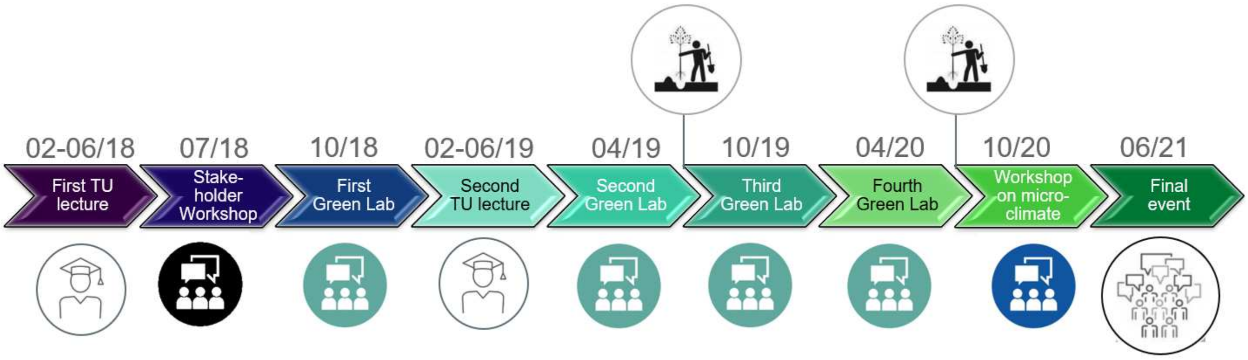

Fig. 1: Structure and timeline of the LiLa4Green project

The Living Lab (LL) structure worked as a framework for the entire project so that the basic structure of the LL had to be defined in the very beginning (Fig.1). Basic characteristics have been identified which are crucial for the success of the LL process: openness, realism, empowerment, spontaneity, sustainability and value as well as the local context. As the Living Lab aimed at the cooperative development of resilient solutions for the urban common ground (the streetscape) in a changing climate the involvement of local inhabitants and stakeholders at eye level was a key factor of success. Therefore the research team of LiLa4Green collectively formulated basic principles for its specific "Urban Living Lab" (ULL) to be concerted at the very beginning of all common events. One key basic principle was that the ULL should aim at a cocreative process involving urban Stakeholders and local Citizens to work out new products, services, technologies and social innovations in an experimental way (Fig. 2r.). The ULL therefore should aim at finding sustainable solutions for climate change adaptation measures in the urban open space by keeping the user in mind at the same time. The ULL should work as a eye level planning system and an alternative to top down city planning strategies.

After the defintion of the ULL characteristics a basic lay-out of the workshops had been designed. The core elements of the LiLa4Green ULL were the "Green Workshops" (GW) which were held on site and worked as different stages of envolvement. These workshops consisted of five steps towards a cocreative process of changing the local environment. The first step was taken hosting a "start-workshop" where local and city-wide stakeholders were invited to discuss the setup of the project and share their knowledge with the research-team and each other. Based on this interrogational setup the project also invited the participating stakeholders to involve themselves in the further steps (see below GW#1 to GW#4) as well as to formulate potential questions which could be answered throughout the LiLa4Green project. In this way the stakeholders where motivated to stay involved within the project also taking part within the following GWs. To find the right tool-set for the different workshops a screening of methods has been undertaken. 15 participatorial methods where collected and screened for their adaptiveness onto the layout of our ULL. This pool of methods was used for the design of the upcoming workshops each based on the respective foregoing event.

Preliminary to the GWs the neigbours had to be informed and their interest to involve themselves had to be raised. Therefore a set of methods was created to reach out on the public on different levels. Besides the classical communication strategies of posters, flyers and spreading these through multipliers, on-street campaigns were set up. Using transport-bikes and folding-chairs the passers-by were being informed and asked to interact (Fig. 2l.). As one interactive element they were asked to put flags on the perceived "hottest" and "coolest" spots within the research area. These spots were documented and continuously updated in a digital map on the project website (Fig. 4r.).

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Fig. 2: On-street activation in the case study area “Quellenstraße Ost” (l., ©PlanSinn_Brossmann) and co-creative design process within GW#3 held at Stadtraum in 2019 (r., ©PlanSinn_Meinharter).

Alltogether four “Green Workshops” where defined as linear events following a red line of interaction between the research team, the stakeholders and the neigbours. As it was planned in the setup of the framework to react on the outcomes of the GWs for the design of the oncoming workshops a basic flexibility in the structure and content of each meeting was taken into account.

The first “Green Workshop” (GW#1) was defined as an “exchange of knowledge” involving the participating neighbours as experts of their local district. The setup of the event was a “marketplace of ideas”, in a first step presenting the topics of climate change, open space usage and adaptation strategies on the base of the potential analysis (see chap. 4) by the research team and in a second step collecting the neighbour’s information on the surrounding urban open space and its interaction with everyday life in form of table discussions. The GW#1 concluded in a collective discussion highlighting amongst other findings the participating neighbours’ demand for an exemplification as a first step to be done to visualize possible changes in the streetscape.

The second “Green Workshop” (GW#2) aimed at finding first steps. On the one hand this workshop worked as an intersection between the intended design studios at the TU Wien and the Living Lab by offering a collective decision process. The GW was therefore defined as collective jury where students presented and discussed their ideas for a green-blue design intervention and the participating citzens could vote for their favorite design to be actually realized within the streetscape on site (Fig.3). Crucial for the success of the collective decision was a high correspondance of elected design and realized implementation requiring a lot of effort by all people involved (see chap. 5). On the other hand the GW#2 used the collective knowledge for testing the AR tool to be developed within the LiLa4Green project. The participants could vote and comment on the usability and effect of the presented web-based AR tool giving valuable feedback for its further development e.g. in changing to an AR app (see chap. 6).

Fig. 3: Participants of the GW#2 with the elected favourite design (©PlanSinn_Schopper).

The third “Green Workshop” (GW#3) served for identifying potentials in the urban open space. Based on the design implementation a lot of trust was built up between the participants and the research-team opening way to the next step. The GW#3 aimed at a co-creative design process for the complete research area by means of a specifically tailored game in divided groups. In the first phase the participants could playfully decide on and create adaptation activities based on given information on climate simulations and all other data collected in the project beforehand. In a second phase the participants had to take decisions within their range of collected ideas regarding a limited budget forcing them to focus. At the end each group presented a map of negotiated adaptation ideas. This "plan of action" builds the framework for all further implementations and activities in the case study area. In this workshop also the further developed AR app was tested and the results of the comments by the participants were compared to the first step of the development. Therefore, the participants themselves could identify the development of the tool related to their comments in the GW#2.

Finally, the fourth "Green Workshop" (GW#4) aimed at a collective implementation of specific adaptation ideas. Due to the Pandemic this workshop - planned as a collective realization workshop - had to be transferred into a digital format. A ZOOM Meeting was held with different breakout rooms related to the identified actions from GW#3. Despite of the complicated situation two of the commonly accorded adaptive actions could be implemented in summer 2020 (see chap. 5). All of these activities were accompanied by a frequent news mail to keep all participants of the GW informed. Furthermore, an Explain Video was created and put on the project website to activate citizens to take part and / or comment on the further steps.

The Green Workshops themselves were accompanied by a survey process which was set up before GW#1 consisting of a pre- and a post-survey. The participants answered an online questionnaire at their first attendance and were invited to fill out a second one after the GW#4. The final results are expected at the end of the project.

4 HIGHLIGHTING CHALLENGES AND POTENTIALS

At the beginning it was essential to get to know the overall frame conditions and the case study area itself in detail. Starting point of this process has been an extensive analysis concerning the need for and potentials of green-blue measures within our case study area as well as a specific analysis of existing strategies of the City of Vienna regarding climate adaptation within the streetscape. Following the co-creative approach, the early involvement of citizens and stakeholders was essential to pick up local knowledge and to raise awareness for and acceptance of the following process on site (see chap. 3).

As a case study served the area of "Quellenstraße Ost" within the Viennese district of Favoriten - representative for a dense city structure with very high impacts of urban climate on the one hand and an urgent need for public green and open space due to the prevailing demographic and ownership structure on the other hand. The current climatic conditions were mapped using objective microclimate simulations of a typical heat wave day with ENVImet. To evaluate the model results perceived data from interviews on the streets have been mapped in personal heat maps and discussed within the GW#1 (Fig. 4).

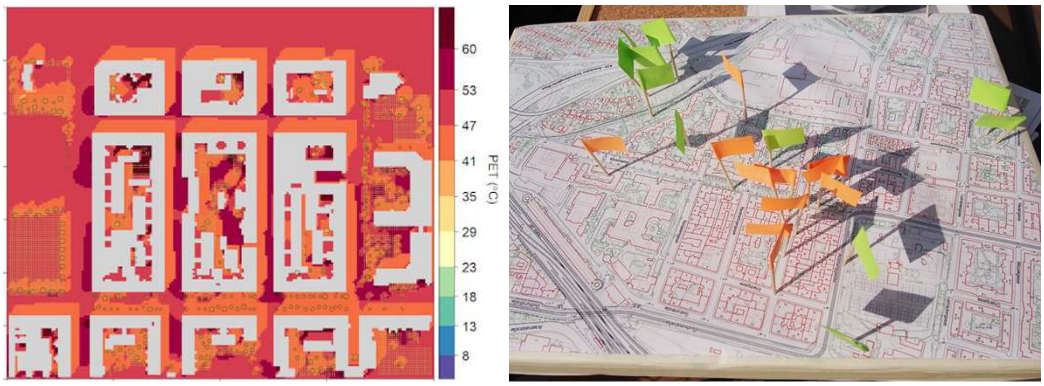

Fig. 4: ENVI-met simulation map on PET at 2pm (l., ©weatherpark) and personal heatmap of neighbours (r., ©PlanSinn_Matejka).

Previous to the potential analysis the intention was to analyse existing strategies of the City of Vienna to be able to tie in to concrete aims and measures already formulated within those papers. Main sources were the Urban Development Plan 2025 (MA18 2014) with its specifications "Green and open space" (MA18 2015), "Public space" (MA19 2017) and "Mobility" (MA18 2015) and the Urban Heat Island Strategy (MA22 2015). All strategy papers highlight the importance of urban green and open spaces in terms of ecology, urban climate and social relevance. The potential of street trees as well as the need for green links with a high quality of stay are explicitly mentioned. Through all strategy papers the streetscape as "urban and public open spaces that are accessible anytime for everyone and primarily in public ownership" (MA18 2017, p.6) stands out to hold the greatest potential for the transformation to green infrastructure within the urban

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

structure. The strategy papers have been scanned regarding the statements about the intersection of streetscape, green infrastructure and urban climate leading to consensual planning principles serving as important basis for the specific potential analysis within the study area “Quellenstraße Ost”. These consensual planning principles are: the greening of streetscapes with high quality of stay; creation of public and usable open spaces within the streetscape; creation of micro open spaces (Mikrofreiräume); upgrading of forecourts of public (education) buildings; completion of missing links within the urban green net; inclusion of semi-public and private green areas into the urban green net; inclusion of building related greenery such as facades and roofs; innovative temporary and multi-functional solutions; implementation of microclimatic design measures; awareness raising and involvement of citizens; rethinking and discussion of existing legal frameworks.

The consensual planning principles served as important basis for the subsequent analysis of potentials within the case study area “Quellenstraße Ost” (Fig. 5l.): The case study area is characterized by a very heterogenic city structure including large building complexes with generous greenery. Nevertheless, public green is limited to a single park in the very east. Green links are missing connecting with the recreation area in the east and the surrounding districts. The potential analysis highlighted potential green links inside (orange arrows) and outside (green arrows) the case study area regarding the future urban development and its consequences especially for the dense block structure in the north-west. It became apparent that this block structure (the so called “Kreta”) with its high percentage of sealed surfaces and missing greenery stands out as an isolated area with urgent need for action and a high potential for green-blue measurements. Furthermore, this area adjoins to several education buildings (orange) with high potential to upgrade the forecourts on the streets (purple stripes) including a feasible reduction of moving and stationary traffic (purple).

Besides the involvement of citizens and stakeholders also the involvement of students from Architecture and Planning as future urban planners has been an important issue within the LiLa4Green project structure. The first of two design studios held at the TU Wien had been set up within the analysis phase. Within “Grün’o’polis – grüne Wege in der Stadt” (WS 2018) interdisciplinary teams of 3 students each worked on the analysis of a wider area surrounding the study area of “Quellenstraße Ost”. Strategies and concepts had to be developed on a larger scale confirming to a great extent the potentials elaborated within the potential analysis. Further the students proposed first ideas of design measures on a block respectively street scale strengthening their concepts and giving an idea of how the streetscape could be developed in a greener and user-focused way. The results have been publicly presented on site followed by a poster exhibition that has been visited by neighbours, local initiatives, stakeholders and decision makers helping to raise the awareness, initiate a discussion and to foster acceptance for the topic and for green-blue design measures within the streetscape (Fig. 5r.).

Fig. 5: Potential analysis map of “Quellenstraße Ost” (l., ©TUWien) and poster exhibition of the design studio “Grün’o’polis” in the Ankerbrotfabrik in 2018 (r., ©Hagen).

5 IMPLEMENTING SMALL-SCALE MEASURE

An important result of the GW#1 had been the “demand for action” meaning the request of the participants to discuss based on an exemplification – is to say on a concrete implemented object instead of on mere theoretical aspects of potentials, visions and wishes in advance (see chapter 3).

The second design studio “Green up – cool down” held at the TU Wien tied in at this point. Master students from Architecture were to design ideas for a green-blue design element to be implemented within the streetscape of the dense block structure of “Kreta”. Important aspects have been the transparent process on site, the involvement of neighbours and local initiatives at an early stage, a precise framework for the design and the collective decision of which idea would be effectively built and implemented. The design course was held during the whole process in the Stadtraum am Kempelenpark opened for the public and on its corresponding terrain. Several inputs and workshops have been held for the students involving also local initiatives such as the Materialnomaden dedicated to the reuse of construction material. The specific guidelines for the design included: the layout of a parklet on two parking-lots within the focus area regarding all legal constraints necessary for the approval of implementation; the integration of green-blue elements; a modular system enabling the construction, deconstruction, storage and reconstruction of the design element; consideration of social aspects resp. multifunctional use; proposal of location and adjacent cooperation partner for stewardship and irrigation; costs within the budget of the funding programme “Grätzloase” by the City of Vienna. The 9 final designs have been publicly pitched and put to the vote during the GW#2. The living lab decided on the project “Follow the water cycle” by Jana Faraj Allah and Mais Msto that has been further developed and effectively implemented in summer 2019 on the Randhartingergasse by the whole student collective (Fig.6l.). As local partners served the Stadtraum am Kempelenpark together with the Egyptian Culture and Music Association directly adjoining the parklet.

Fig. 6: Parklet “Green up – cool down: Follow the water cycle”, Randhartingergasse in summer 2019 (l.: ©Grätzloase, r.: ©KLIEN).

The implementation process itself enabled further involvement of the neighbours and local partners in the set-up and maintenance of the design object. The parklet has been used by the direct neighbours and passers-by fostering its appropriation e.g. in form of gardening and gathering. A discourse has been initiated as well on additional benefit as on existing disapproval – the latter without any vandalism during the entire summer. Altogether the intervention can be considered as very successful resulting in concrete interests in “adopting” the parklet in 2020 and in the impulse for additional parklets within the district. Furthermore, the parklet has been recognized beyond the district by the Smart City Award 2018, as best practice for the Grätzloase and within the initiative Children`s University (Kinderuni, Fig. 6r.).

Subsequent to the implementation of the parklet the GW#3 aimed at an intense discourse on further potential green-blue design measures within the study area “Quellenstraße Ost” (see chapter 3). The Erlachgasse turned out to be an important starting point for implementation including a desired micro space at the entrance of the language school at the corner of the Absberggasse, an artistic green intervention at the crossing at Randhartingergasse and a temporary collective street-event. The choice of the Erlachgasse confirms the findings of the potential analysis highlighting the significance of this street as connecting pass and living space.

Despite of the unpredicted Corona situation - hindering the planned face-to-face exchange and cocreation with the neighbours – LiLa4Green achieved the implementation of the two desired design interventions in summer 2020. The parklet has been submitted and reconstructed by the language school Eurasya on two parking lots in front of their entrance in the Erlachgasse (Fig.7l.). In the meantime, they achieved a permanent permission guaranteeing a micro space during the entire year serving as common open space for the students and passers-by as well as for the children of the adjacent kindergarten. With respect to the artistic intervention the artist and landscape architect Hannes Gröblacher designed a temporary “magic

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

carpet" of grass floating above two parking lots at the crossing Erlachgasse/Randhartingergasse (Fig.7r.). The magic carpet has been publicly inaugurated in September serving neighbours and passers-by as urban green lounge. Both interventions initiated again a discussion on benefit and disapproval continuing the desired process of discourse and awareness raising.

Fig. 7: Reconstructed parklet in front of the language school (l.) and the magic carpet (r.), Erlachgasse in summer 2020 (©Hagen).

After summer, the magic carpet has been moved within the study area to the courtyard of the primary school opposite of the Stadtraum at the crossing of Kempelengasse and Quellenstraße. In summer 2021 a further design intervention will be implemented in cooperation with the primary school – once more in cocreation with the artist and landscape architect Hannes Gröblacher. The dead-end street in front of the school's entrance will be temporarily redesigned giving the impulse for permanent change into a green forecourt and public open space. The potential analysis highlighted this street section as one of the hot-spots for the implementation of green-blue infrastructure measures - also regarding the Viennese strategy to improve the forecourts of education buildings.

6 ENABLING LOW-TRESHHOLD PARTICIPATION BY VISUALISATION

An additional ambition of the LiLa4Green project was the elaboration of an alternative and innovative form of participation tool to enable low-threshold participation in an early planning stage and to raise awareness for the topic. Different ideas for measures to increase awareness and participation of stake-holders and inhabitants were discussed and refined. A broad range of possible measures were identified, ranging from electronic tags for marking hot areas in a street, to a heat simulation tool for explaining effects of heat in cities and finally to an augmented reality (AR) app for visualizing greening and cooling measures in a realistic way. A selection process of the project team favoured the augmented reality app with the reasoning that an innovative technology would possibly raise more awareness than other lower technology approaches.

The basic idea of the augmented reality app is to project 3D modelled objects of a greening project (like trees, water ponds or built design interventions) at exactly the same position where the measures would be placed in the real world. Participants would be able to observe the measures and even walk around and interact with the objects using the AR tool. In advanced applications, the participants can be invited to vote and comment on alternative options for a greening project.

A first implementation of the augmented reality application was designed with the goal to have a very low technological barrier for installing and using the app. This resulted in a browser based augmented reality solution. A test with participants during the GW#1 proved the assumption correct that such an application raises awareness of the topic, however, it also showed that some participants were more concerned with issues of the app on their personal mobile phone than with the topic itself. Also, it became apparent that the selected technology was not sufficient to provide a gameful user experience since the users could not freely walk around the projected AR objects (Fig. 8l.).

Those observations together with the feedback of the participant lead to a new implementation with modified requirements. It was decided to use special hardware devices for the AR application (iPads with Lidar sensors) in order to provide a high level and playful AR experience. This increases the barrier of use, but it allows the participants to focus on the topic and not on installation issues on their mobile devices.

Fig. 8: Testing of the browser-based AR tool in GW#1 (l., ©PlanSinn_Schopper) and of the advanced iPad-based AR tool in GW#2 (r., ©GrünStattGrau_Formanek)

The new version of the AR application was made available in the Apple application store under the name L4G AR Viewer and was tested during two different events. Prepared iPads were given to the participants together with explanations of the planned greening measures, resulting in more vivid discussions and interactions between Living Lab staff and participants (Fig. 8r.).

During the finalization of the tool for the app store, a new functionality was added which allows the use of the application without any preparation of models and markers. In this basic mode, the app allows the planting of virtual trees in streets and on sidewalks. Screenshots of those planted trees can be shared with other persons. This mode can be used to raise basic awareness of the greening topic, especially with younger persons. First tests using this functionality are scheduled with school kids throughout the end of the Lila4Green project.

7 CONCLUSIONS

In the course of LiLa4Green several barriers and restrictions but also potentials for making existing urban structure more climate-resilient became evident. All in all, the project managed to start a transition towards climate resilience in one of the most densely built areas of Vienna. Three key elements proved to be essential 1) find solutions which fit to the local setting and set concrete actions 2) raise awareness and involve local networks, stakeholder and neighbours and 3) embed measures and demonstrations into a continuous process.

To accomplish the associated aims for building a co-creative environment, for raising awareness for the positive effects of green-blue infrastructure measures and for increasing the acceptance and willingness to implement and to invest the following aspects appeared to be crucial:

(a) transdisciplinarity: to build up a sound base for decisions and actions a comprehensive scientific background is necessary. In the case of LiLa4Green this involved various disciplines and methods such as the potential analysis and microclimate maps.

(b) interplay between external impulses and local involvement: every external impulse can only be successful when locally accepted. Local involvement at an early stage guarantees awareness for and identification with implemented measures. This link is facilitated by the living lab.

(c) experiments: interventions are useful and important, because they are visible and tangible. Above all they initiate controverse discussions constituting a crucial step for involvement and for awareness raising. It is necessary though to install an accompanying communication process e.g. within a living lab.

(d) continuity in the process: it is essential to let the participating and observing people know that the process is still ongoing. This can be achieved through different channels such as newsletters, on site visits, websites and activities on site.

(e) low threshold participation: to gain the confidence and engagement of the involved parties it is necessary to approach all participants at eye level and to appreciate local knowledge. Low threshold tools should therefore be selected when preparing the process to foster successful participation.

(f) legacy of the LL: the living lab should be embedded into existing local networks in order to guarantee a continuity after the end of the research project. Within Lila4Green these have been the area renewal office, the Stadtraum on site, the collaboration with local partners such as the Egyptian Culture Association or the Materialnomaden, the language and primary schools and many more.

The Living Lab proved to be essential for framing the entire process and for embedding the various elements of the project (awareness raising, implementation of green measures, testing and co-development of AR tool, involvement&training of students and pupils, etc.). Making existing urban structures climate-resilient is a complex issue that requires the consideration of the specific local setting and the involvement of diverse stakeholders and actors. Thus, the process towards transformation is as crucial as the measures themselves.

The LiLa4Green project has been nominated as official IBA Candidate (International Building Exhibition Vienna 2022) and was part of the IBA interims-exhibition "How will we live tomorrow?" in October 2020.

1 ABSTRACT

Information communication simplifies the way of living as everyone is updated with everything happening around them. With technology, information distribution becomes more efficient and convenient, and everyone could have access to the same information which on most occasions is accurate. Globally, developed countries have implemented different techniques in information dissemination for public transport through technology which today these technologies are adopted in public transport everywhere in the world including developing countries. South Africa is a developing country that has numureous public transportation systems for commuting and with the City of Johannesburg (COJ) having all forms of public transportation available in the country. Currently, the city has various forms of public transport including both formal and informal public transportation such as ride-share services (uber and taxify), Bus Rapid Transit system (BRT) known as Rea Vaya, High-Speed Trains (HST) known as Gautrain system and traditional public transport systems (mini-bus taxis, Putco Bus, metro rail). This paper seeks to identify whether the high usage of ICT could assist to integrate both formal and informal public transport systems through different dynamics to deliver sustainable and convinience public transportation systems. The study adopted a case study research design and a mixed method approach that facilitated the gathering and analysis of both quantitative and qualitative data from the public transport officials and commuters. Statistical, content and document analysis were used to glean more information. Preliminary results indicated that Innovative formal public transportation such as Gautrain system, Rea Vaya bus, uber and taxify deployed the usage of ICT which makes commuters to be informed with the whereabouts of the innovative public transportation, however, commuters still struggle with convinient movement in and around the city due to numerous factors. Consequently, informal public transport such as mini-buses (taxis) which transport 60% of commuters daily in and around the city does not have the usage of ICT in any form but can be efficient at certain times and can also be frastruating at some times as there is no form of communication. The implications of the study indicate that the city has the high availability of public transportation which is disjoint from each other affecting reliabilty and efficiency for commuting as there is lack of formal information communication within these different public transportation systems as all of them are interested in benefiting individually. The study recommends a development of an integrated online application which will provide information on both formal and informal public transpotation plartforms in the City of Johannesburg for commuters to be able to be informed of the availability of public transport in the City for Johannesburg 24hours for conviniency. Further, this app could assist commuters to identify the movement of the innovative formal public transport in-real time to create seamless travelling if necessary, for commuters. With efficient and integrated public transport system in the city will result in more usage of public transportation.

Keywords: ICT, formal public transport, informal public transport, integration

2 INTRODUCTION

Contemporary public transportation systems are tailored towards improvement of mobility. Mobility infrastructural developments continue to be a necessity across all epochs of life, in light of this and the emergence of the fourth industrial revolution era, cities are investing on new innovative systems to improve connectivity. Within the South African context, the City of Johannesburg Metropolitan Municipality has implemented various innovative transportation systems. Currently the city has various forms of both formal and informal public transports such as ride-share services (uber and taxify), bus rapid systems (Rea Vaya) and high-speed trains (Gautrain), traditional public transport systems (mini-bus taxis, Putco Bus, metro rail).

To ensure synergies are shared between traditional public transportation and innovative public transport systems, the use of technology and big data which are now available and can be mined due to the emergence of the fourth industrial revolution are proposed. The objective of this paper is to identify a strategy to integrate the existing formal public transport with the informal public transport within the City of Johannesburg. As various modes of public transports serve a different purpose to different communities. The paper identifies the mostly used public transportation modes and assess the different information dissemination of the existing public transport. The integration of public transport will not only make trips faster but also safer since stations will be in close proximities and commuters do not have to travel long distances to catch another mode of transport.

3 LITERATURE REVIEW

3.1 Urban public Transportation

Cities and metropolitan areas are centres of diverse activities, which require efficient and convenient transportation of persons and goods. It is often said that transportation is the lifeblood of cities. Vuchic (2017) states that high density of activities makes it possible and necessary that high capacity modes, such as bus, light rail and metro, be used because they are more economical, more energy efficient and require much less space than private cars. Moreover, public modes of transportation provide service for all persons, while cars can only be used by those who own and can drive them (Nur & Gammons, 2019). Thus, cities need and benefit from public transportation services, which offer greater mobility for the entire population than people in rural areas can enjoy. Transit systems are also needed in urbanized areas to make high-density of diverse activities, such as residences, business offices, factories, stadia, and other activities physically possible, while keeping cities liveable and attractive for people (Vuchic, 2017). Urban Public Transportation is defined as a form of travel offered locally that enables more people to travel together along designated routes (Vassilis, et al., 2019). Typical examples of forms of public transportation include buses, trains, and in other countries trams, high-speed rails, airlines, and coaches dominate public transportation between cities. Most public transport services operate on stipulated timelines. Some transportation systems operate on a full capacity basis, which means the vehicle will not start until it’s full. However, many cities across the world provide shared taxis when the essence of time is a factor (Viergutz & Brinkman, 2018).

Urban Public Transport is a system that is used to serve all individuals moving from origin to destination and a certain fare should be paid for a trip taken (Lyons, 2019). Public Transport offers different kinds of service including the operation of a certain system depending on the service providers. Mostly, each and every system has start and end time, some operate 24hrs for example mini-bus taxis and ubers/taxify in South Africa, during the week and weekends operations are different, and these systems have certain intervals of operation(Zhong-Ren et al., 2012).

3.1.1 Bus rapid transit (BRT) system

When buses are physically separated, through some investment, from cars, this has become to be known as a Bus Rapid Transit (BRT) system. Basso et al., (2019) define the Bus Rapid Transit as a system with high-quality bus-based transit system that delivers fast, comfortable, and cost-effective services at metro-level capacities. It does this through the provision of dedicated lanes, with busways and iconic stations typically aligned to the center of the road, off-board fare collection, and fast and frequent operations” (Walters, 2013). Due to the BRT containing features similar to a light rail or metro system, it is much more reliable, convenient and faster than regular bus services. With the right features, BRT can avoid the causes of delay that typically slow regular bus services, like being stuck in traffic and queuing to pay on board (Basso, et al. 2019).

Buses represent the most widely used transit technology. Virtually every city in the world that has transit service operates buses. Large cities with rail transit also operate extensive bus networks, usually on lines with lower passenger volumes or as feeders to rail lines (Basso, Feres, & Silva, 2019). The BRT service is easy to introduce or modify, basic service requires only purchase of vehicles, garage and maintenance facilities, and organization of service. Stops along the lines can be simple (Ordóñez Medina & Erath, 2013). Therefore, buses represent the most economical transit mode for lightly travelled lines. This flexibility of bus routes is an advantage for any necessary changes, but it is a disadvantage for major bus lines: they lack permanence, efficiency in carrying heavy passenger volumes, and image of permanent, physically fixed routes desired by passengers(Basso et al., 2019).

Earlier, the public transport industry structure typically was of two types, the publicly owned monolithic companies that operated the entire system as in Paris, New York, or Moscow, or a collection of small private operators like in Lagos, Nairobi, and Bogota (Viergutz & Brinkman, 2018). However, the emerging industry structure is the one where a public entity determines the routes and schedules and contracts operations from private operators. This practice has become common in London (for its bus services), Bogota (for its BRT system), and a host of other cities. Such an arrangement allows the public sector to ensure that good public transport is available to all citizens and, at the same time, allows private sector efficiencies to be tapped for operations (Viergutz & Brinkman, 2018). However, such a contractual arrangement would not have been possible if technology had not permitted a detailed tracking of vehicles(Walters, 2013). The ability to track vehicles has made it possible to easily enter into fleet operating contracts as it is possible to monitor the implementation of the contract more effectively. Thus, it is possible to verify whether buses completed the entire journey, whether they were on time, and a host of other metrics (Luke & Heyns, 2020). This allows for contractors to be paid based on actual performance and also facilitates rewards and penalties for over- and underperformance. The BRT system is made possible through the implementation of ICT.

3.1.2 Uber and taxify

Uber is an application that connects passengers with drivers who have a contract with Uber (Contents, 2019; Coppola & Silvestri, 2019). To order a vehicle it is necessary to own a smartphone and to register within the mobile application by entering your name, e-mail address, a cell phone number and a credit card number that is to be billed automatically at the end of the ride. According to Pojani and Stead (2015), among the biggest disruptions in the current transport system has been the arrival of aggregator platforms that have allowed car sharing systems like Uber, Lyft, Didi, and Ola to emerge. Essentially, such platforms match the demand for trips to the supply of trips(Hensher, 1998). Passengers book for rides to travel from a certain point to another and the platform locates available taxis, or other vehicles that are available, and match the two. This has proved immensely convenient to both passengers and to taxi operators and is, therefore, disrupting the market. All this is possible through the employment of Information and Communication Technology. This was launched early in April 2016, the Delhi-based start-up provides people with an opportunity to share rides with others while also helping them reach their destinations faster and in a more cost-effective manner by reducing the waiting period for a cab or an auto by connecting a network of people who are driving on the same route (Basso et al., 2019). The app plugs the demand and supply gap between drivers and riders by allowing a person with seats to spare, be it in a car, an auto, or even a cab, to share his or her route online and connect with a person heading the same way using various route matching algorithms(Coppola & Silvestri, 2019).

Passengers can request a ride and if accepted by the pooler, it will direct them to the “pikup” point determined by the app. Once the ride is complete, a cashless payment process is initiated through card-less banking payments, further making the process less cumbersome by avoiding the hassle of change(Coppola & Silvestri, 2019). The entire operation is simple and allows a convenient way of traveling. The prices are also transparent and listed on the app in the form of rate cards that are fixed based on the distance covered. Walter (2013), alludes the entire process of uber makes it less expensive and auto rates since it is immune from surge pricing and other time-based charges. The app also allows a female-only option that matches female riders with seekers. There is also an SOS feature, where apart from a person’s registered contacts, Pikup will also receive a real-time update on a user's whereabouts through SMS and call (Basso, et al. 2019).

3.1.3 Minibus taxis

The minibus taxi industry which is mainly operated using 16-seater minibus taxis is responsible for providing public transport services to a significant number of commuters (Baloyi, 2013). This is due to network flexibility that this mode of transportation mode offers, it is more accessible than trains (rail transport) and, therefore, more intensely used. It is also much faster than the bus services as it does not operate on a fixed schedule (Binza & Siyongwana, 2012). Though the minibus taxi industry offers better services mentioned above the industry is not subsided by the government. Baloyi (2013) notes that the minibus taxi industry plays an important role in both rural and urban public transportation systems, both in mobility and economic terms. The industry employs a large number of people and circulates significant large amounts of money. Although the way the taxi industry is organized varies across countries and even within countries, some factors are shared at varying latitudes of the globe.

The biggest challenge with the integration of all public transportation is the resistance by taxi owners, operators and drivers (Machiavelli, 2019). These role-players are prepared to sabotage any development that that is meant to improve travel conditions for the general public. Just like every other capitalist, taxi owners are concerned with the generation of profit more than the improvement of the mobility systems. In that case, a system that will ensure profit for taxi owners and decrease in the usage of public transport needs to be put in place.

3.2 Information and dissemination

Information Dissemination is defined by Gkania and Dimitriou (2019) as an active distribution and the spreading of information of all kinds to the users or those audiences that deserve it. In developing effective dissemination strategies, plans and policies for public transport companies there is a need to understand the scope and characteristics of their current and potential users. Appropriate dissemination is a significant aspect in attaining user satisfaction and increasing usage(Koutsopoulos, Ma, Noursalehi, & Zhu, 2019). According to Pojani (2015), in the dissemination and utilisation processes five fundamental processes need to be analysed namely:

(1) User: the potential user of the product to be disseminated (NCDDR, 1996). The user is the receiver of information which can only be considered effective if the user is able to successfully utilise the information received to maximum satisfaction.

(2) Source: the agency, organisation or individual responsible for creating new knowledge or a product for conducting dissemination activities.

(3) Content: the knowledge of the product itself; an example in public transport content consists of travel times, routes, fares and timetables (NCDDR, 1996).

(4) Medium: ways in which knowledge is shared or the product described and packaged or transmitted, for example, SMS's, e-mails, mobile apps, public information displays and social media.

(5) Context: the way the product or knowledge is developed and disseminated, including contextual factors related to the source, the user, the content and dissemination medium (NCDDR, 1996).

There are typically great reasons why associations choose to disseminate information, they are normally related but can be categorised to underline the motivation and significance of effective information dissemination.

According to the NCDDR the following categories are reasons for information dissemination:

(a) Judgement: Information is disseminated with the expectation that individuals within an organisation will improve their knowledge and subsequently improve their judgements in future situations.

(b) Awareness: Information is disseminated with a specific end goal to teach, clarify and advance an idea, procedure or standard. For instance, technical stipulations explaining systems, capabilities, instruction about alternative transport to avoid congested routes, notification of train delays, are all ways in which information is disseminated (NCDDR, 1996).

(c) Response: information is often disseminated with the sole expectation that it will bring about some feedback that may require additional data to be created. Examples include advertising, questionnaires, market survey, etc.

(d) Collaboration: Information is regularly disseminated in order to share knowledge and ways of communication. Examples incorporate workflow systems to encourage the flow of information between systems in order to accomplish a common purpose, e.g. control systems where probes may identify and transmit notices about specific events (NCDDR, 1996).

3.3 Information and Communication Technologies ICT

There is no single universal definition of Information and Communication Technology (ICT), the term is generally accepted to mean all devices, networking components, applications and systems that combined allow people and organizations (i.e., businesses, nonprofit agencies, governments and criminal enterprises) to interact in the digital world (Agarwal et al., 2018; Azolin et al., 2020; Litescu et al., 2015). ICT applications aim to provide information through innovative services relating to different modes of transport and traffic management that enable various users to be better informed and make safer, more coordinated and smarter use of transport networks. The use of ICT guides and inform commuters how a certain public transport system works, and this information is provided in a portable manner.

The use of ICT in urban public transportation helps in allowing data to be compiled on the speed of vehicles in different parts of the city, or different sections of the road network, the time taken to move from place to place, the distance travelled, the points at which the vehicle stops and for how long and other important information for commuters (Litescu et al., 2015). This helps in getting an idea of the level of congestion at different points of time in the day and the choke points in the city that need attention. This also helps in planning routes and schedules on a more scientific basis. It also helps in monitoring driver and vehicle behaviour for corrective action. It provides information on the exact time at which a vehicle reached a certain place and the route it followed in moving from place to place. This allows contracts to be monitored and a verification of whether contracts terms have been met.

3.3.1 Social Media

In the 21st century, the use of Information and Communication Technology has revolutionised and subjects such as social media has transformed the way people interact and share information in essence the way individuals communicate. According to WeAreSocial (2020), there are 3.8 billion social media uses in the year 2020, these statistics might have increased during the Global corona virus lockdown across the world.

Social media platforms are defined as web-based services that enable people to disseminate and receive information in real time (Gal-Tzura et al., 2014). Social Media may be used for various functions such as promoting businesses, for customer relations and for real time information notices. For this reason, the use of social media grows day by day and various sectors have begun to take social media marketing seriously as they are able to reach a wider audience through this medium (Musakwa, 2014). Social media is utilised by individuals of different ages, nationality employment status and with diverse interests. The social media community comprises a rich sample of members which allows these platforms to be powerful tools that are suitable for collection of transport data, by surveys or other ways (Gal-Tzura et al., 2014). Social media can be seen as a tool that is used for transport related applications and transport companies use this platform to communicate with their users (Amey et al., 2011; Bregman, 2011; Gal-Tzura et al., 2014). The core purposes of social media use across organisations are information sharing and updates, advising the public on travel disruption, handling travel queries, and responding to queries and messages. The information posted by organisations includes updates on travel delays, marketing and promotion deals which is done to expand brands and to have direct interactions with users (GalTzura et al., 2014).

Transport companies also use marketing concepts such as “seasonal goodwill messages” sent to commuters and was seen on many of the sites. This was consistently informal in nature and seemed to be aimed at promoting the concept of timeliness, community and friendly service (Litescu et al., 2015). The magnitude of the organisation overall does not influence its use of social media. Large organisations do not necessarily use social media as a strategic tool. The transport sector and commercial sales sector will not utilise social media in the same way, each sector uses social media in various ways and one more than the other. According to Gal-Tzura et al. (2014) “the longer the social media sites have been established, the more likely the use becomes focused”. A trend for interaction was noted with some associations that use social media in a highly interactive way setting an example for other organisations (Litescu et al., 2015).

3.3.2 Mobile transport Application

While gaining knowledge about the main part of public transport trip might have been historically possible, information on the critical secondary connections was not. This was particularly the case in developing cities with limited, if any, formal, fixed route and schedule bus systems covering only a small part of the entire conurbation with service (Coppola & Silvestri, 2019). Today’s ICTs provide the ability to map the entire formal and informal public transport systems, providing passengers with a complete picture of travel options, from actual origins to actual destinations. That information can be made available anywhere, at home or work, at stops, stations and terminals, and even on-board. People need travel information for their trips from their origins to their destinations. It also helps reduce uncertainty for people making new trips. Public

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

transport systems typically focus on providing service information to the public. This information covers routing and stops, schedules, and fare payment.

Information Technology has developed over the years with internet connectivity and mobile devices presenting an opportunity to tackle private mobility (Speed and Shingleton, 2012; Dickinson et al., 2015). The availability of smartphones allows users to access travel information about their travel issues, to view where others might be in their social network and share information (Dickinson et al., 2015). Application developers have recognised this potential and as result there have been great developments in a range of apps that track users, share travel information and provide real time public transport information as they enable access to data resources that were once perhaps difficult to access (Litescu et al., 2015). Smartphones are the ideal travel instruments as they can be used on the move and to share and, access information on travelling (Dickinson et al., 2014). The trends of applications have been focused more on travel information and route planning. However, more recently transport companies have developed apps to facilitate a more collaborative use where commuters may purchase tickets in advance through these mobile apps and use their smartphones as tickets (Koutsopoulos et al., 2019). These apps assist users to join social networks and to make better use of their collective travel resources, thus potentially allowing users to be interactive on social media. Analysis of the collaborative travel apps currently available indicates that they operate according to various forms of exchange, each social app serving its purpose. Travel apps are unlikely to play a role in these settings through person to person connectivity of smartphones which makes them a useful facilitating tool (Dickinson et al., 2015).

3.3.3 Real time information dissemination

ICT has made it possible to locate a vehicle and also track its movement from a central control station. This has been possible due to a global positioning system (GPS) device being fixed to a motor vehicle and programmed to continuously communicate its location to a central control centre (Machiavelli, 2018). This information can simultaneously be communicated through specially developed apps to individual mobile phones. Similarly, GPS embedded on most smartphones allow the location of a person using that phone to be communicated to a central control centre, thereby allowing an assessment of the level of crowding in any area. The ability to accurately track a motor vehicle has led to many possibilities that were not otherwise feasible (Vuchic, 2017).

3.3.4 Public information Display

Public Information Display systems are defined by Vuchic (2017) as an automated system for supplying users of public transport with information about the nature and state of a public transport service, through visual, voice or other media. Public Information Displays are becoming very common in modern public transportation. Realtime information displays are prominent in the transportation sector. These systems show real- time information by providing features such as next departure of trains and buses at stations and stops (Machiavelli, 2018). Research has shown that this kind of information is appreciated by commuters and the installation of PIDs is to improve significantly traveller information and the quality of service. In evaluating PIDs, commuters often question their reliability and comprehensiveness (Dziekan and Kottenhof, 2007).

4 STUDY AREA

The City of Johannesburg is the focus area of study. The city is home to 7 regions and is the largest city in the country and contributor to the country’s GDP. The City of Johannesburg is the biggest contributor to South Africa’s economic growth and is also the most polluted city in the country as of the 2011 population survey (Stats SA, 2012). The city was founded prior to the discovery of gold which led to high employment of the South African populace through gold mines (Rand Refinery, 2013). The city is home to numerous townships, one of which is Soweto, the oldest and big township in the country.

The establishment of the gold mines in the area led to the flooding of South Africans from different provinces into the City of Johannesburg for “greener” pastures. This extended to neighbouring countries where people came into the city for mostly unskilled labour (Rogerson & Rogerson,2014). This led to a need for more public transportation, improved transport infrastructure in the city such as roads and railways which led to the improvement of public transportation, specifically the railway systems.

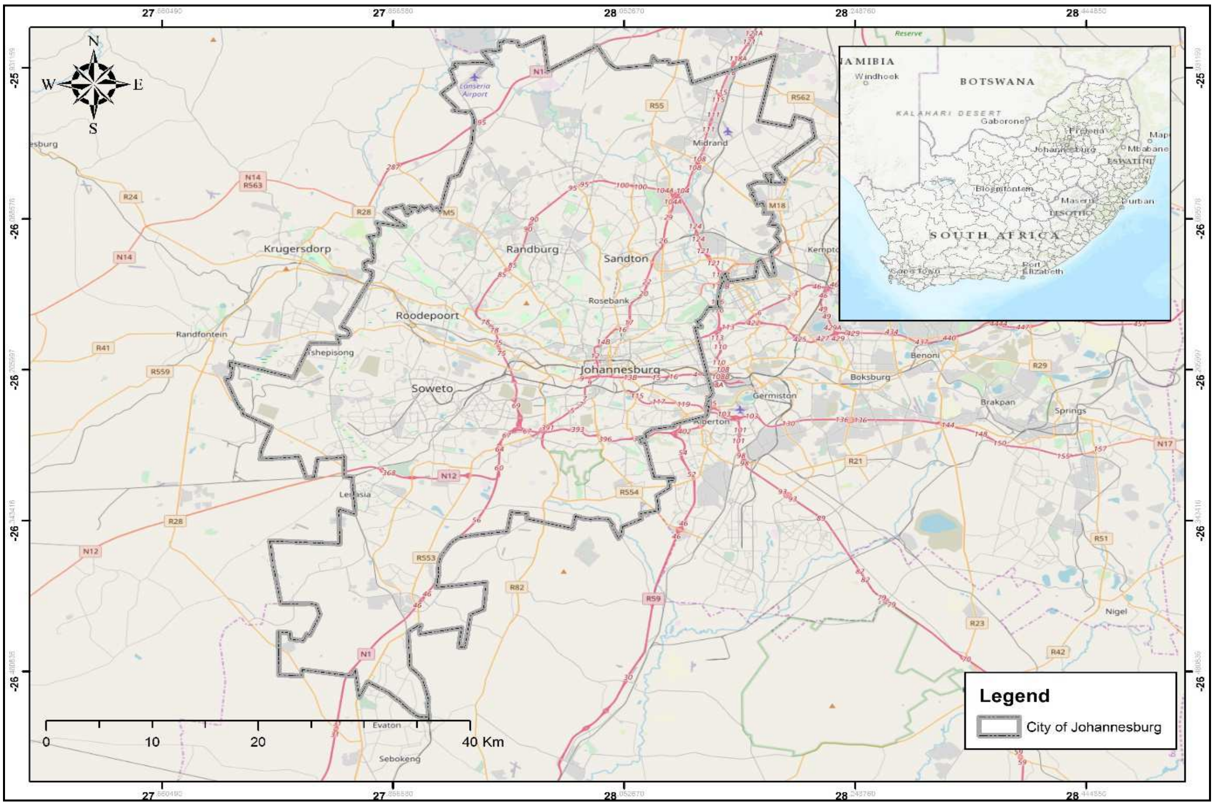

Figure 1: Study Area. Source: Author, 2021

5 METHODOLOGY

A mixed method research design was adopted where qualitative data and quantitative data analysis was used. Various research instruments were employed in the study. Five interviews were carried out with officials from different departments, including the Department of Transport and Metropolitan Municipalities transport planners whom assisted in providing insights for the study about the possibility of integrating the different public transport modes of formal and informal public transport in general, and how to integrate the different entities of UPTs in the city. Accordingly, commuters were also interviewed to understand how commuting is with and without information dissemination. 10 different daily commuters were interviewed who may have different experiences taking place daily. Purposive sampling was adopted as it was necessary to conduct interviews with informed officials and commuters. Interviews, observations and documented studies relating to this study were the sources of data. Further, content analysis was employed to review previous documented studies and used to for strategies to explain the methods of integrating both formal and informal public transportation. Secondary information used was obtained from larger data base such as Scopus, Science direct, Sage and Google scholar.

6 RESULTS AND ANLYSIS

6.1 Bus Rapid Transit System (Rea Vaya)

This mode of transport uses various forms of information dissemination for commuters which include plartform timetabling, online fixed timetables and public information display system in the stations and inside the bus.

The above figure shows a public information display system, these systems are not working in many Rea Vaya station. There are no clear indications on when the bus will be arriving at the stop and when it will depart from that station. Passenger of the Rea Vaya Transit complain that there is no specific time for travelling and buses stop and leave whenever. This is frustrating for workers who made 51% of the study group, this is because they are sometimes late for work due to the inconsistencies of the travel time. Consequently, on the stations where this system work's, the bus that does not arrive at the stipulated times.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Figure 2: Rea Vaya PID‘s [Source: Author, 2021]

6.2 Gautrain system

This mode of public transportation has trains and a buses, and it has most improved information dissemination in the city of Johannesburg as stipulated by commuters. There is availability of a mobile app that provide the operations of the Gautrain including the departure and arrival times, the movement of the train in real-time, how one can switch inbetween from Gaubus to Gautrain with reasonable time intervals allowing commuters for switch inbetweens. The stations have the PID’s in the station and inside the trains that functions very well.

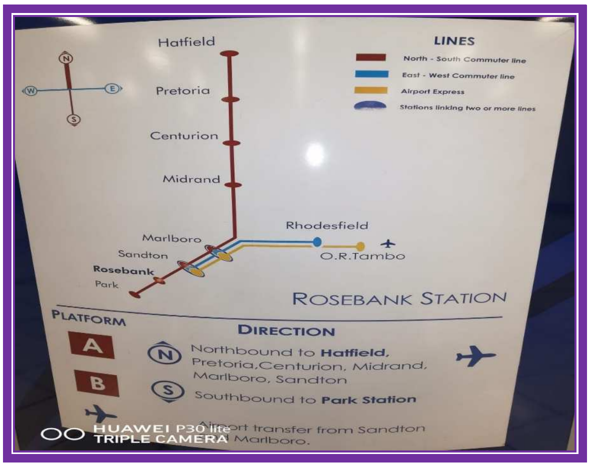

Figure 3: Gautrain map [Source: Author, 2021]

The above figure shows the Gautrain railways. These maps are placed at the entrance of everything station so that commuters know how the trains moves and how the stations are following each other. This also shows the directions of the railways, so that people who are going to the ORTIA can know where to get off and how they can change trains. Only 29% of the commuters were aware of this map, other commuters said they rely on the PIDs inside the trains that show which stop is next.

6.3 Public information display

In an age of mass public digital communication, large screen displays are emerging everywhere, particularly in well trafficked public places such as train stations, airports, hotels and shopping malls. These public displays have been receiving considerable attention as highly effective and visually compelling communications platforms, delivering information and related advertising (Lee, 2016). The figure below shows an example of a PID system and the information that is normally displayed for passengers.

Figure 4: PIDs [Source: Author 2021]

The survey revealed that 73,3% were aware of PIDs while 26,7% were not. It indicates that most respondents are aware that there are Public information Displays. Public Information Displays (PIDs) provide new possibilities for transportation companies to provide information at different stages of the journey. Public displays with interactive functionality provide the opportunity to support different users in their interaction, through specific support functions by providing information on schedule, calculate fares and train and bus routes. Gautrain has public information kiosk that offer users with the type of information they would need for their trip. These PIDs provide real-time and punctual information to commuters and 94% of the commuters were happy with these systems and the accuracy of the information.

6.4 Uber and taxify

This mode of transportation is convinient and reliable. It takes a certain number of people, it can be one to four if its a normal car, and if passengers are more than that they can be able to request for a large car that will be suitable for a group. It is expensive if is used by one individual compared to local minibus taxis and lesser if its used by a group as the prices are fixed based on the trip distance.

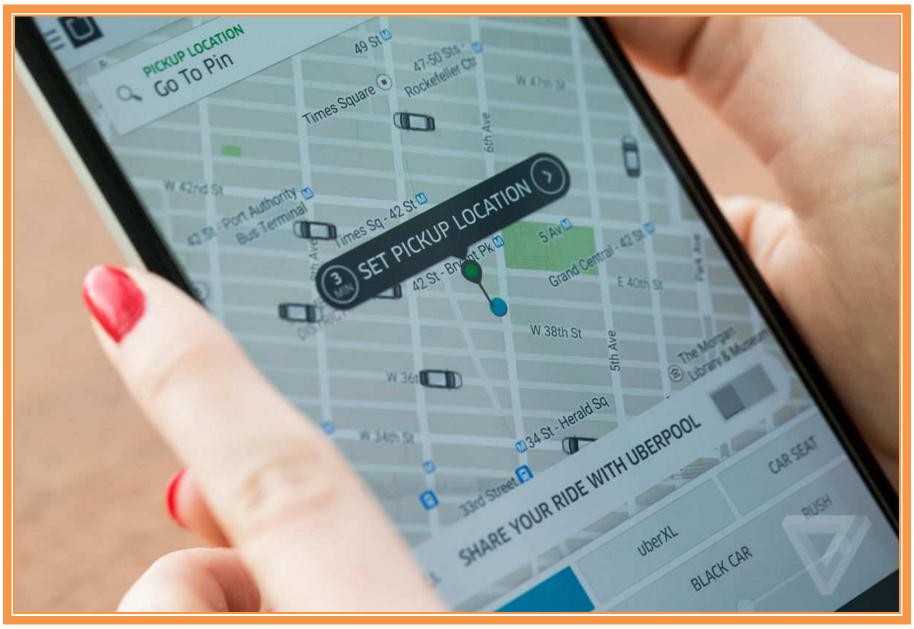

Figure 5: Uber App [Source: Author, 2021]

The above figure 5 indicates the application that is used for a uber/taxify for one to be able to request or use this mode of public transport. Many commuters deem this mode of public transport to be reliable as picks an individual at any convinient place from orig to destination without any unneccessary stops made. Commuters when requesting a ride can be able to see where the mode of transport is and the wait mostly is not more than five minutes if its a long time to wait. Further, the payment methods are done both electronically through the app and cash payment at the end of the journey.

5.5 Minibus Taxis

The operation of minibus taxis in the city of Johannesburg does not use any kind of technology to operate. Commuters commute in the designated taxi ranks (stations) and along the streets for conviniences. Areas differ from one location to the next depending on how the area is busy. The busy the area no more minibuses taxis are available and commuting is easy. In the locations that are not busy, it is hard for commuters to get minibus taxis.

Figure 6: Bree Taxi Rank [Source: Author, 2021]

The above figure indicates the one of the Johanessburg taxi ranks (minibus taxi station) where coummuters take the minibus taxis from origin to destination. Mostly, formal taxi ranks are designed in such manner and the only information that is provided are boards indicating where taxis travel to. There is no timetabling provided for commuters to know the times of taxis depature, on some occassions taxis take long to get to the rank and on some occassions they operate quickly. However, commuters use this mode of transportation without being aware of the timebling scheduling. Commuters use this mode mostly as it deliver commuters close to places of interest penatrating inside locations.

7 MOBILE APP IN REAL-TIME INFORMATION OF PUBLIC TRANSPORTATION

Previously, a passenger could, at best, come to know when a bus or a train left a certain station and when it reached another station. This was possible only due to human communication because someone recorded the time of arrival and departure at each station and conveyed this through a telephone system or a written report (Haris, et al., 2019). It was not possible to track the movement of the bus or train between successive stations. As a result, it was not possible to inform waiting passengers at a bus stop as to when their next bus was due. Commuters either depended on a pre-published schedule and hoped it was reliable, asked other waiting commuters, or just tried their luck. In contemporary urban public transport, it is possible not only to track the location of a bus or a train between stations' but it is also possible to know how fast it is moving and get a more precise estimation of when it would arrive. In fact, it is also possible to get a complete mapping of all public transport systems that a passenger proposes to use over a journey. The use of ICT has since become crucial to communicate real time information to commuters without guessing and relying on past experiences. Further, when one needed a taxi, the most common way of getting one was to get on to the street and flag one there. There was uncertainty on when one would arrive and, at odd hours of day, whether one would arrive at all.

The paper has indicated the modes of urban public transport that use ICT for information dissemination which indicated that this system provides information easy and commuters can be able to plan their daily trips and travelling becomes more simple even when switch inbetweens are neccessary. With the introduction of online application for minibus taxis can also make ridership simple for commuters wereby commuters book taxis online, or through an app, and track their movement until they arrive at the passenger’s doorstep. This saves the passenger from the stress of waiting endlessly, not knowing when a taxi would arrive.

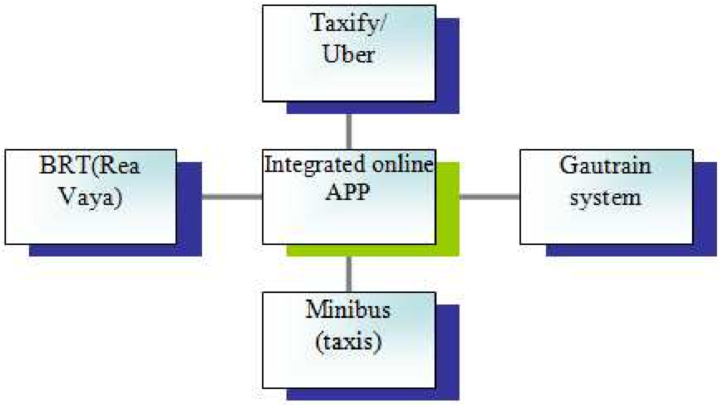

Figure 7: Integrated Information Dissemination for UPT [Source: Author, 2021]

The above figure 7 indicates an online information dissemination that can be used to integrate the different modes of public transportation that are mostly used in the city of Johannesburg. Commuters can login to an app indicating all these modes of public transport availability, real-time tracking and the fastest mode to reach the desired destination and allow commuters to make calculations for smooth switch in-betweens to create seamless travelling. The application could be used to book trips for any public transport mode and allow a commuter to connect trips switching from Gautrain system to uber/taxify or from Rea Vaya to a taxi. With such communication between these mostly used modes of public transport in the city, commuting would be much quicker and could attract more private vehicle owner to switch to public transport. Therefore, a positive change as this could reduce the traffic congestion challenge having roads that are mostly used by urban public tranport.

8 CONCLUSION

The world is making a rapid transition towards the fourth industrial revolution that is mainly characterized by technology and the internet. The latest technological innovations are rapidly and radically transforming the transport sector, creating the base for mobility solutions, which, accompanied to the cultural and socio-economic changes taking place all over the world, open the door to new future scenarios (Coppola and Silvestri, 2019). The use of Information and Communications Technology together with the Global Positioning System assists all stakeholders in urban public transportation to know the number of trips taken in a day for every vehicle and the time it used to travel. This in turn helps vehicle owners and operators with accountability and not being robbed by drivers. Commuters prefer multimodality as compared to only one option for public transportation. This helps the commuter utilize all available transport options to the current situation they find themselves in. This answers the questions of modern commuter’s choice since commuters can choose from a wide range of public transport systems and what can assist them to reach such decisions. Through the use technology, it is possible not only to track the location of a bus, taxi or a train between stations, but it is also possible to know how fast it is moving and get a more precise estimation of when it would arrive. In fact, it is also possible to get a complete mapping of all public transport systems that a passenger proposes to use over a journey. Sophisticated apps developed by many public transport operators allow a passenger to plan his or her journey across multiple modes, with an accurate estimation of the time it would take to complete the journey.

The demployment of technology is beneficial to contemporary urban public transport in that commuters avoid catching taxis on the streets by signalling their destinations, which has proven not to be safe. Taxis can be booked online which means reliable departure and arrival times. This will notify people in case of emergency in the traffic flow and assist commuters not to stress by not knowing when a taxi will arrive. Taxis can even be booked before they depart from the taxi rank, and the current systems for minibus taxis can stll be used for commuters who prefer the system of going to taxi ranks.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

9 RECOMMENDATIONS

The study has revealed the most used public transport modes in the City of Johanesburg which function differently and these modes of public transport they function from the early hours of the morning till late hours of the evening. Therefore, recommends an online information dissemination application for both formal and informal public transportation application that will inform commuters the real-time information whereabouts of the transportation modes, departure and arrivals time as to assist commuters to plan they trips properly. Further, assist commuters which mode is good for commuting at that particular moment indicating traffic congestions and delays, also assisting with the integration for seamless travelling on how commuters can switch inbetween different modes for smooth commuting with no delays.

1 ABSTRACT

Recently, there has been a high demand for urban sprawl because of rapidly increasing population. On the other hand, Building Regulations do not consider either human thermal comfort or energy consumption in the built environment. The quality of outdoor spaces in the built environment could be determined by many factors. This paper will investigate the impact and effect of three factors which are building orientation, relationship between building height and street width and microclimate conditions. This paper introduces a method to evaluate the efficiency of the outdoor built environment through the simulation process using Building Information Modelling (BIM) technology. This research aims to solve the problems of thermal comfort and energy consumption in the built environment. These problems were mainly the result of building codes that were not sensitive to the built environment as the codes focus on the buildings themselves. The case study is located in downtown Alexandria city, Egypt. Its area is approximately one square kilometre. This research supports urban planners and designers in making decisions before implementation to reach thermal comfort in the built environment. It contributes to revealing the importance of factors affecting the outdoor built environment and taking them into consideration while establishing new codes or amending existing building regulations.

Keywords: Built Environment – Building Regulation – Building Codes - Thermal Comfort – Energy Efficiency – BIM.

2 INTRODUCTION

Of all the design fields, urban design has the greatest impact on the nature of cities and city life. No matter How logically the land-use pattern is prescribed by city planners, the beauty and utility of its buildings and the nature of the landscape, it is the overall combination of forms and spaces as seen in time and over time that gives a city its character. City planning has broadened its scope of concern in an attempt to be comprehensive in its outlook. Landscape architecture has considerably extended its domain of interest from a horticulture base to include urban environments, while architecture has many practitioners who focus on different aspects of the built environment. Architecture has contracted its scope of concern spinning off sub-fields as new environmental problems have arisen. One of the current generation's challenge is to understand the broad impact of our built environment on thermal comfort better. Building regulations may be the only comprehensive ones that can contain all factors to achieve a better built environment and healthy cities in the future and improve the existing built environment.

Building Information Modeling (BIM) It is to provide users with the ability to integrate, analyze, simulate and visualize the geometric or non-geometric information of a facility. One of the most significant characteristics of BIM is that it can provide the required information in an organized pattern.

3 BUILT ENVIRONMENT

The term 'built environment' refers to aspects of our surroundings that are built by humans, that is, distinguished from the natural environment. It includes not only buildings, but the humanmade spaces between buildings, such as parks, and the infrastructure that supports human activity (Committee on Physical Activity 2005). The Centre for Digital Built Britain defines the built environment as; 'All forms of buildings (residential, industrial, commercial, hospitals, schools), (Lang, 2005). Broadly defined, the built environment includes the buildings and spaces we create or modify (Karen and Oleru 2008)(McClure and Bartuska 2007). The built environment is a material, spatial and cultural product of human labour that combines physical elements and energy in forms for living, working and playing (WIKI 2012) (Blog 2015) (Matt 2015). In recent years, public health research has expanded the definition of "built environment" to include healthy food access, community gardens, “walkability", and “Bick ability” (built environment 2021).

Well-being in the built environment is a topic that features frequently. However, despite this surge in attention, there are still many questions on how to nurture, measure, and design for well-being in the built environment effectively (Luo, et al. 2018). Physical and physiological well-being depends on current states as well as on previous history of exposures, while anticipation of future events can drive neural mechanisms and psychological balance. For example, solar ingress in built spaces might be favoured, particularly in a cold climate or season, to bring passive heating and decrease lighting energy use (Mangone, Kurvers and Luscuere 2014). However, bright sunlight could cause glare and reduce visual task performance. Yet, direct exposure to natural light particularly in the morning (Baron 1990) (Mangone, et al., 2014) is beneficial.

The building industry appears to be entering another period of change in essence of minimising energy, carbon and environmental footprints of various building types (Owusu and Asumadu 2016). Globally, energy demand of buildings amounts to one third of world energy use. This change is being driven by a need to optimise and conserve resources, especially energy (Freedman 2015). The architects as important stakeholder has important roles to play in accomplishing this onerous goal (GANIYU and ADETUNJI 2015) (Newton, et al. 2012) (Pickles 2011) (Lehmann, 2011; Shanghai Manual, 2011) (Janda, 2009) (Toledo, 2006).

4 BUILDING REGULATIONS

Regulations are designed to protect buildings and the people and property inside them from any extreme events. They also ensure system safety, as well as accessibility and practical and achievable levels of energy efficiency (Francis & Steven, 2018). Building codes underpin the work of architects, engineers, builders and developers (USAID, 2013).

The existence of building regulations goes back almost 4,000 years. The Babylonian Code of Hammurabi. The protection of the health, safety, and welfare of the public is the basis for licensure of design professionals and the reason that building regulations exist. (Francis & Steven, 2018). The beginning of modern codes can be traced to the 1897 publication of the NFPA’s National Electrical Code. Early attempts to prevent fires, predecessors of today’s zoning laws and safety codes included requirements for wider streets, limitations on building spacing and height, and elimination of thatched roofs and wooden chimneys in cities. Sanitation concerns were the moving force behind some early codes and over the years, have led to plumbing standards, lighting and ventilation requirements, minimum room dimensions and other health and safety requirements we take for granted in today’s building codes (Report: The Value and Impact of Building Codes 2013) (Ching 2016) (Bank 2015) (Jawaida, Pipraliab, & Kumarb, 2018).

5 BIM INTEGRATION

The concept of building information model BIM was coined by Charles M. Eastman at Georgia Tech (Eastman, et al., 2008) and from 1970s he has worked on an extension of the BIM. His main research focuses on product modelling, data modelling and information modelling in engineering (Eastman, 1994) (Sacks, et al., 2010). The concept of BIM means building a building virtually prior to building it physically, in order to work out problems, and simulate and analyse potential impacts (Morlhon, et al., 2014). BIM can be used as a tool for generating and managing data during the life cycle of structures. BIM covers building geometry, spatial relationships, geographic information, and quantities and properties of building components (Namlı, et al., 2019) (Salman, et al., 2012) (Lee, et al., 2006) (Kymmell, 2008).

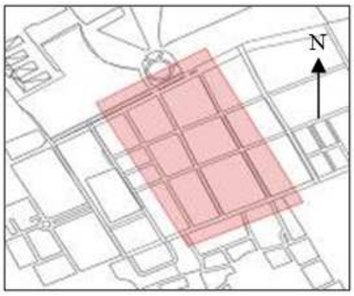

Fig. 1: Selected Block to be studied

Recently, BIM, has been able to digitise a great amount of building information and that is why it has received much attention in the field of construction project management (Wang, et al., 2014). Applying BIM in delivering construction projects has been on the rise (Guo & Feng, 2019) (Oraee, et al., 2019).

Meadati (2007) expresses that BIM is only used at an early stage and tries to integrate BIM by the 3D as-built model to increase the capability of BIM during the maintenance period. In terms of automation in BIM, several scholars have worked on this area, and accuracy and reliability of the model were their main concerns (Meadati, 2007).

6 CASE STUDY

6.1 Description

The case study is located in downtown Alexandria city, Egypt. Its area is approximately one square kilometre. A block bounded by 3 streets in two perpendicular directions will be studied as shown in figure 1.

6.2 Methodology

An analytical comparison of two cases using BIM simulations and software aimed to find solutions to the current situation and achieve better results in the future. Autodesk Revit was used to create a 3D model of the case study as shown in fig.4, B and to produce shadows results. DesignBuilder software was used to run a full simulation process on both cases as shown in fig 4, A&C. The following are the steps followed for both cases before the debate process, and the determinants change for each case.

(1) Surveying and noting the study area, building height and street widths as shown in figure 2.

Fig. 2: Fouad street live shots

(2) Drawing a site map on the Architectural Revit program using BIM technology as shown in figure3.

Fig. 3: The development of work on building the case study. Left: autocad site map, Middle: Google site map, Right: Revit 3d model as masses

(3) Determine the parameters and build the three-dimensional model of the case study based on the difference between the relationships between the width of the street and the height of the buildings and the determination of setbacks.

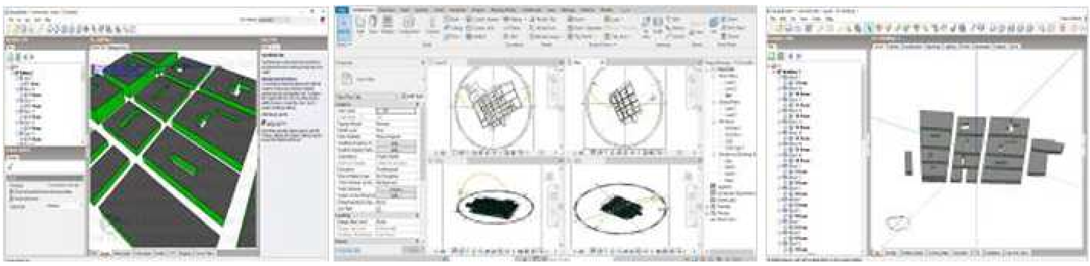

Fig. 4: Screen Shots While building 3d model and run simulation. Left: DesignBuilder Simulation, Middle: Autodesk Revit, Right: BesignBuilder model

(4) Definitions and Abbreviations of parameters used to determine and limit the case study simulation cases are: H = Hight of the building, W = Street width, X = Setback Value from property line

6.3 Solar and Energy Study

Each case will study the sun moving from sunrise to sunset by using BIM simulation and its effect on building façades and thermal comfort in the built environment.

The simulation was conducted in the summer and winter seasons, and the results were extracted for the two days representing each season. June 21st is the representative day of the summer. December 21st is the representative day of the winter. The effect of the movement of the sun, shade and shadows was observed in areas of the street and also on the facades of the buildings at three times of the day, which were eight in the morning, twelve noon, and five and four in the afternoons in summer and winter respectively.

6.4 Case I (Explore, Parameter's Equations & Simulation study)

The first case represents the current situation that has been established in the implementation of Egyptian Building Law No. 119 of 2008. The determining factors for the first case are only the relationships between street width and building height. As the executive regulations of the Building Law stipulates, the height of the building must be equal to 1.5 the width of the street.

H = 1.5 x W X = 0

These equations mean that the height of the buildings is equal to one and a half times the width of the street, without any setbacks from the property line, with regard to construction on the whole plot of the land area, but with the presence of internal skylights that differ between residential and service.

6.4.1 Study Simulation in summer

The simulation results in summer show first a site plan view to illustrate areas of shade and shadows on street level and then in a perspective view with coloured façades that represent the temperature on each façade.

Fig. 5: Site plan Shade and Shadow in summer. Left: 8 o'clock, Middle: 12 o'clock, Right: 17 o'clock

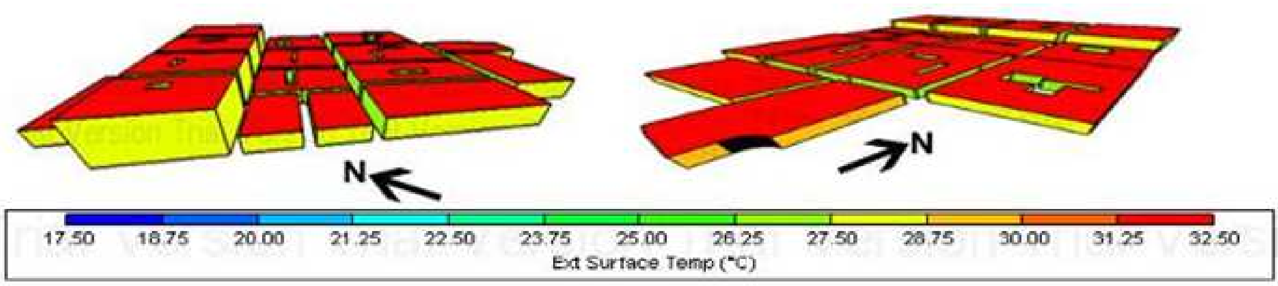

Fig. 6: Exterior surface temperature (°C) in summer. Left: Show South, West façades, ight: Show North, East façades

6.4.2 Study Simulation in Winter

The simulation results in winter show a site plan view and a perspective view which illustrate the difference between the degree of inclination of the sun.

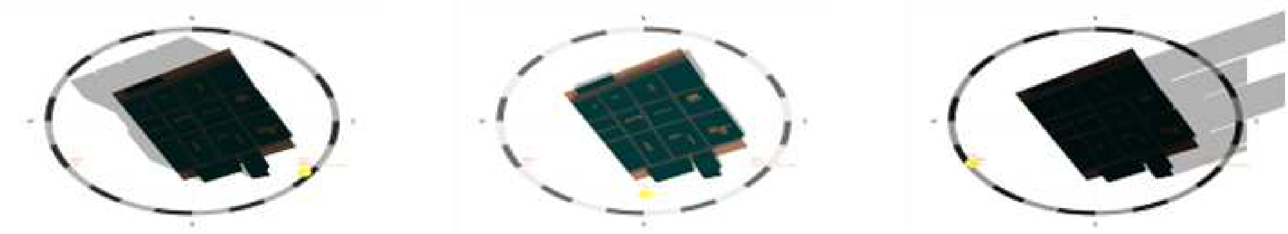

Fig. 8: Site plan Shade and Shadow in winter. Left: 8 o'clock, Middle: 12 o'clock, Right: 16 o'clock

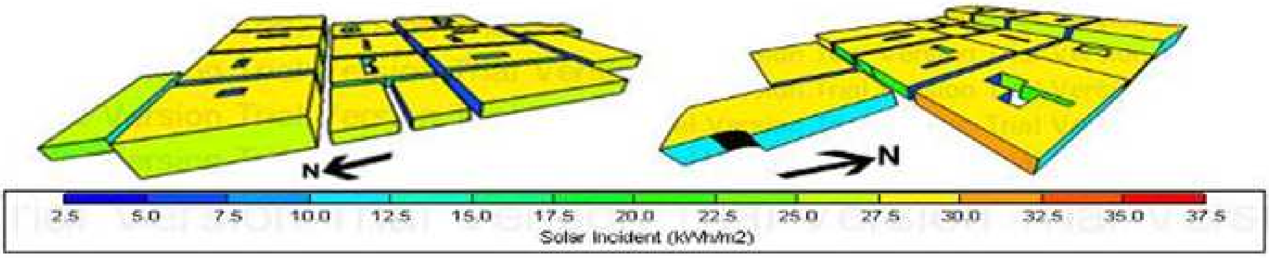

Fig. 10: Solar Incident (Kw/m2) in Winter. Left: Show South, West façades, Right: Show North, East façades

6.5 Case II (Explore, Parameter's Equations & Simulation study)

The second case represents the proposed case for amending the Building Regulation, taking into account the orientation for buildings and the voids related to this orientation. The factors affecting the second case are not limited to building height and street width, but extend to orientation, setbacks.

H = W X = 2.5

These equations mean that the height of the buildings is equal to the width of the street. There is a setback from the property line of two and a half meters, which means that building on a part of the area of the land lot, while maintaining the presence of an internal light-well.

6.5.1 Study Simulation in summer

The simulation results in summer show a site plan view to illustrate areas of shade and shadows on street level and then on a perspective view with coloured façades that represent the temperature on each façade.

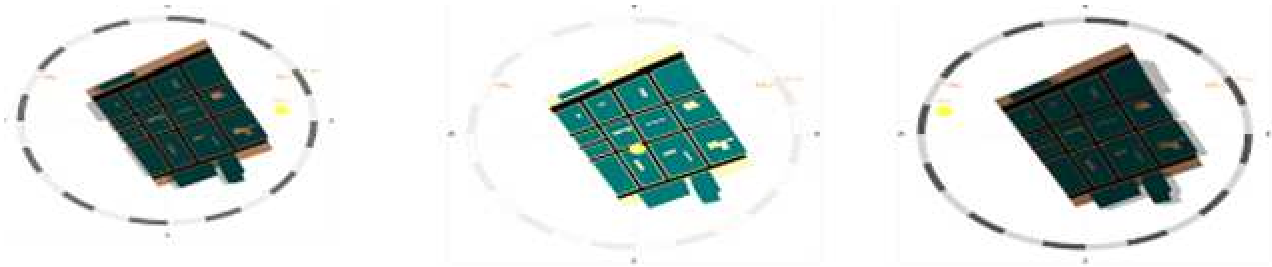

Fig. 11: Site plan Shade and Shadow in summer. Left: 8 o'clock, Middle: 12 o'clock, Right: 17 o'clock

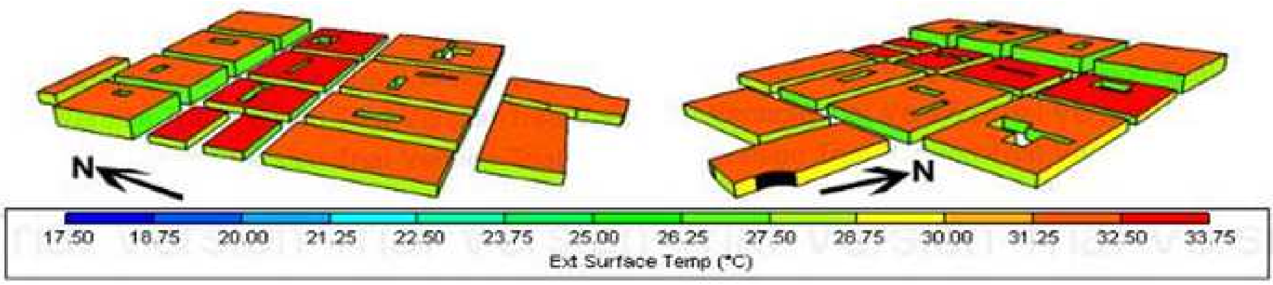

Fig. 12: Exterior surface temperature (°C) in summer. Left: Show South, West façades, Right: Show North, East façades

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

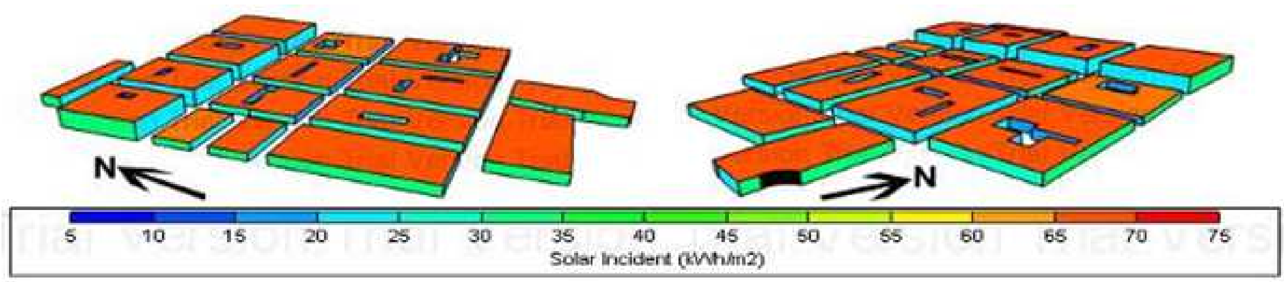

Fig.13: Solar Incident (KWh/m2) in Summer. Left: Show South, West façades, Right: Show North, East façades

6.5.2 Study Simulation in Winter

The simulation results in winter show a site plan view and a perspective view which illustrate the difference between the degree of inclination of the sun.

Fig.14: Site plan Shade and Shadow in winter. Left: 8 o'clock, Middle: 12 o'clock, Right: 16 o'clock

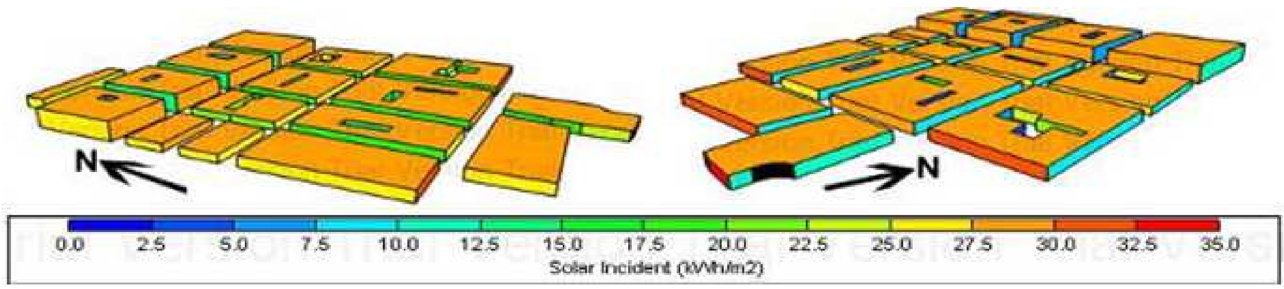

Fig.16: Solar Incident (KW/m2) in winter. Left: Show South, West façades, Right: Show North, East façades

6.6 Results

By comparing the results between the two cases, we will find that changing the equations affecting the height relationship with the width of the street beside setback value that are corresponding with the building volume, affected the shade and shadow areas, the exterior surface temperatures of roofs and façades with different orientations, as well as the amount of solar incident.

7 DISCUSSION

In the summer it is best to have more shaded areas as protection from the sun and to cool down the atmosphere in streets and inside buildings. It is desirable to decrease temperatures of the roofs and façades and thus the need for energy consumption in cooling or HVAC systems will decrease accordingly. Also, this gives designers an opportunity to use responsible and local building materials.

By looking at the results shown in Table 1, it is noticed that in Case II, the temperature to which the roofs are exposed decreased by two degrees Celsius, while on the southern façade it decreased by 3 degrees Celsius. On the other hand, the eastern façade was not significantly affected, in contrast to the western façade, which decreased by more than 4 degrees Celsius.

As for the winter season, the best situation in it differs like in the summer because we are looking for warmth and we contribute to increasing the temperatures exposed to the façades and surfaces in order to reduce the need to operate artificial heaters that consume large quantities of energy and harm the personal health and the built environment. Also, intend to have higher temperatures in spaces inside and outside buildings would affect production process as it will be more comfortable for human beings to work and produce effectively.

	Case I	Case II
Summer Condition		
Shade and Shadow	Small as shown in fig. 5	Wide as shown in fig. 11
Exterior surface temperature values for each façade (°C) as shown in fig. 6&12		
Roofs	(31 - 33) °C	(29 – 31) °C
South	(25 - 28) °C	(23 - 25) °C
West	(27 - 29) °C	(22.5 – 26.5) °C
East	(25 - 27) °C	(25 - 27) °C
Solar Incident Values for each façade (KWh/m^2) as shown in fig. 7&13		
Roofs	(65 – 75) KWh/m^2	(60 -70) KWh/m^2
South	(25 - 35) KWh/m^2	(15 - 30) KWh/m^2
West	(40 - 50) KWh/m^2	(30 - 45) KWh/m^2
East	(30 - 40) KWh/m^2	(20 -35) KWh/m^2
Winter Condition		
Shade and Shadow	Spread as shown in fig. 8	Shrunk as shown in fig.14
Exterior surface temperature values for each façade (°C) as shown in fig. 9&15		
Roofs	(15 - 16) °C	(17 – 18.5) °C
South	(18 – 19.5) °C	(18.5 – 20.5) °C
West	(16.5 - 18) °C	(17.5 - 19) °C
East	(14.5 - 16) °C	(16 - 17) °C
Solar Incident Values for each façade (KWh/m2) as shown in fig. 10&16		
Roofs	(25 - 30) KWh/m^2	(27.5 - 30) KWh/m^2
South	(17.5 - 25) KWh/m^2	(22.5 - 35) KWh/m^2
West	(15 – 22.5) KWh/m^2	(17.5 - 25) KWh/m^2
East	(7.5 – 17.5) KWh/m^2	(10 - 15) KWh/m^2

Table 1: Results: comparison for both cases I & II

By observing the results shown in Table 1, we will find that Case II is better in terms of the temperatures exposed to surfaces and facades which are higher than in Case I. For example, the southern façades in Case II are a degree and a half higher than that of Case I. The surfaces have increased temperatures by two degrees Celsius. The façades of the eastern and western buildings rose by one degree.

8 CONCLUSION

Building Regulations affect the built environment directly. Thermal comfort in the built environment which means in streets and the surrounding buildings cannot stand alone without considering interior thermal comfort in buildings. Building regulations should also give more concern to the outside of buildings as well as organising and considering the building itself. Architects, designers, constructors and stakeholders must be aware of new techniques that appear in this field and know how to use them, benefit from them and upgrade them to contribute to improving human well-being. The use of Building Information Modelling technology is increasing and it is the upcoming future.

Integrating User Needs in Sustainable Neighbourhood Transition of the Smart City – Expanding Knowledge and Insight among Professional Stakeholders

Daniela Baer, Anandasivakumar Ekambaram

(Daniela Baer, Research Scientist, SINTEF Community, 7491 Trondheim, daniela.baer@sintef.no)
(Anandasivakumar Ekambaram, SINTEF Community, 7491 Trondheim, siva@sintef.no)

1 ABSTRACT

Climate neutral and social inclusive cities are set high on the European Agenda. The smart city approach is considered to be one measure within socio-technical systems to reach this ambition. In recent years, smart city initiatives were criticised for having fallen short of their objectives to meet user needs and public value creation (Hollands, 2008; Cardullo et al., 2019). Besides accelerating citizen participation activities, we assume that capacity building among professional stakeholders with the help of (social) learning can contribute to the development of more citizen-centred solutions in the built environment. Especially when resources or citizens availabilities are limited, capacity building among professional stakeholders can be an important contribution to get a better understanding and insight of public value creation in the built environment.

In elaboration of this assumption, we set the spotlight on Zero Emission Neighbourhoods (ZEN) as one smart city approach to reach more climate neutral cities through an integrative approach to transform socio-technological systems. We ask how citizen needs could be better integrated in the development of smart city projects within the built environment. In particular, we investigate how professional stakeholders, such as developers, landowners, planners, civil servants can gain more insight and knowledge of citizen needs and values to create solutions that are in line with their demands and thereby foster public value creation in a better way. Building on theoretical concepts for innovation and learning and findings from a case analysis of a Norwegian neighbourhood in transition, we present a concept for a workshop as a tool to detect market preferences through insight in citizen needs. We thereby contribute to elaborate on learning within multi-stakeholder settings and especially capacity building among professional stakeholders. Additionally, we provide practical guidance for using a tool that can be seen as a contribution to approaches towards stakeholder participation as well as for a methodology of local context-based tools for social learning.

Keywords: Zero Emission Neighbourhoods, Social innovation, Sustainable Transition, Multi stakeholder partnerships, User needs

2 INTRODUCTION

2.1 Climate neutrality in the build environment through the development of zero emission neighbourhoods

Developing the built environment of the future that is climate-neutral and at the same time socially inclusive is a major challenge for all actors involved – especially since the challenge is wicked, and situated between different sectors and actors. The aim is to find appropriate solutions within a holistic approach in collaboration between those involved and in all phases of development from the planning, construction and operation phase of the built environment.

The co-creation of solutions becomes even more important when ambitions for neighbourhood development are higher than existing laws and regulations are asking for. Reaching climate neutrality in the built environment is such a vision. Agreed during the UN climate mission in Paris, the participating countries have agreed to lower their carbon footprint towards zero until 2050. While translating these goals into national and municipal policies, some countries, regional or municipalities set their ambition even higher to become carbon neutral in a shorter timeframe. A special focus lies here on the built environment since it is one of the main sources of greenhouse gas emissions and on the energy sector that is to be transformed to renewable energy (Global Alliance for Buildings and Construction, 2019). Additionally, the neighbourhood gets more and more attention as it is identified as a main area to enable change and to realise diverse cross sectoral cutting effects and scale effects (Jank, 2017).

One integrative approach to reach for climate neutrality in the built environment is the concept of Zero Emission Neighbourhoods developed by the Research Centre for Zero Emission Neighbourhoods in Smart

Cities (ZEN Centre). A zero emission neighbourhood aims to reduce its direct and indirect greenhouse gas (GHG) emissions towards zero over its life time. With the help of life cycle assessment in all phases of neighbourhood development – including, planning, implementation and operation – the total number of emissions is assessed. These emissions are compensated through renewable energy production on site during the operation phase of the neighbourhood. The ZEN centre has developed key performance indicators (KPIs) within seven categories: GHG, energy, power, mobility, economy, spatial qualities and innovation, both to assess the status towards carbon neutrality and to help stakeholders to guide them to identify the right solutions (Wiik et al., 2019).

2.2 Co-creation and stakeholder's role in sustainable transition

An open dialogue and interaction of stakeholders involved in zero emission neighbourhood development, will facilitate co-creation of new solutions and innovation, which are needed to meet the challenges of the future and to achieve the sustainability goals that countries, cities and municipalities have committed themselves to. These challenges of the future need to be answered with tools and knowledge from a majority of actors (Schneidewind et al., 2016; Soma et al, 2018).

Nielsen et al. (2019) argue that the often very technical-oriented ambitions of smart city projects in the built environment have led to narrow dialogues which undermine the real power and capacity of stakeholders, including citizens to influence urban-planning outcomes. Fiskaa (2005) believes that neoliberalism in general has strengthened the position of landowners, business interests, and developers, in urban development. The politically driven neoliberal trend in our study country Norway has also given private entrepreneurs a prominent and driving role in urban development, that can create dependency on markets (Falleth et al., 2010).

Simultaneously, economically markets of the built environment are dependent on demand and interest of potential buyers. Smart city projects with high environmental ambitions and technological solutions do challenge stakeholders with the novelty of their concepts and technological solutions. ZEN neighbourhood developments are challenged by uncertainty and perceived risk – both from the stand-point of the citizen as end-users of buildings and infrastructure and of professional stakeholders as developers or land owners.

One approach to obtain a better insight in market preferences and citizen demands is direct participation to develop solutions for neighbourhoods that are in line with citizen demands. At the same time, the facilitation of participation processes is depending on the goal of participation, the degree of appropriate engagement, the stage of the project at which participation occurs, the capacity of stakeholders and the resources available (Raynor et al., 2018). Participation is embedded in a local context and its implementation depends on different factors. An additional approach is capacity building of professional stakeholders to develop deeper insight and understanding in citizens' needs and demands which will enable them to provide solutions closer to citizen needs.

2.3 Outline

This paper looks at how professional stakeholders, such as developers, landowners, planners, civil servants can gain more insight and knowledge of user needs and values to create solutions within neighbourhood developments that are in line with user needs and thereby foster public value creation.

Following the introduction, the paper provides a brief description of relevant theories and concepts in section 3 while section 4 is about the methodology that was adopted in this study. The results of the case study are presented in section 5 which describes the case study of a neighbourhood development in Ydalir, Norway and hence provides the context and need for a tool for capacity building and identification of marked preferences. Based on this analysis, the concept for the tool is developed and presented. Section 6 focuses on analysis and discussion. The concluding section 7 winds up the whole discussion.

3 LEARNING FOR SUSTAINABILITY - RELEVANT THEORIES AND CONCEPTS

In this section, we present relevant theories and concepts that help us to study how professional stakeholders obtain insight and knowledge on user needs and values. In this regard, we look at the following concepts: social innovation, social learning, capacity building, design thinking, and single- and double-loop learning. These concepts are mutually related and overlapping, at least to a certain extent. At the end of this section, we present a figure to illustrate how these concepts are inter-connected.

Social innovations are widely understood as new ideas that aim at meeting social goals (Hellström, 2004). Therefore, the role of social innovations within the development of socio-technological systems as highly ambitious neighbourhoods is to enable improvement of the well-being of citizens and the civil society in general. The involvement of citizens and stakeholders is one crucial element to enable social innovation within the quadruple-helix model (Carayannis et al., 2009), a model of cooperation among stakeholders from the public and private sectors and academia, with a strong emphasis on citizens and their needs. Social innovation within the Nordic model relates to activities that are social and representing both needs and ends, such as collaborations between multiple stakeholders in the community that initiate and drive developments to meet new challenges of the future (Copus, 2017).

Social innovation can be understood as output of social learning processes, which do occur in heterogenous setting of stakeholders with diverse values and conceptional frames, knowledge, interests, and resources (Beers et al., 2016). When these stakeholders share their knowledge in an interactive process – often generated in a workshop setting facilitated by a neutral person – they are likely to produce new knowledge and trust, and this lays the basis for joint action (Pahl-Wostl, 2006). Social learning emphasises the output of learning processes, which, besides joint action, can also result in new skills and capacities. Capacity building is defined as activities that strengthen the abilities, knowledge, skills and behaviour of individuals (individual capacity building) or organisations (organisational capacity building) (Ku et al, 2013; Farazmand, 2004). Capacity building is thereby understood as both a process for improving the capacities of individuals and, at the same time, as an outcome of that process (Jensen, 2017). In relation to citizen participation, capacity building is understood as either local government institutions aiming to enable citizens to participate or to build up human capital in the form of skills, experiences, and knowledge (Pretty, 1999; Jackson, 2001).

Design thinking as a process, is a user-centred approach to address wicked problems through collaborative problem-solving and ideation of diverse stakeholders (Brown and Wyatt 2010). Through an iterative process and a set of different methodologies, participants are designing products or services in this process that improve user experience and enhance public value (Mintrom, Luetjens, 2016). Enabling to understand the perspective of others, design thinking facilitates greater empathy and entails understanding different perspectives, cultures and contexts that will inspire a holistic solution. Design thinking can thereby help to promote and design solutions and systems that are more responsive to citizen needs (Raynor et al., 2018). Design thinking consists of four key characteristics. These are: (1) placing humans and their needs at the heart of the enquiry; (2) embracing optimism, openness, non-linearity, complexity, ambiguity and uncertainty; (3) adopting fast iterative and experimental processes through a variety of design methods and hands-on tools, and (4) using tangible, accessible and collaborative methods of communication to share with stakeholders throughout the project's development (Raynor et al., 2018).

Within social learning setting, the concept of single and double loop learning, which was originally drafted within organisational learning, focuses also on the ability to change existing values and conceptional frames and thereby also open up more radical innovations. Argyris and Schön (1996), who developed this concept, discuss about learning as understanding and eliminating the gap between the expected result and the actual result of an action. The gap between the expected results and actual results can be eliminated by either making changes or taking corrective measures within the existing values and norms (by changing strategies of action or underlying assumptions of the strategies that are within the values and norms) – that is, single-loop learning, or by changing the existing values and norms – that is, double-loop learning. While the single-loop learning focuses on doing things right within the realm of the existing norms and values, double-loop learning focuses on doing things right according to the nature of the circumstances and changing conditions and thereby enabling for more open and integrative innovation processes. Connection between the relevant concepts that we have presented above can be seen in several ways. One of the ways to look at the connection is illustrated in the following figure:

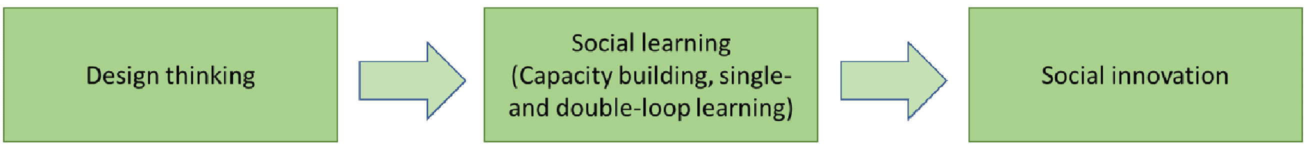

Fig. 1: Connection between the relevant concepts on innovation and learning

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

As Figure 1 shows that design thinking can be seen as an overall approach that could guide to develop and conduct learning and capacity building processes, which in turn could lead to social innovation. This linear connection of the concepts functions as a kind of a theoretical framework for this paper.

4 METHODOLOGY

Our methodological approach is threefold: Firstly, we studied literature on concept and theories for learning in sustainable transition to develop our methodological framework for this study. Secondly, we conducted a case study for the neighbourhood of Ydalir in Elverum (Norway), aligned with 8 qualitative interviews with involved stakeholders, to identify challenges as well as needs and knowledge demands towards markets preferences. Ydalir is a demonstration site within the ZEN Centre. Thirdly, based on the results of the first two steps we developed a tool for capacity building among professional stakeholders to enable them to come up with social innovation in sustainable neighbourhood development and transition.

5 RESULTS OF THE CASE STUDY

5.1 Background information

The neighbourhood of Ydalir is a new development on a former sand quarry, located in the mid-size town Elverum in County Hedmark in Norway. It has a size of approx. 330 000 m2, and it is located 1.5 km from the town centre. The estimated timeframe for completion is 2035 and 800 to 1 000 residential units are planned (approx. 100,000 m2). The residential units are planned as a combination of detached houses and apartment buildings, and will be built around a school and a kindergarten, which were completed and opened in autumn 2019.

The main stakeholder is the project owner Elverum Vekst. Elverum Vekst (EV) is fully owned by Elverum municipality and aims to promote growth in both population and businesses. Operational activities related to area development and sale of plots are carried out through the subsidiary land development agency Elverum Tomteselskap (ETS). At the beginning of the development in 2015, 80% of the land in Ydalir was owned by the land development agency. Since then, two plots were already sold to local housing developers. Two private landowners count for the remaining 20% of the area. Other stakeholders involved are Elverum municipality, several local private developers who have signed intention agreements with ETS, consultant agencies, the local transportation agency, the local energy utility company that will deliver district heating and grid connection, and the local waste management company.

From 2016 to 2018, a masterplan for Ydalir was developed in a collaborative process facilitated by the project owner. Five workshops over a period of six months were dedicated to different aspects of the project development. These included topics such as aims and vision, energy, building and infrastructure, user and quality aspects, and transportation. The project owner, ETS, invited deliberately a wider group of participants to the five workshops, in order to integrate as many stakeholders as possible in the masterplan development and create knowledge and commitment for further development. The result of this process is the masterplan, which aims to ensure the realisation of basic qualities within the areas of urban design, energy and material use, blue green infrastructures and waste management, while also being flexible enough to accommodate individual solutions provided by the developer. The ambition for Ydalir is to become a zero emission neighbourhood. To reach this ambition, the masterplan consists of measures to follow in different areas, from local energy production to use of material with low embodied emissions, and measures to reduce mobility demand and strengthening the design of attractive public spaces.

At the beginning of the planning phase, a branding strategy was developed for Ydalir in 2016 to address potential buyers. A workshop was conducted with participants from ETS, local politicians, members of the administration of the municipality, and representatives for the focused inhabitant groups of Ydalir (families and young persons). The aim was to identify needs and values of the potential inhabitants regarding the neighbourhood development. Representatives from different potential user groups participated in the workshop: citizens who have just moved to Elverum, former citizens of Elverum who are living out of town and are considering moving back, as well as older residents living in Elverum.

5.2 Actual situation and need for deeper insight in market preferences

Stakeholders involved in Ydalir had expressed in former studies lack of knowledge in different thematic areas and a need for knowledge development and capacity building in them. Areas that were pointed out are knowledge on implementation of building solutions that go beyond existing building standard TEK 17, holistic and integrative project management for the whole neighbourhood development, system definition and geographical size of the ZEN neighbourhood (Baer, 2018). Uncertainty about the demand for residential units in Ydalir was already expressed at the beginning of the project in 2017, due to the stagnating population development in the city of Elverum. This perceived risk got more attention in a later phase of development, when the first developers begun to regulate their sites and started to sell the plots to future inhabitants of Ydalir. Initially, the landowners and developers considered the limited parking spaces per unit in line with high environmental ambitions as a challenge to sell the plots. Due to the influence of housing developers and landowners, the masterplan of Ydalir was reviewed and the parking regulations were watered down so that the number of parking spaces per unit was increased in 2019. The professional stakeholders expressed their interest and need to intensify joint marketing activities and develop better insight in market preferences and knowledge on "what sells" to include in the narrative of the marketing content for a ZEN area.

In September 2020, the land development agency initiated a first meeting with the developers who had bought properties in Ydalir or signed intention agreements to get feedback on the idea of joint marketing activities. The meeting was hold in the school of Ydalir, one of the first buildings in Ydalir, which was built to share rooms and facilities with the neighbourhood and to function as a neighbourhood centre. Professional stakeholders showed interest in gaining deeper insight in the content of marketing activities of ZEN areas and to intensify collaboration on joint marketing activities.

Citizen participation was mainly facilitated by following the plan and buildings law for public consultation of respective planning documents. From the project owner's and the developer's sides, citizens are mainly addressed as consumers, buyers and potential clients. Direct involvement in form of participation of representatives for potential client groups took place at a workshop for the branding strategy of Ydalir in 2017. Stakeholders involved describe the process so far as a confined culture for direct citizen participation.

To sum up, the professional stakeholders, mainly developers and land owners, perceived the risk that the development of a ZEN neighbourhood following higher environmental regulations was not in line with market preferences. Furthermore, there was perceived uncertainty among these groups about what a ZEN neighbourhood offers the market and why it is attractive for citizens to buy a house in Ydalir. The capacities and resources available in the demonstration site were geared towards building on the expressed need to get deeper insights in market preferences and appropriate marketing approaches of a ZEN area. At the stage when the project development of Ydalir was on the tipping point between the planning and the design phase and the first buildings were completed, stakeholders involved expressed a need for an "easy to handle" approach/tool to elaborate marketing activities. The goal of this tool was to cope with perceived risk and uncertainty through capacity building and deeper insight in market preferences and needs and how ZEN solutions could satisfy them.

5.3 Concept for a market preference tool

Building on the literature review of diverse approaches towards learning and knowledge development in transforming the built environment into a more sustainable one, as well as on the need analysis of the case study of Ydalir, we drew up a concept for a workshop design that focused on working with market preferences. We call it the Market Preference Tool (MPT), presented in figure 2.

The Market Preference Tool's main element is a workshop, which is aligned with a preparation and follow-up phase. We present the tool and the learning concept of the workshop in a chronological order. After a short introduction of the tool in its specific section of preparation, workshop and follow-up, we present how the tool was tested in the case of the neighbourhood of Ydalir in Elverum, Norway.

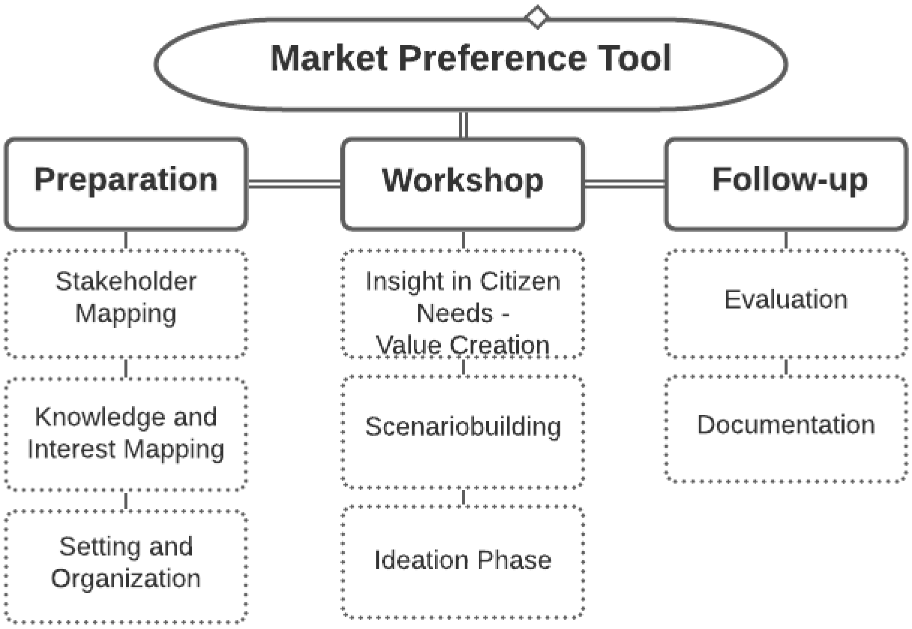

Fig. 2: The MPT tool

5.3.1 Preparation

If not done earlier in the projects timeline, a systematic review of stakeholders through stakeholder analysis is an important first step to identify which stakeholders to invite to the workshop and their status of knowledge. Stakeholder analysis consists therefore of a mapping of stakeholder and their knowledge and interests. In preparation of the workshop and its elements, the stakeholder analysis should include a short description of knowledge and interests of the respective stakeholders. The identified status of knowledge and interest is guiding the need of knowledge to be presented at the workshop.

As the Ydalir project is spanning over several years and new stakeholders or different persons are representing organisations, preparation is an important step in a project with a long timeline for completion. Based on stakeholder mapping, relevant stakeholders were identified and sorted by their relevance to the specific topic of the workshop. Relevant stakeholder groups (six groups) were identified, and they attended the workshop in different numbers: landowners/developers (6), (municipal) administration and project development (7), architects (2), energy sector (2), marketing (2) and complementary financial sector (1). In total 20 participants attended the workshop in addition to five researchers.

The mapping of stakeholders is accompanied by a mapping of existing knowledge of the stakeholders on the project development itself, its history and concepts relevant for the workshop topic. In the case of Ydalir, this mapping was done by the project owner. As relevant knowledge inputs, the status of the neighbourhood development of Ydalir and the results of a former workshop from 2017 on branding were identified. These both were presented by the project owner at the workshop. Additionally, new knowledge inputs as co-benefits of integrative neighbourhood development or best practices for city- and neighbourhood marketing activities were presented by external actors to provide workshop participants a deeper insight in these topics and concepts to enable them to ideate within new knowledge frames.

5.3.2 Workshop

The workshop itself builds on three elements: Firstly, to get insight in citizens' needs, secondly to develop a joint idea of the future neighbourhood in line with citizen needs, and thirdly to ideate concrete action points on further process and marketing activities. Tab. 1 presents the knowledge input from external or internal sides of the project stakeholders involved and the techniques used for learnings and knowledge production during the workshop.

Workshop phases/ Knowledge development	1. Insight in citizen needs	2. Scenariobuilding: Define solutions and benefits of future neighbourhood	3. Ideation Phase
Knowledge input – extern: from the external actors	Elements of wellbeing concept, double-loop learning concept, co-benefits	--	Best practice for city and neighbourhood marketing activities
Knowledge input – intern: from the internal actors	--	Status of Ydalir development, Masterplan of Ydalir, former work on branding and marketing	--
Techniques to gain new knowledge and experience	Role cause analysis/ 5 whys technique, role changing	Scenario-building, role play: tell a friend, double-loop learning	Brainstorming, visualisation, pitching

Table 1: Workshop phases

During the first part of the workshop - insight in citizen needs - we started with a role-change, where participants change role from being a professional person to a private person, and describe elements they like about their home, neighbourhood and city. Building on the descriptions of this "elements of wellbeing", the participants worked with a root cause analysis facilitated by the 5 whys technique to identify needs and values. This task laid the basis for double-loop learning activities facilitated in the second part of the workshop. Additionally, the participants were introduced to the concepts of double-loop learning, elements of wellbeing and co-benefits especially related to technical solutions to give them deeper background insight and enable them to adopt these learning when creating future scenarios of Ydalir in part two.

The second part of the workshop was dedicated to develop a vision of the future neighbourhood of Ydalir in 2030. The starting points were the seven categories of the ZEN neighbourhood definition (see 2.1), and a best-case scenario for Ydalir in 2030 was developed in groupwork in four groups. Each group consisted of participants from the six different stakeholder groups (see 5.3.1) to enable for social learning across sectors and disciplines. The results of the group work were presented in a role play, facilitated as "tell a friend" play, where the participants had to convince a friend to move to Ydalir in the year 2030. Due to covid 19 restrictions, we had to stick to the groups and could not form new groups during the workshop, which would enable for more learning activities a cross the groups and its participants.

While the first two parts of the workshop were dedicated to develop a deeper understanding of citizen needs and values and how a zero emission neighbourhood could respond to them, the last part was dedicated to describe the way forward, the process ahead and marketing activities to be implemented to gain more interest of potential buyers. The workshop itself should ideally be facilitated by a neutral person – in our case the researchers of the ZEN Centre facilitated the workshop. All group and individual work was done with tactile and artistic elements as visualisation on post-its and sheets or role play to facilitate learning.

5.3.3 Follow-up

After the workshop, two elements are important to conduct. An evaluation of the workshop itself to gain insight and feedback on results and effectiveness, potentially missing points and to catch up ideas and thoughts that have been developed by the participants after the workshop. A proper documentation of results and a summary of key results need to be shared with workshop participants and ideally must also be communicated to stakeholders that did not participate in the workshop and to the local community.

In the Ydalir case, we conducted an evaluation of the workshop with help of a web-based questionnaire. The questionnaire had an open research design with qualitative questions regarding the learning and knowledge development of the participants, the workshop design and its organizational implementation. Ten participants (50% of total number) from all stakeholder groups responded to the questionnaire. The answers of the participants shows that the intended knowledge development and learning arose. Participants emphasized that they got new knowledge on the Ydalir project and inspiration from new concepts and best-practice projects. Insight in other participants and citizens mindset and interests, was realised during the workshop as expressed by one participant who represented developers: "Learned a lot about marketing and how those who work with it think". Double-loop learning happened as participants started to reflect on own attitudes and perceptions, as a participant from administrational side expressed: "For me, as I come from marketing, it was completely new knowledge that in such [neighbourhood development] projects it is everyone and not just a specific focus group - and this was completely new to me."

6 ANALYSIS AND DISCUSSION

As we have seen earlier, the MPT tool has 3 elements, namely preparation, workshop, and follow-up. The focus of this paper is on the main element: Workshop.

During the first part of the workshop – where the participants changed their roles from a professional person to a private person, and described elements they like about their home, neighbourhood and city – the participants could get the opportunity to reflect and learn. When they tried to describe likable aspects of their home, city, etc., they could then structure and formulate the likable aspects. Structuring and formulating thoughts, which are often abstract, is itself a learning process, and it can lead to obtain new understanding or perspective.

During the second part, there were, among other things, groupwork and role play. Groupwork that consisted of participants from diverse branches and backgrounds was aimed at facilitating collective reflection and discussion, and hence creating new knowledge and understanding. In other words, social learning took place through interaction with other participants in the workshop. Knowledge is continuously reproduced and potentially transformed during interaction between people (Stacey, 2001). The way people interact – communicate, respond and discuss – with each other plays a key role in creating new knowledge.

This new knowledge could enable the participants to capture a holistic understanding of the discussed matter, think out-of-the-box- and trigger double-loop learning. Varying views expressed in the groupwork and discussions during the role play (convincing a friend to buy a house) could challenge the participants' pre-established understanding and norms, and lead the participants to reflect on questions such as "why do we do what we do?" and "why do we do it the way we do?" These questions can facilitate critical reflection on the existing values and norms, and hence promote double-loop learning. Asking the fundamental and critical questions can be seen in connection with a description that Schön (1998) mentions regarding reflection of a practitioner: "A practitioner’s reflection can serve as a corrective to over-learning. Through reflection, he can surface and criticise the tacit understandings that have grown up around the repetitive experiences of specialised practice and can make new sense of the situation of uncertainty or uniqueness which he may allow himself to experience" (Schön, 1998, p. 61). The description points out the importance of being expose to diverse views and critical reflection in finding new ways to approach and tackle the situation at hand.

From the Ydalir case, we found out that the intended learning is created with the help of the MPT tool. The learning that happened in the workshop is an important part and ingredient of capacity building, which could lead to innovation. This learning can be viewed in connection with three learning traditions that can be applied to collaborative work settings to accomplish a task related to sustainability transitions. The three learning traditions are: Collaborative, organizational and social learning in natural resource management (Mierlo and Beers, 2020).

When discussing collaborative learning, Mierlo and Beers (2020) say that interaction in heterogeneous groups – compared with interaction in homogeneous group – can lead group members to develop more understanding, knowledge, and competence. Different views and understanding that emerge from a heterogeneous collaborative setting can direct group members to reflect upon their own understanding of the reality from different (others') perspectives, develop a holistic picture of the situation and thus make sense of the situation. Application of the MPT tool – especially, the workshop – demonstrates this point. When it comes to organizational learning, the authors discuss the role of single- and double-loop learning in changing practices in organizations. New understanding that arose from communication, reflection and interaction in the workshop suggests that the workshop is conducive to single- and double-loop learning. When describing social learning in natural resource management, the authors point out that "the literature typically views social learning in terms of its inputs and outcomes, with stakeholder diversity (knowledge, interests, values, resources) as input and novel solutions to complex social problems as outcomes" (Mierlo and Beers, 2020, page 262). Diversity of the participants in the workshop (see 5.3.1) and the statements form the participants (see 5.3.3) depict the relevance of social learning. In our view, these three learning traditions seem to overlap each other, at least to some extent.

Mierlo and Beers (2020) also differentiate two major modes of learning in transitions:

- Discursive interaction: This is mainly about exchanging information, knowledge and meanings, and creating a common ground for understanding.
- Reflective action: This primarily deals with searching for viable and applicable solutions, and engaging in an iterative process of action and reflection that involves activities of planning, action and evaluation that can lead to change practices.

According to the authors, discursive interaction is a part of reflective action. The workshop encompasses these two modes of learning in transitions. When it comes to reflective action, it is to be noted that the last part of the workshop was dedicated to describe the way forward, the process ahead and marketing activities to be implemented to gain more interest of potential buyers.

7 CONCLUSION

This paper looks at how professional stakeholders such as developers, landowners, planners, civil servants can gain more insight and knowledge on user needs and values to create solutions within neighbourhood developments that are in line with user needs and thereby foster public value creation. In this regard, application of a tool (the MPT tool) in a case project was presented and discussed with using relevant concepts.

Building on literature study on (social) learning and findings from a case study of a ZEN neighbourhood, we presented a concept for a workshop as a tool to get deeper insight in citizens' needs and how professional stakeholders of a ZEN neighbourhood could respond to those needs. This tool has to be seen as one tool among others and the results should be verified by citizens. This tool is not replacing citizen participation.

This paper aimed at contributing to elaborate on learning within multi-stakeholder settings and focused especially on capacity building among professional stakeholders. Additionally, we provide practical guidance for using a tool that can be seen as a contribution to approaches towards stakeholder participation and for a methodology of local context-based tools for social learning.

Poeck et al. (2020) point out that empirical research on learning in transition initiatives is rare. This paper and the study associated with it can be considered as a contribution to this research field.

About further research:

- As this workshop was facilitated by researchers, we will discuss the setting and factors necessary to implement this workshop by diverse stakeholders in detail at a later point of time.
- The presented study is embedded in an ongoing research project on market preferences for Zero Emission Neighbourhoods. Results from other future workshops (applying the MPT tool) will be studied to find out more about the application of the MPT tool and its effects in diverse settings.

8 ACKNOWLEDGEMENTS

This paper has been written within the Research Centre on Zero Emission Neighbourhoods in Smart Cities (FME ZEN). The authors gratefully acknowledge the support from the ZEN partners and the Research Council of Norway.

Integration of Multi-dimensional Rural and Urban Planning Efforts for Achieving SDG 13 – Indian Context

Piyali Bandyopadhyay

(Dr. Piyali Bandyopadhyay, Project Scientist, Central Pollution Control Board, New Delhi, piyali.moef@gmail.com)

1 ABSTRACT

Earth's climate is dynamic phenomenon subjected to change through natural cycle and anthropogenic influences. Rapid urbanization and industrialization have accelerated the process of climate change. During last few decades world has become more concerned about changes in climate, popularly known as Global Warming. Every sphere of life is affected through climate change. Prime anthropogenic reason for climate change is accumulation of Green House Gases due to burning of fossil and fuel. As per estimation of World Bank half of the world's population lives in cities, a share that is likely to reach 70 per cent in 2050 (World Bank 2010). Cities utilize as much as 80 per cent of worldwide energy production and account for a roughly equal share of global greenhouse gas emissions. Urban population is expected to be double by 2030 however; the global built-up area is expected to triple during the same period (Angel et al. 2005).

Sustainable Development Goal 13 (SDG13) talks about climate change action plan, it is one of the 17 Sustainable Development Goals established by United National during 2015. SDG13 invites Governments to "take urgent action to combat climate change and its impacts". It emphasizes addressing and minimizing the risks arised due to climate change and is integral to the successful implementation of SDGs. Scope of SDG13 comprises multi-dimensional focus which inter alia includes adaptation and mitigation, mainstreaming climate concerns in development policies and discussing financial mechanisms to meet the targets.

Cities are hubs of opportunities for livelihood, therefore, it attract population for migration. Cities are drivers of global climate change and at the same time it is most affected party. Rapidly growing cities in developing countries and emerging economies with limited infrastructure very often become unsuccessful to provide adequate protection from extreme weather events and changing climatic conditions. The urban poor are particularly most vulnerable towards extreme weather events as they are more exposed to these events. In many cities, unplanned and haphazard urban growth leads to rapid urban sprawl, pollution, and environmental degradation. To meet the demand of urbanization issues related to climate change is largely under estimated. Peri urban areas are the most dynamic space in the process of urbanization, encounter land use change, haphazard development without prefeasibility study. These areas need special attention for mitigation and adaptation for climate change.

Rural ecosystem of India possesses unique physical, social and economic characteristics which make them uniquely vulnerable to the impacts of climate change. Impact of climate change in rural areas involves major questions of detection and attribution. Whilst having potential, there are complications with using traditional knowledge and farmer perceptions to detect climate trends (Rao et al., 2011; in IPCC 2014). Climate Change impact may be categorized into two segments, i.e. first sort involves extreme events, such as floods and storms, as they impact on rural infrastructure and cause direct loss of life and second sort will involve impacts on agriculture or on ecosystems on which rural people depend.

Sustainable development, climate change impacts and disaster risk management are core issues for both rural and urban areas of India. Vulnerability due to climate change is a dynamic concept, varies spatially as well as temporally with sensitivity, exposure and adaptive capacity. In case of urban areas climate change responsive city plan should not be confined within city administrative boundary it should encompass peri-urban areas. Similarly for climate change responsive rural planning efforts may integrate climate change issues with rural employment, infrastructure development, natural resource management, basic need development programme, etc.

Various initiatives like, Smart City Mission, National Urban Information System, Environmental Information System, National Spatial Data Infrastructure, Atal Mission for Rejuvenation and Urban Transmission, Rurban Mission, etc. are implemented by the Government of India toward sustainable rural and urban development. But in these rural and urban planning programmes issues related to climate change are not addressed. Details study of these programmes/ schemes reveals the scope of integration of climate change related issues with exiting planning initiatives. For achievement of SDG13 there is need to integrate

these initiatives along with climate change responsive plan for both rural and urban areas. . In this article an attempt has been made to develop a methodology for preparing cross sectoral and multi-dimensional planning model for climate change responsive planning for rural and urban areas.

Keywords: Rural Planning, Urban Planning, Peri Urban, Vulnerability, Adaptation, Mitigation

2 BACKGROUND

Climate Change is primarily the outcome of accumulation of Green House Gases (GHG) in atmosphere. The global increase in carbon dioxide concentration is basically due to burning of fossil fuel and landuse change, while those of methane and nitrous oxide are primarily due to agriculture activities. 'Global Warming' is a specific example of broader term 'climate change' and refers to observe increase in average temperature of air near earth's surface and oceans in recent decades. It's effect particularly on developing countries is adverse as their capacity and resources to deal with the challenges are limited' (India, Ministry of Environment and Forest, Annual Report, 2012-13:349). Scientific studies have shown that the global atmospheric concentrations of carbon dioxide, methane and nitrous oxide which are the most important Green House Gases, have increased sharply as a result of human activities since 1750 and now far exceed pre-industrial values.

During 1988 Intergovernmental Panel on Climate Change (IPCC) was established for assessing "the scientific, technical and socio-economic information relevant for the understanding of the risk of human-induced climate change". Based on the analysis of data and information for several decades IPCC in its Fourth Assessment Report has said that the incident of climate change is evident everywhere on the planet. Its impact is vivid from the depths of the ocean up to troposphere. In this report, Working Group Summary for Policymakers had synthesized current scientific understanding of global warming and also projects future climate change. It says that emissions of heat-trapping gases from human activities have caused "most of the observed increase in global average temperatures since the mid-20th century". Evidences say that human activities are the prime cause of recent climate change and are even stronger than prior assessments.

According to IPCC assessments the degree of climate change in coming decades is directly related to emission scenario. It means, if emissions from various sources like transportation, power plants, landuse, etc., are reduced then some degrees of warming will still continue because past emissions will persist in the atmosphere for decades or more. Another scenario is that, if no action is taken to reduce emission, there will be twice as much warming over the next two decades than efforts taken to stabilize heat-trapping gases and other climate relevant pollutants in the atmosphere at their year 2000 levels.

Sustainable Development Goal 13 (SDG13) is one of the 17 Sustainable Development Goals established by United Nation during 2015. SDG13 invites Governments to "take urgent action to combat climate change and its impacts". It emphasizes addressing and minimizing the risks arise due to climate change and is integral to the successful implementation of SDGs. Scope of SDG13 comprises multi-dimensional focus which inter alia includes adaptation and mitigation, mainstreaming climate concerns in development policies and discussing financial mechanisms to meet the targets. Targets of Goal 13 comprises Strengthen resilience and adaptive capacity to climate-related hazards and natural disasters in all countries (13.1), Integrate climate change measures into national policies, strategies and planning (13.2), Improve education, awareness-raising and human and institutional capacity on climate change mitigation, adaptation, impact reduction and early warning (13.3), Implement the commitment undertaken by developed-country parties to the United Nations Framework Convention on Climate Change to a goal of mobilizing jointly $100 billion annually by 2020 from all sources to address the needs of developing countries in the context of meaningful mitigation actions and transparency on implementation and fully operationalize the Green Climate Fund through its capitalization as soon as possible (13.3a), Promote mechanisms for raising capacity for effective climate change-related planning and management in least developed countries and small island developing States, including focusing on women, youth and local and marginalized communities(13.3b). SDG 13 targets emphasize on capacity building , awareness generation along integration of climate measures into national policies, strategies and planning. The successful implementation of the targets demands mainstreaming of climate concerns not only in national policy making process but also at rural and city planning.

3 OBSERVATIONS ON CLIMATE CHANGE EVENTS IN INDIA :

According to India’s Initial National Communication, 2004 (NATCOM) to UN Framework Convention on Climate Change (UNFCC) observations are as follows:

Surface temperature: Over the past century the average surface air temperature has increased by 0.4oC across the country. The subcontinent is withstanding two different trends in change of surface air temperature. A warming trend has been recorded along the west coast, in the central part of the country, peninsular India and in the north-eastern region of country. While cooling trend in the surface air temperature is prevalent in north-west and parts of southern India.

Prakasa Rao et al. (2004) examined the effect of urbanization on the meteorological parameters at fifteen Indian cities and found that radiation values, bright sunshine hours, wind speeds and total cloud amounts have a decreasing tendency during the last 40–50 years, whereas relative humidity and rainfall amounts show increasing tendency in some cities. The impact of climate change may differ from one region to the other, specially for a geographically complex country like India.

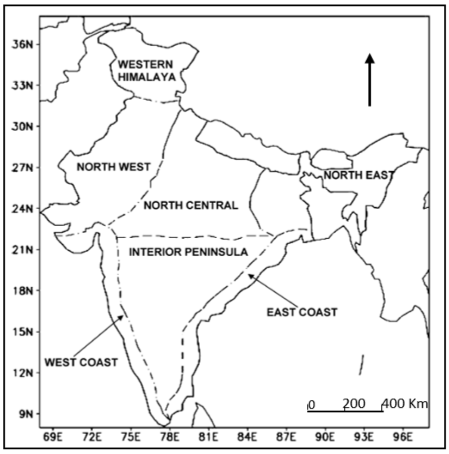

Fig. 1 : Seven homogenous regions of India used for examining temperature trends. Source: IITM.

India has been divided into seven zones as shown in Fig.1.0 to examine the changes in maximum and minimum temperatures over these regions. Seven identified zones are north-west, western Himalaya, north central, north-east, interior peninsula, east coast and west coast. West coast shows maximum increase in its maximum temperature by about 1.2°C followed by 1°C in the north east, 0.9°C in the western Himalaya, 0.8°C in the north central, 0.6°C in the north west, 0.6°C in the east coast and the least amount of 0.5°C in the interior peninsula.

- Rainfall: At the national level monsoon rainfall does not show any significant trend while at the regional level rainfall anomalies have been observed. The areas along the west coast, northern Andhra Pradesh and north-western India have increasing trend of monsoon rainfall (+10 per cent to +12 per cent of the normal over the last 100 years) while eastern part of Madhya Pradesh, north eastern India and some parts of Gujarat and Kerala are receiving less monsoon.
- Extreme weather events: The weather reports of the previous century do not indicate any significant long term trend in the frequencies of large-scale drought and floods. During the last two decades, however, the incident of more frequent droughts followed by less severe droughts become common phenomena. The coastal areas of the country experience increase trend in severe storm at the rate of 0.011 events per year (MoEF&CC).West Bengal and Gujarat have reported increasing trends severe storm while Orissa is experiencing decline trend. The analysis of daily rainfall data set have shown (i) a rising trend in the frequency of heavy rain events, and (ii) a significant decrease in the frequency of moderate events over central India from 1951 to 2000 (Goswami et al 2006).
- Rise in sea level: Based on the records of coastal tide gauges in the North Indian Ocean for more than 40 years Unnikrishnan and Shankar have estimated sea level rise was between 1.06 -1.75 mm per year. These rates are consistent with 1-2 mm per year global sea level rise estimates of IPCC.
- Impacts of Himalayan Glaciers: The Himalayas posses one of the largest resources of snow and ice and its glaciers form a source of water for the perennial rivers namely Indus, Ganga, Brahmaputra,

etc. Glacial melt may impact their long –term lean –season flows, with adverse impacts on the economy in terms water availability and hydropower generation. The monitoring data on the spatial extension of glacier in the Himalayan regions shown recession of some glacier in recent year, the trend is not consistent across the entire mountain chain.

Based on the increase trend in concentration of atmospheric GHG, various studies are undertaken by scientists to project future change in climatic characteristics. Some of the observations are listed below:

- As per IPCC's projection annual mean surface temperature increase will range from 30C to 50C under A2 scenario and 2.50C to 40C under B2 scenario while Indian Institution of Tropical Meteorology (IITM), Pune forecast more pronounced worm in the northern parts of India.
- IITM, Pune indicated that summer monsoon intensity may increase beginning from 2014 and by 2100 under A2 scenario of IPCC.
- Changes in frequency and / or magnitude of extreme temperature and precipitation events. Some results show that fine scale snow albedo influence the response of both hot and cold events and that peak increase in extreme hot events are amplified by surface moisture feedbacks.

3.1 Possible Impact of Projected Climate Change

Impact on water resources: Changes in climatic factors like, temperature, precipitation, humidity will have long term impact on quality and availability of water. The decrease in snow cover in the Himalayan region will affect the availability of water in the rivers systems like Brahmaputra, Ganga, during the lean season. NATCOM has projected a decline in total run-off for all river basins, except Narmada and Tapti. The decline in run-off is also estimated by more than two-thirds for the Sabarmati and Luni basins. Intrusion of sea water due to sea level rise will affect the costal fresh water sources.

Impacts on agriculture and food production: The agricultural yields are subjected to the variation in monsoon rainfall and seasonal temperature change. Studies by Indian Agriculture Research Institute (IARI) and others forecast greater expected loss in Rabi crop. It says 1oC rise in temperature reduces wheat production by 4-5 Million Tonnes. Small changes in temperature and rainfall have significant impact on quality of fruits, vegetables, tea, coffee, aromatic and medicine plants and basmati rice. Other impacts on agriculture and related sectors include lower yield from dairy cattle and decline in fish breeding, migration and harvests. Global reports show a loss of 10-40 per cent in crop production by 2100.

Impact on health: Change in climatic pattern may have also impact on distribution of important vector species and may increase the spread of such diseases to new areas. It is estimated that an increase of 3.8oC in temperature and 7 per cent increase in relative humidity the transmission windows i.e., months during which mosquitoes are active will be open for all 12 months in 9 states in India. The transmission windows in Jammu and Kashmir and in Rajasthan may increase by 3-5 months. However, Orissa and some southern states, a further increase in temperature is likely to shorten the transmission window by 2-3 months.

Impacts on forests: Based on the future climate projections, it is estimated that on an average 70 per cent of the forest areas in the country are likely to experience shift in forest types, followed by changes in forests produce, livelihood etc. outcome of NATCOM projects shows an increase in the areas under xeric scrublands and xeric woodlands in central India at the cost of dry savannah in these regions.

Vulnerability to extreme events: Densely populated regions of coastal areas are exposed to climatic events, such as cyclones, floods and drought and huge declines in cultivable areas in arid and semi-arid regions arise during extreme climatic conditions. Vast areas in Rajasthan, Andhra Pradesh, Maharashtra and Gujarat and relatively small areas in Karnataka, Orissa, Madhya Pradesh, Tamil Nadu, Bihar, West Bengal and Uttar Pradesh are frequently affected by the incidents of drought. It is estimated that about 40 million hectares of land is flood prone, including most of the river basins in the north and north eastern belt, affecting about 30 million people on an average each year.

Impacts on coastal areas: By the mid 21st century the mean Sea level Rise (SLR) projected along the India's coast will be 15 – 38 cm and of 46-59 cm by 2100. India's NATCOM assessed the vulnerability of coastal district based on physical exposure to SLR, social exposures to SLR, social exposure based on population affected and economic impacts. In addition, a projected increase in the intensity of tropical cyclones poses a threat to the heavily populated coastal zones in the country (NATCOM 2008).

3.2 India's Action Plan for Climate Change

India's emissions are estimated as 1331.6 million tonnes of the carbon dioxide equivalent Green House Gas (GHG) emissions in 2007. The emissions indicate an annual growth of 4.2 per cent from the levels in 1994. Whereas India's CO2 emissions are only about 4 per cent of total global CO2 emissions and much less if the historical concentrations are taken into account (India, Ministry of Environment and Forest, Annual Report, 2012-13: 349).

In pursuance of the obligations cast on parties to the United Nations Framework Convention on Climate Change (UNFCCC), India has undertaken to communicate information about the implementation of the Convention, taking into account the common but differentiated responsibilities and respective capabilities and their specific regional and national development priorities, objectives and circumstances. The elements of information provided in the communication include a national inventory of anthropogenic emissions by sources and removals by sinks of all Green House Gases, a general description of steps taken to implement the Convention including an assessment of impacts and vulnerability and any other relevant information. India has submitted the Second National Communication (NATCOM) to the UNFCCC in 2012. The first National Communication was submitted in 2004. As per the Second National Communication submitted by India to the UNFCCC, it is projected that the annual mean surface air temperature rises by the end of the century ranges from 3.5 c to 4.3 c whereas the sea level along the Indian coast has been rising at the rate of about 1.3 mm/year on an average. These climate change projections are likely to impact human health, agriculture, water resources, natural ecosystems, and biodiversity (Economic Survey, 2012-13:257).

India's development is closely knitted with its unique natural resources, the huge demand for economic and social development and poverty eradication and its adherence to its civilization legacy that places a high value on the environment and maintenance of ecological balance. Climate change may alter the distribution, quality and quantity natural resources and it will adversely affect the livelihood of its people. Maintaining a high economic growth rate is essential for increasing living standards of the vast majority of our people and reducing their vulnerability to the impacts of climate change. In order to achieve the sustainable development path along with the economic and environment development objectives, the National Action Plan for Climate Change (NAPCC) is guided by the following principles (MoEF&CC, 2014):

- Protecting the poor and vulnerable section of the society through an inclusive and sustainable development strategy, sensitive to climate change.
- Achieving national growth objectives through a qualitative change in direction that enhances ecological; sustainability, leading to further mitigation of greenhouse gas emission.
- Devising efficient and cost effective strategies for endues Demand Side Management.
- Deploying appropriate technologies for both adaptation and mitigation of greenhouse gases emissions extensively as well as at an accelerated pace.
- Engineering new and innovative forms of market regulatory and voluntary mechanism to promote sustainable development.
- Effecting implementation of programmes through unique linkage, including with civil society and local government institution and through public –private –participation.
- Welcoming international cooperation for research, development, sharing and transfer of technologies enable by additional funding and global IPR regime that facilitates technology transfer to developing countries under the UNFCC.

The National Action Plan focuses on the development and use of new technologies. Eight National Missions namely; National Solar Mission, National Mission for Enhanced Energy Efficiency, National Mission on Sustainable Habitat, National Water Mission, National Mission for sustaining the Himalayan Ecosystem, National Mission for Green India, National Mission for Sustainable Agriculture, National Mission on strategic knowledge for Climate Change are identified. Further Indian Network for Climate Change Assessment (INCCA) has also taken steps at the institutional level for conducting research in climate change related sciences and making necessary assessments. The MoEF&CC has already set up a network, namely the Indian Network for Climate Change Assessment (INCCA) comprising of 127 research institutions tasked with undertaking research on the science of climate change and its impacts on different sectors of economy

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

across various regions of India. INCCCA has helped the Ministry to put together its Green House Gas (GHG) Emissions Inventories and in carrying out other scientific assessments at more frequent intervals.

3.0 Impact of Climate Change

3.3 Scenario in Rural India

The word "rural" generally refers to reas of open country, small settlement with primary/ agro – based economic activities. During year 1951 share of urban population in India to total population was 17 percent and it becomes 31.6 per cent during 2011 census. In contrast to this during last 50 years the share of rural population of the country has decreased from 82.0 to 68.9 per cent. The disparity is rate of development, opportunity for livelihood, etc are major reasons for decrease in rural share of population. According to National Sample Survey 64th Round approximately a third of Indians (i.e. some 325 million people, out of a population of 1.14 billion in 2008) are migrants. Employment seems to be the prime force for migration; in rural areas, 55 per cent of the households have migrated for employment related reasons.

Rural ecosystem of India possesses unique physical, social and economic characteristics which make them uniquely vulnerable to the impacts of climate change. Impact of climate change in rural areas involves major questions of detection and attribution. While having potential, there are complications with using traditional knowledge and farmer perceptions to detect climate trends (Rao et al., 2011; in IPCC 2014). Climate Change impact may be categorized into two segments, i.e. first sort involves extreme events, such as floods and storms, as they impact on rural infrastructure and cause direct loss of life and second sort will involve impacts on agriculture or on ecosystems on which rural people depend.

Impacts of climate change on agriculture and related activities are due to rising temperature and changes in rainfall characteristics and seasonality along with extreme events. Changes in temperature and rainfall pattern bring changes in agricultural season. Rural economy is primarily agro based and governed by occurrences of monsoon. According to Central Statistical Organization (CSO) growth in GDP in agriculture and allied sectors in 2014-15 over 2011-12 is -0.1%, share of agriculture and allied sectors in total GDP has reduced by -0.4% .

The reasons for migration in India are usually summarized as push and pull factors. While push factors are mostly convincing reasons which help the migrants to make up their mind for migration. The pull factors offer opportunity and attract migrants towards the place of destination. The push factors include the population pressure, declining yields, institution of marriage, disintegration of joint family system, lack of livelihood opportunities, etc; the pull factors also include better educational, health care facilities, modern means of transport and communications, more employment opportunities and a growing craze for urban life. In addition to these factors, the incidents of climate change is affecting the rural ecosystem in various ways. It is causing flood, drought, sea level rise, etc. These events trigger rural to urban migration. Climate refugees are push migrants , they may be permanent or temporary in nature.

Rural to urban migration is the major reason for urbanization. Rapid growth in urban population is a big challenge to the city administrator to serve housing, infrastructure, environmental quality, etc. to the city dwellers. Rural to urban migration has both positive and negative impacts on urban areas. Due migration of people from rural to urban areas the mushrooming of slums in are around the urban areas/ urban centre takes place. According to the study carried out by economic and social commission for Asia and the Pacific (ESCAP, 1991) "migration from rural to urban areas continues at a rapid pace in many countries of the region, and it was often beyond the capacity of towns, cities and metropolitan areas to cope with the increasing numbers". Increasing inflow of distressed population from rural to urban area results into overcrowding of cities and development of slums. Economically weaker migrants from rural areas come to the urban areas and settle in the slums. It is observed that unskilled marginal farmers or landless labours migrates to the urban areas become unskilled labourers and settle in the slums. The great slums of India are mainly formed because of migration of large numbers of individuals or families to the urban centers in search of their dreams, usually in hunt of better economic prospects/ livelihood (Bandyopadhyay , 2018) .

3.4 Scenario in Urban area

In the recent days a new challenge has been added to urban issues, that is climate change. Its outbreak is in the form of increase in temperature/ occurrence of super storm/flood/drought/ submergence of coastal areas, etc. Coping with climate change remains a daunting challenge. The degree of quandary that cities are facing due to climate change has made the urban sustainability a big question.

The majority of the world's population already lives in urban areas and it will become 66 per cent by 2050. Cities consume up to 80 per cent of total global energy production and account for 71 to 76 per cent of global CO2 emissions (Gerics 2015). They are the drivers of global climate change and at the same time it is most affected party. Rapidly growing cities in developing countries and emerging economies with inadequate infrastructure fails to provide adequate protection from extreme weather events and changing climatic conditions. The urban poors are particularly most vulnerable towards extreme weather events as they are more exposed to these events. In many cities, unplanned and haphazard urban growth leads to rapid urban sprawl, pollution, and environmental degradation. In addition, cities are points of convergence of many risks, which makes them particularly vulnerable to chain reactions and amplify the interconnection between global risks (World Economic forum 2015) such as natural hazards and climate change impacts. The concentration of people, assets, critical infrastructure and economic activities in cities exacerbates the potential of natural hazards (Gerics 2015). Asia, Africa and Latin America have experienced high rates of increase in the incidence of natural disasters over the last three decades, with many urban areas having sustained heavy losses of human lives due to disasters. Total population exposure to cyclones and earthquakes, is projected to rise (Lall & Deichmann, 2009). Many of the world´s cities are situated along the coast, they are exposed to flood from storm surges and sea level rise. The risk of coastal flooding has further increased in cities affected by subsidence. Coastal cities of South America have to face more frequent heavy rainfall and higher temperature which could put thousands of homes in the low-income settlements at risk (United Nation 2011).

The International Council of Local Environmental Initiatives (ICLEI), South Asia, associated with 54 local governments in the South Asian region (including 41 cities from India) to collect city energy consumption and related carbon emissions inventory data of the participating cities (Figure 2.0).

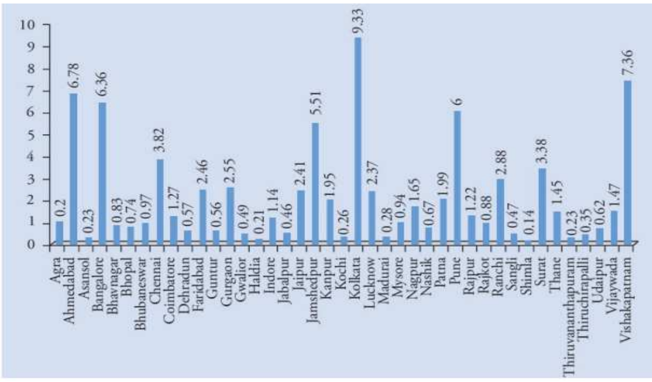

Fig. 2: City-wise energy consumption and related carbon emissions inventory data.

It shows the highest emissions are in Kolkata, followed by Vishakapatnam and Agra. It is found that the average per capita carbon emissions are higher in the metropolitan cities of India (being 1.19 tonnes per capita as compared to only 0.90 tonnes per capita in the non-metropolitan cities) and the national average is 0.93 tonnes per capita (Sridhar, Kala Seetharam, 2011). This is because larger cities have more industries and other polluting activities such as emissions from public and private transport. However, the corporation level emissions as a percentage of city-level emissions are much higher in the non-metropolitan areas than in the metropolitan areas. This is because smaller city corporations lack the adequate technology to minimize their carbon emissions in the provision of various public services such as water supply, sewerage, street lighting, and transportation. Not only cities and urbanization impact climate change, but also, the question of whether climate change has impact on cities India's cities which are characterized by high density of population, housing stock, and poor infrastructure, all these make them more vulnerable to climate change. Given that the most valued infrastructure is usually located in cities, the economic and social costs of climate change will be much higher in cities. For example, cities house valuable communications infrastructure as they do physical infrastructure such as buildings, roads, bridges, and fly-overs. Hence, any climate change impacts in the form of damage will be quite expensive. Revi (2009) highlight the multiple ways in which climate change can impact Indian urban residents through loss of livelihood opportunities (including housing and assets) and income, loss in terms of health or ability to work, loss of community and informal social nets due to forced migration, reduced resilience to future shocks, reduced affordability and access to public

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

services, and greater vulnerability to unsustainable debt exposure, that could be necessitated in times of crisis. There is nothing uniquely urban about these phenomena and these channels can work equally in rural areas. Second-order impacts of climate change on Indian cities as occurring via migration, since climate change can accelerate the pace of rural–urban migration, driven by increases in extreme events, greater monsoon variability, drought, flooding, and resource conflict, as well as loss of both livelihood opportunities and informal social nets, especially due to sea-level rise and enhanced flooding in cities by the coasts, leading to changes in the spatial distribution and density of both formal and informal settlements. Degradation of building and infrastructure materials is also projected to occur. As warmer temperatures extend into higher latitudes, diseases that have long been considered eradicated may re-emerge; and new diseases may also be experienced. The health ramifications could be serious. The gap between water supply and demand is also projected to increase as drought-affected areas expand and the episodes of flood intensify.

4 OVERVIEW OF PLANNING INITIATIVES IN INDIA IN CONTEXT OF CLIMATE CHANGE

4.1 Rural Development Initiatives in India

With the objective to improve rural economy, Govt of India has implemented numerous initiatives likes; Community Development Programme, Twenty Point Programme, Drought Prone Areas programme, Desert Development programme, National Fund for Rural Development, Council for Advancement of People's Action and Rural Technology, Har Khet ko Pani, Mahatma Gandhi National Rural Employment Guarantee Scheme, etc.

During 2016 Government of India has launched National Rurban Mission to develop cluster of villages that preserves and nurtures the essence of the rural community life with prime focus on equity and inclusiveness without compromising with the facilities perceived to be basically urban in nature thus creating a cluster of 'Rurban Villages'.

An Integrated Cluster Action Plan (ICAP) for each Rurban cluster would be prepared to guide the development of the village cluster. ICAP is a key document comprising baseline studies of the cluster and the key interventions needed to address these needs and to leverage its potential. The ICAP prepared for the cluster includes: (1) A strategy for the cluster integrating the vision for each Gram Sabha (village level administrative body elected by villagers) identified in the cluster. (2) The desired outcomes for the cluster under the Rurban Mission (3) The resources to be converged under various Central Sector, Centrally Sponsored and State Sector schemes. (4) The Critical Gap Funding (CGF) required for the cluster. (5) Most importantly, the ICAP would delineate the cluster areas to form well planned layouts following the planning norms (as laid down in the State Town and Country Planning Acts/similar Central or State statutes as may be applicable), which would be duly notified by the State/UTs. These plans would be finally integrated with the District Plans/Master Plans as the case may be. ICAP for each cluster will contain two components ; Socio-economic components and infrastructure component and Spatial Planning Components.

4.2 Rural Planning Initiatives in the light of SDG13

Government of India has undertaken numerous initiatives towards infrastructure development, economic up-gradation, increase in agricultural production, spatial area development, socio-economic development, community development, etc. These efforts are disjointed and target based, lack of considering all aspects of rural development .

National Rurban Mission has scope for development of village cluster, it focuses on development of village cluster socially as well as economically. In National Rurban Mission villages clusters are considered as unit of planning. 300 villages clusters are identified for development . The Mission not only focuses on reducing regional disparity but also it focuses on social development . It has scope for development of spatial data , resource map, cluster profile for demography, socio-economy, culture, administrative profiles of the clusters, etc. The Mission has also embedded components like; training for economic activities, developing skills and local entrepreneurship and infrastructure amenities. For each cluster the comprehensive assessment are made on economic profile of the cluster to understand drivers of economic growth of the cluster, assess the basic strengths and weakness of the cluster and identify the opportunities for economic growth of the cluster. This exercise will not be restricted at the cluster level and will include economic assessments at the block and district levels. The cluster level strength and deficiency analysis and identification of needs are integrated with the ongoing schemes of the Government of India. Resources for cluster development would be converged under various ongoing central and state level schemes. For implementation of the mission, bottom to top integration approach is adopted.

Though objective of National Rurban Mission is not directly focusing on climate change related issues but it has scope to accommodate the tasks and targets for achieving SDG 13 Goals.

4.3 City Planning Initiatives in India

Since independence various initiatives are taken by Government of India for city/ urban planning which, inter alia, include National Commission on Urbanization, 74th Constitutional Amendment Act, Urban Development Plan Formulation and Implementation Guidelines, Jawaharlal Nehru National Urban Renewal Mission, National Urban Information System, Rajiv Awas Yojana, National GIS, Smart City, Swachh Bharat, Atal Mission for Rejuvenation and Urban Transformation, etc

Government of India had appointed National Commission on Urbanisation during 1980s under the Chairmanship of Charles Correa to analyze the state of urbanization with reference to the demographic, economic, infrastructural, environmental, physical, shelter, energy, communication, land, poverty, aesthetic and cultural aspects and to identify priority action areas and it had also made projections of future needs and estimated the available resources. On the basis of analysis carried out by the Commission it had prepared basic guidelines for the specific action plan in priority areas along with policy frames and suggestion of basic approaches for the encouragement of manageable urbanization and also the methods of creating networks of interactions as an ongoing process among government, academic and research institutions and citizen groups. The recommendations of the Commission had not been finalized and yet to be implemented as policy.

The Constitution (Seventy Forth Amendment) Act, 1992 has introduced a new part namely, Part IXA in the Constitution, which deals with the issues relating to municipalities. The main provisions introduced by Act are constitution of municipalities, composition of municipalities, composition of ward committee, duration of municipalities, etc. This amendment has provided a constitutional form to the structure and mandate of local bodies. It has made urban local bodies to perform as democratic and self governing institution at grassroot level.

Since 1996, due to rapid growth of population and reasons like globalization and liberalization, the towns and cities have become more dynamic in nature. Urban areas are subjected to challenges in terms of requirements of infrastructure and other basic services and amenities. The Urban Development Plan Formulation and Implementation (UDPFI) Guidelines have been framed to incorporate the provisions of the various legal and policy/ guidelines of the respective Ministries and departments, best practices of the States as examples and the planning system in vogue. An interrelationship between them is proposed for a sustainable urban and regional development.

Jawaharlal Nehru National Urban Renewal Mission (JnNURM) was launched in 2005 to encourage cities to commence steps for bringing phased improvements in their civic service levels. The mission of JnNURM was to development in the context of urban conglomerates focusing to the Indian cities. JnNURM aims at creating ‘economically productive, efficient, equitable and responsive Cities’ by a strategy of upgrading the social and economic infrastructure in cities, provision of Basic Services to Urban Poor and wide-ranging urban sector reforms to strengthen municipal governance in accordance with the 74th Constitutional Amendment Act, 1992.

National Urban Information System (NUIS) initiated by Ministry of Urban Development (MoUD) in 2006 for creation of multi-scale (1:10,000, 1:2000, 1:1000) hierarchical urban geospatial database on thematic content using satellite, aerial and GPR techniques. It generated GIS based maps for preparation of Master Plan for selected cities.

Rajiv Awas Yojana (RAY) was launched in 2009 as a continuation of JnNURM. It envisages a “Slum Free India" with inclusive and equitable cities where every citizen has access to basic civic infrastructure and social amenities and decent shelter.

Ministry of Urban Development during 2015 has launched the Smart city mission transformation with the objective to support cities to enable them to offer core infrastructure and provide a decent quality of life to its citizens along with a clean and sustainable environment and application of ‘Smart’ Solutions. The aim is to achieve sustainable and inclusive development. The mission aims to develop a replicable model which will act like a light house to other aspiring cities.

During 2015 the Ministry of Urban Development has launched Atal Mission for Rejuvenation and Urban Transformation (AMRUT) with the aim to formulate GIS-based Master Plan for selected AMRUT cities. The geospatial technologies is used for formulate a master plan for decision-making, effective land use management and utilization, spatial growth management, enable project planning and urban management.

4.4 City planning initiatives in the light of SDG 13.

Addressing climate change related issues for urban areas emphasize to integrate city planning programmes and climate change indicators as important input for decision support systems for city planning. Thorough review of city planning initiatives reveals that approach of city/master planning exercise is compartmentalized by nature and having prime focus on landuse, infrastructure, industrial, transportation development, etc. To meet day to day demand for urban life the vulnerability of the city arise due to climate change has become underestimated.

Non-consideration of climate change issues in city planning is mainly due to limited knowledge of climate change adaptation mechanisms. The measures identified by the researchers/ stakeholders deal mostly with mitigation (afforestation, sustainable transport, etc.) and not with adaptation initiatives. Knowledge about possible adaptation mechanisms specific to the local context is missing. Another reason is lack of information and mechanism for information exchange. One of the emerging gaps is lack of reliable, accessible data sets. While some data are available with Government and also with a couple of NGOs. The main issue is non-availability of reliable data in public domain. Most of the information available with the Government of India can be accessed through the Right to Information Act. But it remains a project in itself to access and collate the data available in different places, especially, when spatial data is required for planning at a city level. By using spatial data sets available in public domain some of the constraints can be overcome. Lastly, it is attributed to limited planning capacities, restrictive planning processes and institutions. Most of the cities have limited internal capacity to plan beyond the immediate project at hand. Moreover, the planning process itself is protracted and still driven primarily by landuse planning that often fails to incorporate the current risks and resource constraints. The institutions dealing with planning are fragmented, like the municipal corporations, the development authorities and the town planning institutions all have a role to play.

Though protocols of ongoing city planning initiatives like; NUIS, AMRUT, Smart City etc. are not directly addressing climate change related issues of urban areas but within their protocol there is scope to incorporate aspects of climate change responsive planning without hampering the basic structure of the scheme.

5 INTEGRATED MULTIDIMENSIONAL MODEL FOR RURAL AND CITY PLANNING

In previous segments it is understood that impacts of climate change are vivid in both urban and rural lives of India . Climate change is acting as one of the push factors for rural migrants, generating addition burden to urban infrastructure, peri urban growth, haphazard development, poor quality of life, degradation of natural resources , environmental degradation etc. ICAP for rural areas and NUIS, AMRUT, Smart City, etc for urban areas have scope to incorporate targets of SDG 13 in their exiting planning mechanism. There is requirement of integrated multidimensional planning model for rural and urban planning which will knit climate change related issues with exiting planning mechanisms.

The model will be a rational approach to understand and assess the risks of climate change, policy to reduce the impact of climate change and lessen the causes behind climate change at city and rural levels. The components of the integrated multidimensional model will be assessment of risk, policy to reduce the risk, approaches to reduce the impact of the hazard and last not the least to diminish the functions accelerating the process of climate change. Performance of these tasks entails data and information from various aspects of both rural and city life, its environment and factors influencing GHG emission.

The major theoretical challenge involves in implementation of integrated multidimensional planning model is development of multidisciplinary approach that integrates diverse rural and urban themes such as social, economic, cultural, environmental, spatial and physical infrastructure into a unified conceptual framework capable of understanding present state of resiliency of any geographical area and how they should move towards a more resilient state. The integrated multidimensional planning model aims to investigate the phenomenon of present resilience and developing a new multidisciplinary conceptual framework towards more resilient state. It will integrate the climate change responsive plan with mainstream planning.

While developing the indicators for integrated multidimensional planning model the followings aspects are considered:

- to assess a system's resilience for both rural and urban ecosystems.
- to understand dynamics of social–ecological systems in the light of resilience

5.1 Conceptualization of Integrated multidimensional planning model

While working on concept of integrated multidimensional model following aspects are taken into consideration:

- Mapping of multidisciplinary data sources;
- Reviewing the literature and categorizing the selected data;
- Identifying and naming the concepts;
- Integrating the concepts;
- Validating the conceptual framework.

The entire concept of integrated multidimensional model consists of basic four components:

(A) Vulnerability Assessment Index (VAI): It is a dynamic concept, significant to assess degree of present resilience of an area and to forecast future risks and vulnerabilities. The index analyzes and identifies characteristics of climate change hazards, its intensity, scope and impact on demography, infrastructure and other aspects of urban ecology. This concept deals with the affects of hazards, risks and uncertainties influencing various rural and urban population. VAI matrix is composed of three components, namely, demographic vulnerability, urban space informality and spatial dimension vulnerability. Urban space informality is applicable to urban areas only.

(B) Planning Initiatives: Any rural or urban area becomes more resilient when its governance is capable to promptly restore basic services and recommence social, institutional and economic activity after any hazard events. A common believe is that a more resilient State undertakes decision making processes in the realm of planning, open dialog, accountability, and collaboration. In this process rural and urban dwellers, local stakeholders, various social groups, communities, civil society, grassroots organizations, etc. participate. While weak governance lacks the capacity and capability to include participatory planning and decision making and generally fails to meet the challenges of resilience as well as increase the vulnerability of the urban population.

The role of governance in resiliency is very crucial, related to measures of quality of life, environmental well being, economic vitality and implementation of policies. Local authorities have important role in mitigation and adaption of climate change. According to this concept in order to cope with uncertainties, risks and hazards that cities and their communities may face, and make them more resilient, there needs a shift in governance. This shift will make governance more integrative, deliberative, and socially and eco-economically sound. This concept is comprises the components like implementation, monitoring and management.

(C) Plan for Prevention: In order to move towards greater resiliency and less vulnerability, rural and urban areas are required to prevent environmental hazards and climate change impacts. There are three main components that aim to prevent future catastrophes. These components assess mitigation policies to reduce hazards, include the spatial restructuring as a preventive measure for future environmental disaster, and search for alternative clean energy.

(D) Plan to Address Uncertainty: According to this concept the planning exercise should be uncertainty oriented rather than adapting the conventional planning approaches. There is a need to rethink and revise current planning methods which leads to address uncertainties, challenge the concepts, procedures, and scope of traditional planning approaches. Planning efforts should be towards controlling uncertainty either by taking action now to secure the future or by arranging actions to be taken in case an event occurs any time in future. In this concept there are three interrelated components, adaptation , spatial planning and sustainable urban design (for city planning only).

6 CONCLUSION

Climate change is no longer a distant possibility but a current reality (Work Bank -2009). There is no scope to disagree with the fact that the global climate change is an outcome of human-induced GHG emissions. Increased levels of heat trapped in the atmosphere have accelerate the process of modifying weather patterns, which in turn alter temperatures, sea levels, storm frequencies, etc. These will impact both urban and rural areas especially those are in geographically sensitive areas.

Sustainable development, climate change impacts and disaster risk management issues are core concerns for each and every nation. The action plan to reduce the impact of climate change starts with reducing emission of GHG. But reducing GHG emissions is not the sole solution to combat climate change. Management of urban areas, their growth and spatial planning requires the consideration of disaster risk management and the climate change agenda as essential components of urban development plan. Expectations from rural planning encompasses plan for extreme events , such as storms , flood and plan to secure agricultural productivity.

Scope of SDG13 includes multi-dimensional focus for adaptation and mitigation, mainstreaming climate concerns in development policies and discussing financial mechanisms to meet the targets. The proposed integrated multidimensional model for climate change responsive planning is multidimensional in nature, it comprises components like vulnerability assessment, plan for prevention , plan for uncertainty and planning initiatives for successful implementation of model. The Model has ample scope to achieve targets SDG13.

While comparing outcome of each component of integrated multidimensional model with targets of SDG 13 it appears that targets of SGD 13.1, 13.3, 13.3b are directly addressed by components like ; Vulnerability assessment index, Plan for prevention and Plan to address uncertainty, while SDG 13.2 and 13.3a targets can be achieved through meaningful planning initiatives.

Vulnerability of any geographical location is not static rather it is a function of exposure, sensitivity and adaptive capacity. The proposed model is a dynamic concept varies with geographical location, nature of impact of climate change , level of exposure, sensitivity and adaptive capacity . Plan for combating climate change may not be considered as stand-alone effort it should be embedded with exiting city and rural planning programmes, schemes. The proposed integrated multidimensional planning model for climate change responsive planning can be easily merged with the exiting rural and city planning schemes of India for achieving targets of SDG 13.

(Prof. Dr.-Ing. Detlef Kurth, TU Kaiserslautern, Pfaffenbergstraße 95, 67663 Kaiserslautern, detlef.kurth@ru.uni-kl.de)

1 ABSTRACT

Der Kampf gegen den Klimawandel wird zunehmend zu einer Aufgabe der Stadtplanung. Klimaneutrale Gebäude reichen nicht aus – die Klimaneutralität muss ebenso auf der Ebene des Stadtquartiers erreicht werden. Dafür sind Stadtentwicklungskonzepte mit Energiekonzepten zu kombinieren, mit Aussagen zur dezentralen Gewinnung sowie zur Verteilung und Speicherung von erneuerbaren Energien. Der Fokus dieses Papers liegt auf der Wärmeversorgung von Stadtquartieren; die Mobilität sowie die Stromversorgung werden nicht betrachtet.

Die ökologische und technische Effizienz von wärmeeffizienten urbanen Systemen erfordert eine kompakte und dichte städtebauliche Struktur. Dabei sind die vielseitigen Zusammenhänge und Wechselwirkungen zwischen Nutzern, Gebäuden, technischer Infrastruktur und der Umwelt zu berücksichtigen. Mit dem Prozess der „Energieleitplanung“ kann diese enge interdisziplinäre Zusammenarbeit gesteuert werden. Dieses Vorgehen gewährleistet, dass neue oder optimierte technische Systeme frühzeitig im Planungsprozess berücksichtigt werden. In der Energieleitplanung müssen inhaltliche Ziele und Indikatoren formuliert werden, wie die energetischen Vorgaben mit den Instrumenten der Stadtplanung umgesetzt werden können. Die Stadtplanung übernimmt dabei eine Koordinationsfunktion für andere Disziplinen,um die energetisch optimierte Planung in einem iterativen Prozess zu steuern.

Im Rahmen des Forschungsprojeks „Integrative Betrachtung einer nachhaltigen Wärmebewirtschaftung von Stadtquartieren im Stadtentwicklungsprozess“ (IWAES), gefördert vom Bundesministerium für Bildung und Forschung (BMBF), wird analysiert, wie ein ausgeglichener Wärme- und Kältehaushalt auf Quartiersebene hergestellt werden kann. Dies soll anhand der „Sowieso-Infrastruktur“ erreicht werden, hier mit einem thermisch aktivierten Hybridkanal. Neben seiner primären Funktion der Abwasserentsorgung soll der Kanal auch Abwärme und Abkälte im Stadtquartier transportieren. Hierfür muss der thermisch aktivierte Hybridkanal im Verteilungs-, Entzugs- und Einspeichermodus operieren können. Restbedarfe sollen durch im Quartier generierte erneuerbare Energien gedeckt werden, z.B. Solar- und Geothermie oder Photovoltaik.

Als Untersuchungsgebiet dient das Bahnkonversionsprojekt Rosenstein in Stuttgart (ehemals „Stuttgart 21“). Das städtebauliche Konzept der Stadt Stuttgart ist hinsichtlich der „Wärmedichte“, die sich unter anderem aus der baulichen Dichte und Kompaktheit ergibt, zu überprüfen und ggf. anzupassen.Stadtplaner, Bauingenieure und Energieingenieure arbeiten im Projekt eng mit kommunalen Vertretern sowie privatwirtschaftlichen Unternehmen zusammen. Neben den technischen Details des Hybridkanals und des Verteilsystems werden somit auch Schnittstellen zwischen den Disziplinen definiert, um den Prozess der Energieleitplanung weiterzuentwickeln.

Keywords: Wärme- und Kältenetz, Abwärmenutzung, Energiegerechte Stadtentwicklung, Energieleitplanung, thermisch aktivierter Hybridkanal

2 EINLEITUNG

In Deutschland gibt es insgesamt rund 21,7 Mio. Gebäude (dena 2019: 6), davon sind 19 Mio. Wohngebäude (dena 2019: 10), etwa 15,75 Mio von den Wohngebäuden sind Ein- und Zweifamilienhäuser (ebd.). 2,7 Mio. Gebäude sind Nichtwohngebäude, ihr Anteil am Gebäudeendenergieverbrauch beträgt aber überproportional 36 % (dena 2019: 14).64 % des Gebäudeenergieverbrauchsentfallen auf Wohngebäude (dena 2019: 10).

Für Ein-und Zweifamilienhäuser existieren bereits viele Konzepte zur autarken Energieversorgung, sowohl für Neubau als auch für Bestandsgebäude. Diese umfassen in der Regel die Nutzung von Umgebungsluft oder Solarthermie, Photovoltaik und Geothermie, in Verbindung mit Energiespeicherlösungen sowie Dämmungen etc. „Ein-und Zweifamilienhäuser […] haben im Vergleich zu Mehrfamilienhäusern […] große Wohnflächen je Wohneinheit und hohe quadratmeterbezogene Energieverbräuche.“ (dena 2019:10). Zugleich ist die Fläche, die zur Energiegewinnung zur Verfügung steht,im Verhältnis zumEnergieverbrauch gut. Hier gilt es,vor allem die jährliche Sanierungsrate von derzeit 1% zu erhöhen (dena 2019: 7).

Die Herausforderung besteht aber darin, integrierte Konzepte für Stadtquartiere mit hohen Bau- und Bevölkerungsdichten zu entwickeln. Hier stehtin der Regel wenig Dach- und Freifläche pro Bewohner zur Verfügung, um erneuerbare Energien zu gewinnen. Erschwert werden die Bestrebungen zusätzlich durchdiverse Nutzungskonflikte, z.B. hinsichtlich Verschattung, Dachbegrünungen, Blendung und Spiegelung, Brandschutz etc.

In diesem Beitrag wird aufgezeigt,wieWärmeenergiegewinnung und -versorgung auf Stadtquartiersebene durch dieEnergieleitplanunggesteuert werden können. Dazu gehören die interdisziplinäre Zusammenarbeit, die Integration unterschiedlicherPlanungsinstrumente sowie ein System zur technischen Umsetzung.

3 INTEGRIERTER PLANUNGSANSATZ FÜR DIE QUARTIERS-WÄRMEVERSORGUNG

Gebaute Strukturen sind beständig, eine nachträgliche Änderung der Baustruktur oder Versorgungsinfrastruktur ist sehr kostspielig und schwer umsetzbar.Der integrierte Planungsansatz dient dazu, frühzeitig alle relevanten Belange bei der Planung zu berücksichtigen.Dennoch können technische Systeme sehr anpassungsfähig sein, die Stadt- und Gebäudetechnik wird kontinuierlich erneuert. Anpassungsfähigkeit und Technologieoffenheit sind somit zentrale Kriterien im Städtebau.

Die Erforderlichkeit von Klimaschutzkonzepten ergibt sich auch aus der BauGB-Novelle 2011, in der gemäß § 1 Abs. 5 und 6 Nr. 7a BauGB die Abwägungsbelange bezüglich des Klimaschutzes definiert werden. Es gibt bislang aber wenige Reglungen, wie entsprechende Konzepte zu gestalten sind, und wie die verschiedenen Disziplinien bei der Planung der Wärmeversorgung von Stadtquartieren kooperieren können. In der Stadtplanung sind „[b]ei der Aufstellung der Bauleitpläne […] die öffentlichen und privaten Belange gegeneinander und untereinander gerecht abzuwägen.“ (§ 1 Abs. 7 BauGB).Zusätzlich wird durch die Vorschriften zur Beteiligung bei der Planung nach §§ 3 und 4 BauGB sichergestellt, dass die Öffentlichkeit, Behörden und sonstige Träger öffentlicher Belange frühzeitig in die Planung einbezogen werden.Andere Fachdisziplinen werden nicht explizit genannt.

Außerdem sollen für jede Stadt und jeden Stadterneuerungsschwerpunkt integrierte Stadtentwicklungskonzepte erstellt werden. Die Rahmenbedingungen für die nachhaltige Stadtentwicklung sind in der Leipzig Charta und in der Nationalen Stadtentwicklungspolitik definiert: gemeinwohlorientiert, kompakt, nutzungsgemischt, sozial ausgeglichen und autoarm. Stadtentwicklungskonzepte bieten die Möglichkeit, vor der formellen Bauleitplanung Zukunftsstrategien zu erarbeiten, mit einem sehr partizipativen und integrierten Ansatz. Hier können bereits frühzeitig Ziele zum Klimaschutz berücksichtigt werden, in dem z. B. künftige Reduktionsziele für die Stadtentwicklung mit kalkuliert werden. Gemäß Baugesetzbuch sind "[…] sonstige städtebauliche Planungen[…]" (§ 1 Abs. 6 Nr. 11 BauGB) als abwägungsrelevante Grundlage in den Planungsprozess einzubeziehen. Diese Konzepte sollten als Teil einer gesamtstädtischen Stadtentwicklungsplanung einen räumlich-funktionellen Bezug aufweisen und durch die Gemeinde förmlich beschlossen werden.

In den Bauleitplänen (Flächennutzungsplan/Bebauungsplan)wird die Gestaltung und Nutzung von Stadtquartieren festgelegt. Die energierelevanten Steuerungsmöglichkeiten werden in Abschnitt 5 dargestellt.

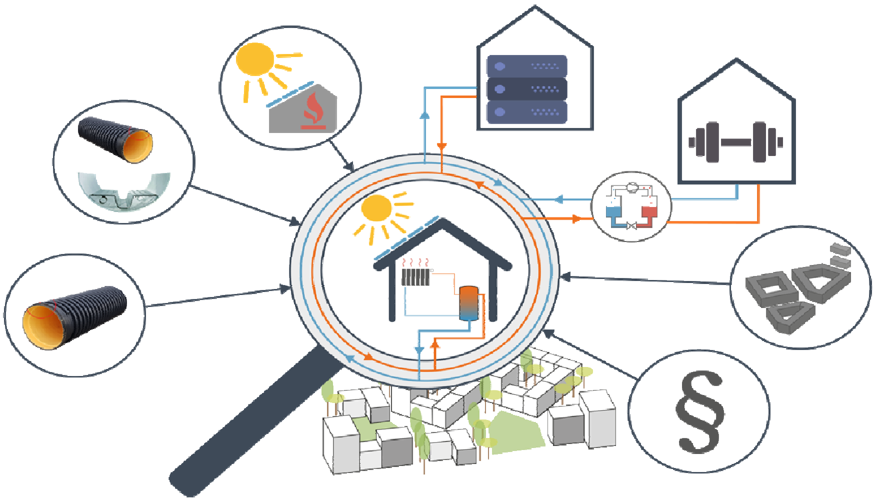

Fig. 1: Integration verschiedener Komponenten bei der Wärmeversorgung von Stadtquartieren.

Bei der Wärmeversorgung von Stadtquartieren variieren die zu beteiligenden Disziplinen,abhängig vom Versorgungssystem. Die unterschiedlichen Systeme müssen frühzeitig anhand der spezifischen Rahmenbedingungen jedes Quartiers ermittelt werden. Hierfür ist es unerlässlich, alle potenziell relevanten Akteure einzubinden. Neben der Stadtplanung sind das unter anderem Energieingenieure, Bauingenieure und Architekten.

In der Regel beginnen diese Disziplinien ihre Arbeit erst auf Grundlage der bestehendenstädtebaulichen Planung,sie müssen die Vorgaben aus der Bauleitplanungumsetzen. Im Städtebau wurden bereits teilweise Zwangspunkte geschaffen, die ggf. energetisch suboptimal sind.Die Fachdisziplinen sollten deshalb früher in den Planungsprozess einbezogen werden, damit Quartiere in einem iterativen Prozess durch Abstimmungen verschiedener Kriterien energieoptimiert geplant werden können. Dieser Prozess ist durch die Stadtplanung zu koordineren, da auch die energetischen Belange in die Abwägung nach § 1 Abs. 7 BauGB eingestellt werden müssen.

4 UNTERSCHIEDLICHE HANDLUNGSANSÄTZE BEI ENERGIEKONZEPTEN

Für die interdisziplinäre Zusammenarbeit auf der Verwaltungs-, Planungs- und Umsetzungsebene sind ein einheitliches Begriffsverständnis und ein gemeinsames Planungsinstrumentarium erforderlich.Bei der nachhaltigen Energieversorgung auf Quartiersebene gibt es unterschiedliche Herangehensweisen, die oft nicht einheitlich definiert sind. Hierzu zählen z. B. (kommunale/integrierte) Energiekonzepte, Energieleitplanung, Energienutzungsplanung, Energieplanung oder Energiepläne, kommunale Energieversorgungskonzepte, energetische Quartierskonzepte und andere. Auf sektoraler Ebene kommen weitere Instrumente hinzu. Im Baugesetzbuch werden zu dieser Thematik keineBezeichnungenangewendet.

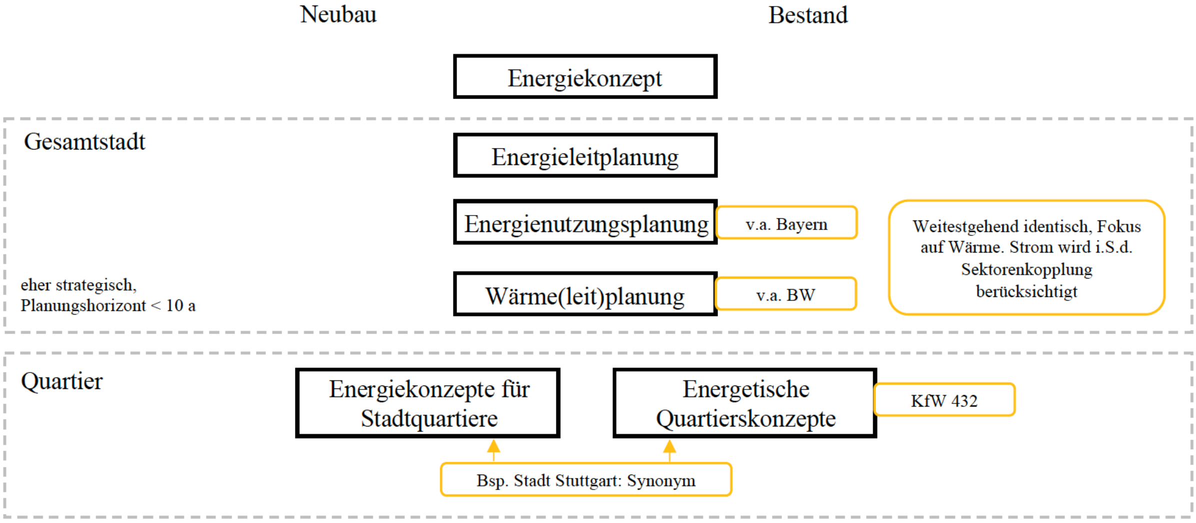

Fig. 2: Auswahl von Instrumenten der energetischen Planung

Häufig werden die Begriffe als Synonyme ohne klare Abgrenzung zueinander verwendet. Teilweise werden weder die Bezugsebenen noch die Akteursstrukturen oder Planungsvorgänge unterschieden. Auch die Inhalte, die die einzelnen Instrumente umfassen, sind oft nicht direkt nachvollziehbar. Sie unterscheiden sich hauptsächlich in ihrer räumlichen Maßstabsebene, ihrer Bindungswirkung, ihrem inhaltlichen Bezug (Energie, Strom und/oder Wärme), den Zielgruppen, dem Detaillierungsgrad und der Datenbasis.

Beeinflusst wird der Prozess darüber hinaus durch vielseitige Faktoren wie beispielsweise Bestandsplanung oder Neubau, die Versorgungsstrukturen, die Eigentümerstrukturen und dieAnzahl und Motivation der Bauherren, sofern diese bereits bekannt sind. Auch die finanzielle Ausstattung sowie die Innovationsaffinität der Kommunen sind bestimmende Faktoren.

Mit diesen Instrumenten wird das Ziel verfolgt, die Trias Energieerzeugung, -verteilung und -verbrauch zu analysieren und zu optimieren. Die unterschiedlichen Herangehensweisen sorgen jedoch für Missverständnisse zwischen den Beteiligten. Die interdisziplinäre Zusammenarbeit zwischen Stadtplanern, Architekten, Bauingenieuren, Energieingenieuren, Facility Managern und vielen anderen ist jedoch die Grundlage für eine optimale Energieversorgung auf Quartiersebene und auch für die Gesamtstadt.

Wir begreifen das Modell der Energieleitplanung als einen prozesshaften Ansatz. Bislang aufgestellte Energieleitpläne sind informeller Natur, ebenso die Energienutzungspläne. Für ein neues, eigenständiges formelles Instrument im Sinne eines„Energieleitplans“ gibt es bislang keine rechtliche Grundlage, aber diverse Förderprogramme. Auch sind die Wechselwirkungen mit weiteren Ressourcen zu berücksichtigen. Der Instrumentenkasten der Stadtplanung bietet bereits zahlreiche Möglichkeiten, die Energieleitplanung zu implementieren. Diese Möglichkeiten werden in Abschnitt 5 aufgezeigt.

Die verschiedenen Quartiere innerhalb einer Gesamtstadt unterscheiden sich häufig deutlich,unter anderem bezüglich der Bauweise bzw. Kompaktheit, Baustoffe, Sanierungszustand, Anzahl und Charakteristika der Bewohner, der Flächengröße und -effizienz sowie der vorhandenen Nutzungen. Von daher sollte die Analyse des Ist-Zustands sowie die Erstellung eines Energieleitplans auf Quartiersebene durchgeführt werden, immer in Verbindung mit Stadtteilkonzepten.

5 STEUERUNGSINSTRUMENTE DER ENERGIELEITPLANUNG

Das deutsche Planungssystem folgt der Normenhierarchie und wird stufenweise auf verschiedenen Ebenen gegliedert. Auf Bundesebene werden z.B. im Raumordnungsgesetz grundsätzliche Entscheidungen getroffen und Leitlinien formuliert. Viele der energierelevanten rechtlichen Vorgaben auf Bundesebene resultieren aus der Implementierung europäischer Vorgaben in nationales Recht.

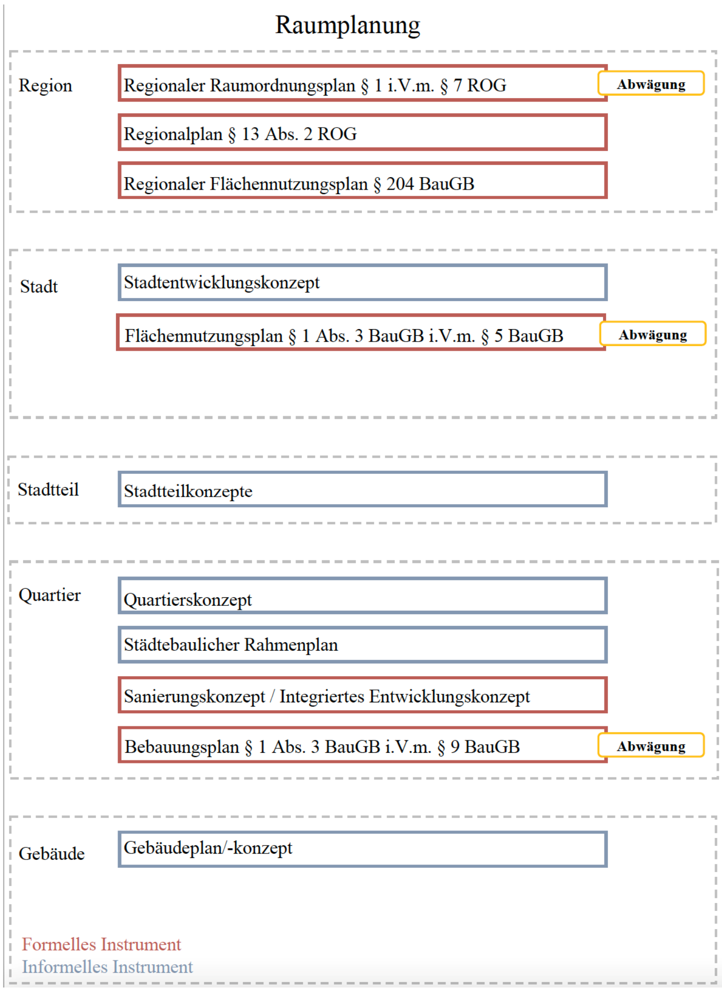

Fig. 3:Steuerungsinstrumente der Raumplanung

5.1 Raumordnungsplanung

Gemäß § 1 Abs. 1 und 3 ROG ist es die Aufgabe der Raumordnung, den Gesamtraum der BRD und ihrer Teilräume durch raumordnerische Zusammenarbeit zu entwickeln, zu ordnen und zu sichern. Gemäß § 2 Abs. 2 Nr. 6 ROG ist „[d]en räumlichen Erfordernissen des Klimaschutzes […] Rechnung zu tragen“. Energetisch sinnvolle Abgrenzungen von Räumen entsprechen u.U. keinen administrativen, geographischen oder anders gegliederten Gebieten. Von daher muss die Regionalplanung über die Grenzen hinaus agieren.

Diesem Umstand trägt § 1 Abs. 1 S. 1 ROG Rechnung: „Der Gesamtraum der Bundesrepublik Deutschland und seine Teilräume sind durch Raumordnungspläne, durch raumordnerische Zusammenarbeit und durch Abstimmung raumbedeutsamer Planungen und Maßnahmen zu entwickeln, zu ordnen und zu sichern."

Auf Ebene der Länder sind sowohl ein Raumordnungsplan für das Landesgebiet (landesweiter Raumordnungsplan) und Raumordnungspläne für Teilräume der Länder (Regionalpläne) aufzustellen (§ 13 Abs. 1 ROG). Die in Regional- oder Landesentwicklungsplänen enthaltenen Aussagen sind in der Regel generalisiert, enthalten aber wichtige Aussagen unter anderem zur Siedlungsentwicklung, Freiraumstruktur und Infrastruktur, und somit auch zu großflächigen Anlagen für die Strom- und Wärmeerzeugung. Der Energiebedarf kann meist nicht auf Quartiersebeneoder auf Stadtebene gedeckt werden. Durch Windenergieanlagen, Wasserkraft oder auch großflächige Geothermie-, Agrothermie- oder Photovoltaikanlagen im Umland kann der Restbedarf potenziell gedeckt werden. „Bei der Aufstellung der Raumordnungspläne sind die öffentlichen und privaten Belange […] gegeneinander und untereinander abzuwägen" (§ 7 Abs. 2 ROG), um die Nutzungen bereits frühzeitig optimal zu steuern.

5.2 Bauleitplanung

Nach § 1 Abs. 4 BauGB sind „[d]ie Bauleitpläne […] den Zielen der Raumordnung anzupassen." So wird sichergestellt, dass die Ergebnisse der Raumordnungsplanung in der weiteren Planung konkretisiert und umgesetzt werden. „[D]ie Nutzung erneuerbarer Energien sowie die sparsame und effiziente Nutzung von Energie" sind bei der Aufstellung von Bauleitplänen besonders zu berücksichtigen (§ 1 Abs. 6 Nr. 7 lit. f BauGB). Zusätzlich soll „[…] den Erfordernissen des Klimaschutzes […] durch Maßnahmen, die dem Klimawandel entgegenwirken […] Rechnung getragen werden." (§ 1 Abs. 4 BauGB)

Bei der Ausweisung der zukünftig bebaubaren Flächen im Flächennutzungsplan können bereits energetisch optimierte Bedingungen berücksichtigt werden. Bei einer ausgeprägten Topographie kann z.B. die natürliche Verschattung genutzt werden, um den Kühlbedarf im Sommer zu reduzieren. Darüber hinaus können Nutzungen nach § 1 Abs. 1 BauNVO so miteinander verknüpft werden, dass Synergien entstehen.

Durch § 5 Abs. 2 Nr. 2 lit. b BauGB wird die Darstellung der Ausstattung des Gemeindegebiets von „[…] Anlagen, Einrichtungen und sonstigen Maßnahmen [des Gemeindegebiets], die dem Klimawandel entgegenwirken," ermöglicht. Die Art der Anlagen werden nicht präzisiert (Battis u.a. 2019 Rn 17b). „Erfasst werden alle Anlagen, Einrichtungen und sonstigen Maßnahmen des Energiefachrechts, insbesondere des EEWärmeG sowie des KWKG." (ebd.)

Durch Festlegungsmöglichkeiten i.S.d. § 5 Abs. 2 BauGB i.V.m. § 16 Abs. 1 BauNVO können im Flächennutzungsplan darüber hinaus bereits die Geschossflächenzahl, die Baumassenzahl und die Höhe der baulichen Anlagen bestimmt werden.Diese Parameter haben wiederum Einfluss auf energierelevante Kriterien wie z.B. die Verschattung oder beheizte Nettogeschossfläche.

Aus Flächennutzungsplänen werden Bebauungspläne entwickelt (§ 8 Abs. 2 BauGB).Die Kommunen treffen nach den in § 9 Abs. 1 BauGB i.V.m. den in der BauNVO aufgezeigten Möglichkeiten rechtsverbindliche Festsetzungen für die städtebauliche Ordnung. Der Energiebedarf bzw. die Energieeffizienz im Quartier können über Festsetzungen hinsichtlich der Art und dem Maß der baulichen Nutzung (§ 9 Abs. 1 Nr. 1 BauGB) und der Bauweise, der überbaubaren und nicht überbaubaren Grundstücksflächen sowie der Stellung der baulichen Anlagen (§ 9 Abs. 1 Nr. 2 BauGB) gesteuert werden.

Nach § 16 Abs. 2 Nr. 1 bis 4 BauNVO kann das Maß der baulichen Nutzung „[…] durch Festsetzung der Grundflächenzahl oder der Größe der Grundflächen der baulichen Anlagen, der Geschossflächenzahl oder der Größe der Geschossflächen, der Baumassenzahl oder der Baumasse, der Zahl der Vollgeschosse, der höhe baulicher Anlagen" bestimmt werden.Diesbezügliche Festsetzungen wirken sich auf energetisch relevante Indikatoren wie Versiegelungsgrad, Verschattung, bauliche Dichte, Kompaktheit und das A/V-Verhältnis aus.

Zusätzlich sind die Regelungsmöglichkeiten des § 16 Abs. 4 BauNVO zentral für die Energieeffizienz von Neubauquartieren. Durch die Festlegung eines Mindestmaßes der „[…] Geschossflächenzahl oder [der] Größe der Geschossfläche, [der] Zahl der Vollgeschosse und [der] höhe baulicher Anlagen […]" (§ 16 Abs. 4 S. 1 BauNVO) kann die städtebauliche Dichte sowie die Kompaktheit der Gebäude gesteuert werden. Außerdem kann hierdurch ein schonender Umgang mit Grund und Boden gesteuert werden. Dies kann die Erhitzung von Stadtquartieren im Sommer reduzieren, was wiederum den Kühlbedarf der baulichen Anlagen

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

reduziert. Zudem wird dem in § 1a Abs. 3 S. 1 BauGB verankerten Grundsatz „[m]it Grund und Boden […] sparsam und schonend […]“ umzugehen, Rechnung getragen.

Außerdem kanndurch Bestimmungen zu Bauweise, Baugrenzen und Bautiefen unter anderem die Stellung der Baukörper gesteuert werden. Gemäß § 22 Abs. 1 BauNVO kann im Bebauungsplan „[…] die Bauweise als offene oder geschlossene Bauweise festgesetzt werden.“ Eine geschlossene Bauweise weist im Vergleich in der Regel einen geringeren Energieverlust auf.Zu berücksichtigen ist aber auch das A/V-Verhältnis, also die Kompaktheit der Baukörper, das zur Energieeffizienz beiträgt.

Durch Anwendung der § 9 Abs. 1 Nr. 12, 13 und 21 BauGB können Festsetzungen bezüglich Versorgungsflächen, -anlagen und -leitungen sowie den entsprechenden Geh-, Fahr- und Leitungsrechten getroffen werden.§ 9 Abs. 1 Nr. 23 lit. b BauGB regelt die Möglichkeiten zur Festlegung von Gebieten, in denen „[…] bei der Errichtung von Gebäuden oder bestimmten sonstigen baulichen Anlagen bestimmte bauliche und sonstige technische Maßnahmen für die Erzeugung, Nutzung oder Speicherung von Strom, Wärme oder Kälte aus erneuerbaren Energien oder Kraft-Wärme-Kopplung getroffen werden müssen“.

5.3 Weitere Instrumente

Zusätzlich zu den oben aufgeführten Regelungen kann die Gemeinde weitere Regelungen durch städtebauliche Verträge i.S.d. § 11 BauGB treffen. Städtebauliche Verträge werden eingesetzt, um Regelungen zwischen Privaten (z.B. Investoren) und der öffentlichen Hand abzuschließen. Es gibt verschiedene Arten der städtebaulichen Verträge wie z.B. Durchführungs- oder Kostenübernahmeverträge. § 11 Abs. 1 BauGB führt die Gegenstände an, die insbesondere Inhalt städtebaulicher Verträge sein können.

Gemäß § 11 Abs. 1 Nr. 4 BauGB kann die klimabezogene Infrastruktur (EZBK/Krautzberger 2020 Rn. 165), insbesondere „[…] die Errichtung und Nutzung von Anlagen und Einrichtungen zur dezentralen und zentralen Erzeugung, Verteilung, Nutzung oder Speicherung von Strom, Wärme oder Kälte aus erneuerbaren Energien oder Kraft-Wärme-Kopplung […]“ entsprechend den mit den städtebaulichen Planungen und Maßnahmen verfolgten Zielen und Zwecken Gegenstand eines städtebaulichen Vertrags sein.

Auf Grundlage der jeweiligen Gemeindeordnung kann auch ein Anschluss- und Benutzungszwang festgesetzt werden. Gemäß § 11 GemO BW kann die Gemeinde „[…] bei öffentlichem Bedürfnis durch Satzung für die Grundstücke ihres Gebiets den Anschluss an […] die Versorgung mit Nah- und Fernwärme […] vorschreiben.Wurden Regelungen bezüglich eines Anschluss- und Benutzungszwangs getroffen, bleiben diese von den in den städtebaulichen Verträgen getroffenen Vereinbarungen unberührt (EZBK/Krautzberger 2020 Rn. 165).

Nach § 11 Abs. 1 Nr. 5 BauGB können städtebauliche Verträge insbesondere Anforderungen an die energetische Qualität zum Gegenstand haben. Wie auch die städtebaulichen Verträge über o.g. klimabezogene Infrastruktur müssen die in den nach § 11 Abs. 1 Nr. 5 BauGB festgelegten Anforderungen den Zielen und Zwecken der städtebaulichen Planung und Maßnahmen entsprechen (§ 11 Abs. 1 Nr. 5 BauGB).

§ 12 BauGB regelt den Vorhaben- und Erschließungsplan (der Bestandteil des vorhabenbezogenen Bebauungsplans wird), der über die Vorgaben des § 9 BauGB hinaus Möglichkeiten bietet, Festsetzungen zum Klimaschutz bei städtebaulichen Planungen zu treffen. Der Vorhabenträger erstellt den Plan und stimmt ihn im Anschluss mit der Gemeinde ab. Der Durchführungsvertrag stellt die Grundlage der Durchführung des Bauleitplans dar (§ 12 Abs. 1 S. 1 BauGB). Auch Kaufverträge können einzelne klimaschutz- oder energierelevanten Aspekte beinhalten. Da bei Kaufverträgen unter anderem die Koppelungsverbote nicht greifen, können die hier vereinbarten Regelungen umfassender sein als die Regelungen in öffentlich-rechtlichen Verträgen.

Bei der integrierten Betrachtung einer nachhaltigen Wärme- und Kältebewirtschaftung sollten die Instrumente der verschiedenen Disziplinen auf allen Ebenen miteinander verknüpft werden. Zusätzlich ergänzen sich formelle und informelle Planungsinstrumente.

Im Schaubild "Energieleitplanung" werden die unterschiedlichen Handlungsebenen von der Region über die Gesamtstadt, den Stadtteil und das Quartier bis hin zur Gebäudeebene sowohl für die Planungsinstrumente als auch für die Energieversorgungskonzepte verdeutlicht. Die Planungsebenen der Stadtentwicklungsplanung und Bauleitplanung nach BauGB sollten mit denen der energetischen Fachpläne korrespondieren. So kann auf der Gesamtstadtebene der Wärmebedarf über standardisierte Gebietstypologien abgeschätzt werden, darauf aufbauend können detailliertere Energieversorgungskonzepte und Gebäudemodernisierungspotentiale formuliert werden. Diese Ergebnisse des Energieleitplans stellen dann die Grundlage für Darstellungen im Flächennutzungsplan dar, und sie können somit eine verwaltungsinterne Verbindlichkeit für die folgenden Stadtteilkonzepte und Bebauungspläne entfalten.

Die Energieleitpläne auf Quartiersebene enthalten Teilschritte von der Analyse über die Zielformulierung bis hin zu einem Maßnahmenkatalog und einer Umsetzungsstrategie. In ihnen können die gebietstypologischen Wärmebedarfe und Umbaupotenziale auf einer konkreteren Datenbasis als für die Gesamtstadt ermittelt werden. Sie sollten z.B. Aussagen zur Energieversorgung enthalten (Nah- oder Fernwärme, Photovoltaik- oder Solarthermieanlagen), zur energetischen Gebäudesanierung, aber auch zu städtebaulichen Aspekten wie Nachverdichtung, Wohnungsanpassung und zum Verkehr. Die Ergebnisse sollten dann in die Sanierungskonzepte oder ggf. Bebauungspläne implementiert werden.

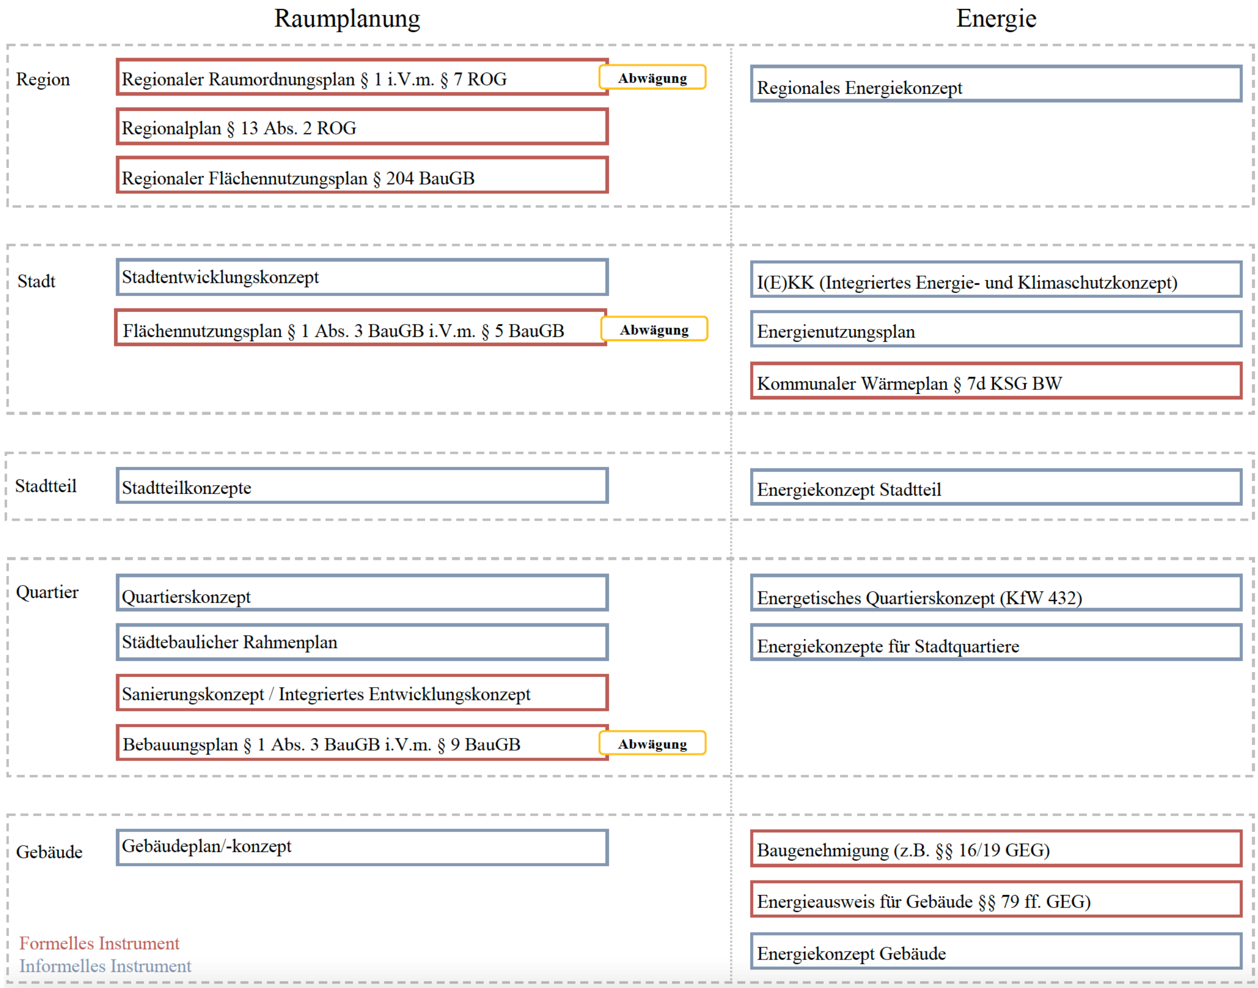

Fig. 4: Modell der Energieleitplanung

6 BEISPIELHAFTES WÄRMEVERSORGUNGSSYSTEM AUF QUARTIERSEBENE

Wie kann ein ganzjährlich ausgeglichener Wärme- und Kältehaushalt auf Quartiersebene hergestellt werden? Dieser Frage widmet sich das Forschungsprojekt am Beispiel des Rosensteinquartiers der Stadt Stuttgart. Das Versorgungssystem basiert auf Abwärme- und Abkältenutzung in nutzungsgemischten Quartieren. Die überschüssige Abwärme, die beispielsweise durch die Nutzung technischer Geräte wie Kühl- oder Gefrierschränken entsteht, kann der Luft entzogen und mithilfe eines Wärmetauschers an anderer Stelle im Quartier zu Kühlzwecken zur Verfügung gestellt werden.

Der Siegerentwurf des städtebaulichen Wettbewerbs von asp Architekten GmbH dient als Grundlage für die Entwicklung des Versorgungssystems.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Fig. 5: Siegerentwurf, Internationaler Wettbewerb Rosensteinquartier Stuttgart

Fig.5 verdeutlicht, dass demäß dem städtebaulichen Entwurf ein durchgrüntes Stadtquartier entstehen soll. Entsprechend den Forderungen der Leipzig Charta soll ein durchmischtes, möglichst autofreies Quartier mit einer qualitätvollen Dichte und ansprechenden öffentlichen Räumen entstehen. Quartiershubs dienen dazu, diverse Infrastruktureinrichtungen zu bündeln.

Die Abwärme und Abkälte soll mithife der „Sowieso-Infrastruktur", in diesem Fall einem thermisch aktivierten Hybridkanal, im Quartier transportiert werden. Zusätzlich fungiert er als Energiesenke. Durch die Mehrfachnutzung einer Infrastruktur können Synergien geschaffen und der Ressourcenverbrauch reduziert werden. Das System setzt eine noch zu bestimmende Wärmedichte voraus, um einen hohen Wirkungsgrad zu erreichen. Der thermische Ausgleich im Untersuchungsgebiet soll stufenweise erfolgen (siehe Fig. 6).

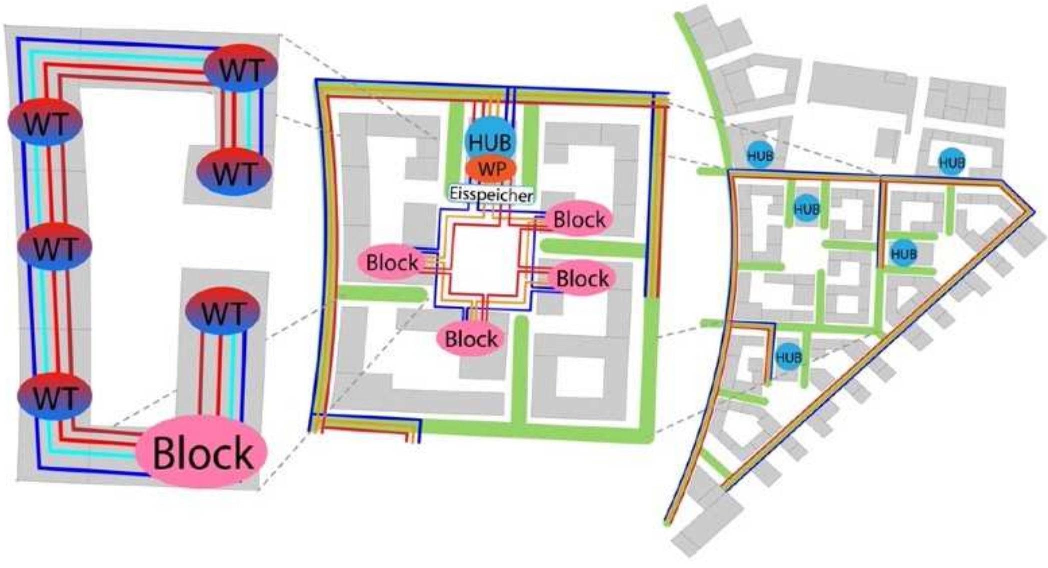

Fig. 6: Dreistufiger Ausgleich des Wärmebedarfs auf Quartiersebene mithilfe eines thermischen Hybridkanals

Zuerst werden die Bedarfe innerhalb eines Gebäudes bzw. Gebäudeblocks ausgeglichen, die Gebäude(blocks) werden mit Wärmetauschern ausgestattet. Im nächsten Schritt wird der Bedarf in einem sogenannten „Hub-Areal" ausgeglichen. Hier werden die Gebäude durch einen Hub ergänzt, der neben

Quartiersgaragen undweiteren Infrastruktureinrichtungen auch Flächen für die Energieversorgung vorsieht. Hier können Energiespeicher sowie Wärmepumpen untergebracht werden. Die letzte Ausgleichsebene stellt das gesamte Quartier dar.(Weitere Informationen zum Forschungsprojekt: www.iwaes.de)

In diesem System werden die Stadtplanung und die Energieplanung durch die Disziplin der Siedlungswasserwirtschaft ergänzt, es werden also Instrumente der Entwässerung mit denen der Stadtplanung verknüpft.

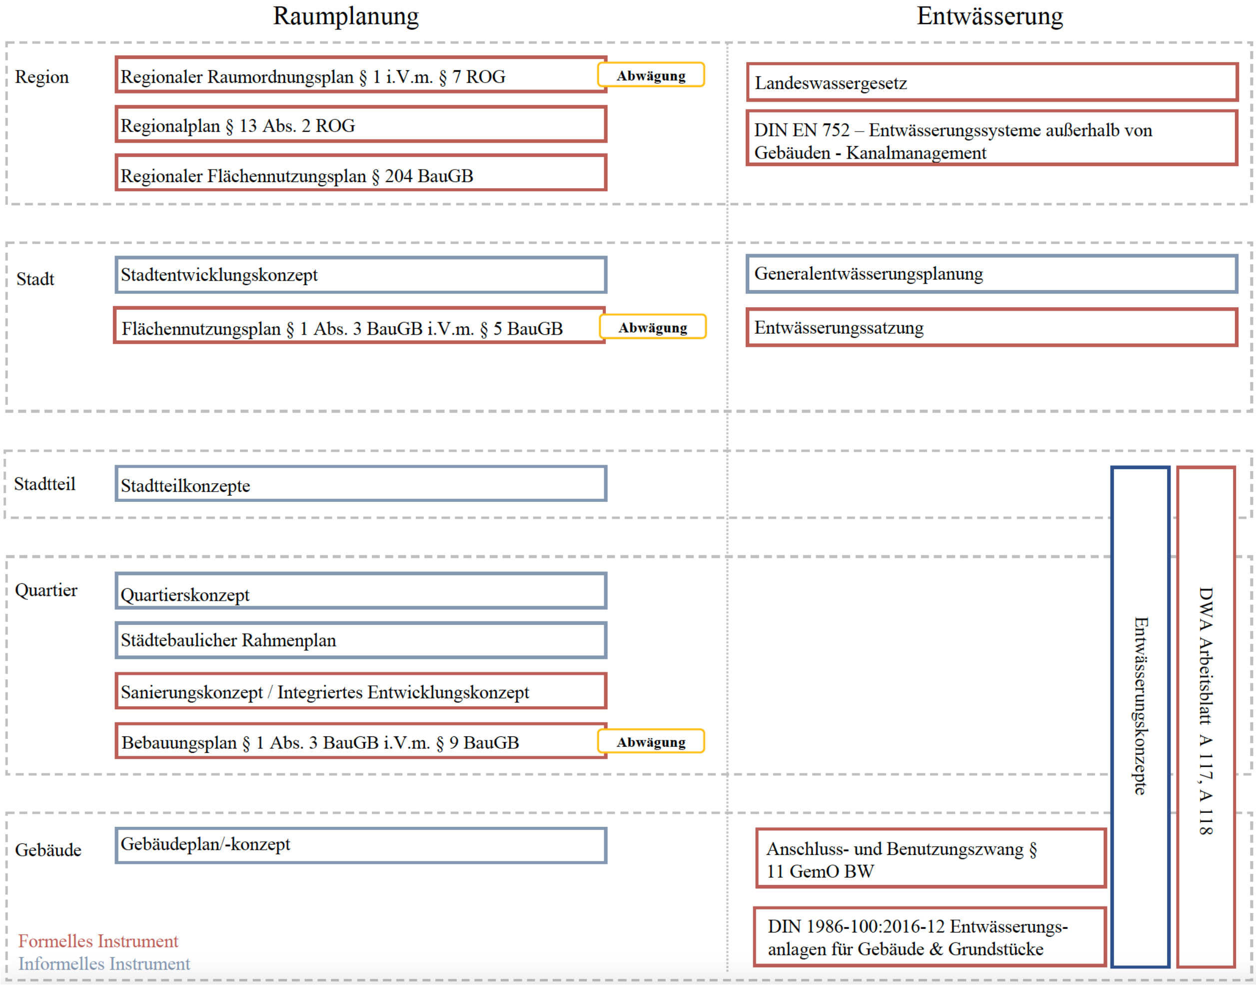

Fig. 7: Erweitertes Modell der Energieleitplanung

Andere Versorgungssysteme setzen voraus, dass Instrumente weiterer Disziplinen mit dem Instrumentenkasten der Stadtplanung verknüpft werden. Nur so kann sichergestellt werden, dass alle Belange in die Abwägung eingestellt werden können.

7 FAZIT

Die Wärmeversorgung bietet ein enormes Einsparpotenzial von Treibhausgasen. Um die Klimaziele zu erreichen, muss der Klimaschutz einen noch höheren Stellenwert bei der Planung einnehmen, insbesondere auf Quartiersebene. Das Planungsrecht umfasst bereits viele Instrumente, um die energiegerechte Planung zu gewährleisten. Der bestehende Instrumentenkasten könnte durch ergänzende Vorgaben optimiert werden.

Im Bereich der energetischen Planung gibt es sehr unterschiedliche Herangehensweisen und Begriffverständnisse. Für die interdisziplinäre Zusammenarbeit ist ein einheitliches, koordiniertes Planungsinstrument erforderlich. Das Forschungsprojekt möchteeinen Beitrag dazu leisten, Begriffsdefinitionen in Leitfäden oder Normen zu typisieren bzw. standardisieren.

Die Energieleitplanung ist vor allem als Modell und Prozessansatz zu betrachten. Die Energiewende bringt immer wieder technische Neuerungen mit sich, die eine veränderte, integrative Zusammenarbeit vieler Disziplinen erfordert. Das im Forschungsprojekt IWAES entwickelte Versorgungssystem veranschaulicht die Potenziale, die sich durch eine neue Kombination bestehender Technik ergeben. Die Energieleitplanung

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

muss immer wieder flexibel aufdie individuellen Gegebenheiten in den unterschiedlichen Quartieren und den Akteurskonstellationenreagieren. Die hier vorgestellte entwickelte Methodik legt einen Grundstein für die interdisziplinären Zusammenarbeit und die Integration der Wärmeversorgung in das Planungsrecht. Ausgehend von der Planungssystematik der Stadtentwicklung kann die Methode bedarfsgerecht weiterentwickelt werden.

Aufgrund des sehr komplexen deutschen Planungsrechts kann die Methode nicht ohne Weiteres auf die Planungssysteme anderer Länder angewendet werden. Da die Disziplinen Raumplanung, Energie und Wasserbau die Infrastrukturplanung weltweit beeinflussen, lässt sie sich jedoch individuell auf diverse Planungssysteme anpassen.

1 ABSTRACT

Within the SUGI initiative addressing the challenges of sustainable urban food, water and energy nexus (FWE-Nexus) the ongoing project SUNEX -funded by JPI Urban Europe in collaboration with the Belmont forum- is developing an integrated interdisciplinary approach to analyse the intersection between FWE-systems. It aims at supporting cities' decision-making process in formulating inclusive and sustainable urban FWE–strategies. The project has established an integrated modelling framework to model FWE demand and supply and assess their key intersections through a nexus approach that endorses sustainable and efficient solutions to cover cities FWE-demand. The modelling framework is being applied in 4 case studies for the cities Berlin, Bristol, Doha and Vienna. The applied Nexus-approach relies on profound urban FWE-data and consistent socio-economic and technological development scenarios constructed within a co-creation process supported by cities' stakeholder dialogue (Hainoun and Loibl, 2019). To address the complex interlinkages between the three systems and capture their key synergies, SUNEX has developed a novel concept called "Key Nexus Indicators (KINs)" that helps to quantify and monitor the key nexus-effects of urban FWE systems. The introduced KNIs are classified into two categories, addressing either dual effects (FW, FE, EW) or triple effects referring jointly to the 3 FWE systems. Altogether 6 triple KNIs and 22 dual KNIs of FWE-Nexus effects have been specified. The introduced KNIs are quantified based on the results of the developed future FWE demand-supply scenarios formulated using the established SUNEX-modelling framework. The scenario results are monitored and evaluated to specify the strength of coupling effects (nexus-grade) using the introduced KNIs.

Keywords: sustainable urban development, food-water-energy-nexus, Key nexus indicator, city decision making , SUNEX project

2 METHODOLOGY

The urban FWE-Nexus approach applied within SUNEX project focuses on analysing the intersection between the three systems along the supply chain of the considered urban area. For this purpose, an integrated demand-supply analysis of the FWE systems has been conducted using the newly established SUNEX-IMFA (Integrated Modelling Framework). In these Analyses sustainable FWE strategies for the considered demo cities has been formulated following expected future socio-economic and technological development aligned to the official cities' future visons (like SCWFS for Vienna) (Hainoun and Loibl, 2021). Due to the central role of the energy demand for the FWE-Nexus detailed modelling of the city's energy demand by sector and energy form (within SUNEX-IMFA) has been conducted using the end-use, bottom-up approach of the sub-module MAED-City. MAED-City concept disaggregates the urban energy demand by sector of consumption comprising building (household and service), agriculture, construction, manufacturing industry and transportation (passenger and freight). The future development by sector and fuel is projected following a sustainable, efficient and low-carbon transformation path. The employed drivers of the conceived transformation comprise energy efficiency improvement, switching to clean fuel, digitalisation and electrification. Considering the decarbonisation of electricity through increased renewable energy shares, the electrification accounts for increased penetration of electricity in the end-use of all consumption sectors like EV and H2 for passenger and freight transport, electrisation of building heat demand via heat pumps for space and water heating, etc. The energy supply accounts also for the increased need of flexibilization like P2H and P2G. However, the impact of sector coupling related to V2X is not considered within SUNEX-project. This is part of follow-up activities and other running projects. More detailed elaboration on the supply strategy for the case of Vienna city can be found by Horak and Hainoun (Horak et al., 2021).

Following an integrated demand-supply analysis an interdisciplinary approach is being applied aiming to quantify and optimise existing synergies between the three systems and thus supporting the desired sustainable urban transformation towards efficient, sustainable and low-carbon economy. Form the conceptual viewpoint the FWE-interlinkage is obvious, and the main related Nexus-Effects can be reasonably well defined. However, the quantitative analysis is challenging, in particularly for cities and urban areas with their strict geographic boundaries at which the considered FWE are balanced. Hence, many of the supply related effects lie fully or partially outside the boundaries of the cities on which the urban decision has no direct influence, e.g., the production and transport of food from long distances. However, cities -with their concentrated social and economic activities and intensive resources use- have their role to play in enabling the desired CC mitigation with focus on ensuring sustainable production and consumption pattern and working towards sustainable, resource-efficient and low-carbon economy where the expected growth is driven by the interaction between rapid technological innovation, sustainable infrastructure investment, and increased resource productivity (NCE, 2018). Moreover, the desired sustainable development needs to be balanced and inclusive resulting in efficient, liveable cities characterised by low-carbon, smart and resilient infrastructure. In this context the FWE-Nexus can provide a valuable contribution by harnessing existing synergies and making the intersection between the three systems impactful through innovative socio-economic and technological measures that focus on resource efficient practices like reducing food wastes and switching to renewable energy sources.

To quantify and monitor these interlinkages of FWE-systems, SUNEX has introduce the concept of “Key Nexus Indicators (KINs)”. Two categories are identified addressing either dual effects among the three systems (FW, FE, EW) or triple effects where the three systems jointly interact with each other (Figure 1). Altogether 6 triple KNIs and 22 dual KNIs of FWE-Nexus effects have been specified.

As depicted in Figure 2 the multidisciplinary FWE systems are described following the associated demand and supply activities and then interrelated via the expected nexus-effects. The endorsed KNIs followed these effects and quantify the resulting impact associated with them. The total city energy demand is being specified by sector of consumptions with specific focus on energy needed for food and water provision, like energy for urban farming in agricultural sector, energy for food industry and energy for freight transport (including food and water), energy for cooking, etc (Hainoun and Loibl, 2021). The same applies for water being needed for irrigation, catering and beverage, household cooking, etc. The approach accounts only for the energy and water related to services and commodities provided within the city boundary. Energy and water embodied within the import food products are not considered. However, with focus on the different food supply routes (national, international) estimation are given for the transport distances to estimate the energy of food transport.

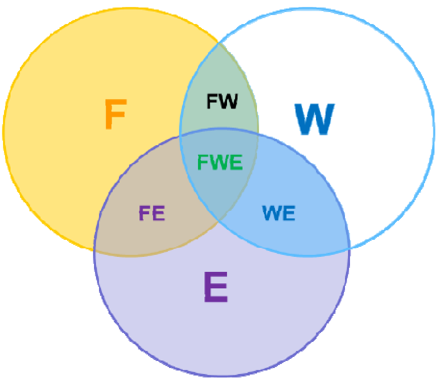

Figure 1: intersection of FWE systems and resulting KNIs

The established KNIs-concept is being integrated within the newly developed SUNEX-modelling framework focussing of formulating long-term future FWE-development scenarios (Hainoun and Loibl, 2021), (Doernberg et al, 2019). The scenario results are monitored and evaluated to specify the strength of coupling effects (nexus-grade) using the introduced KNIs.

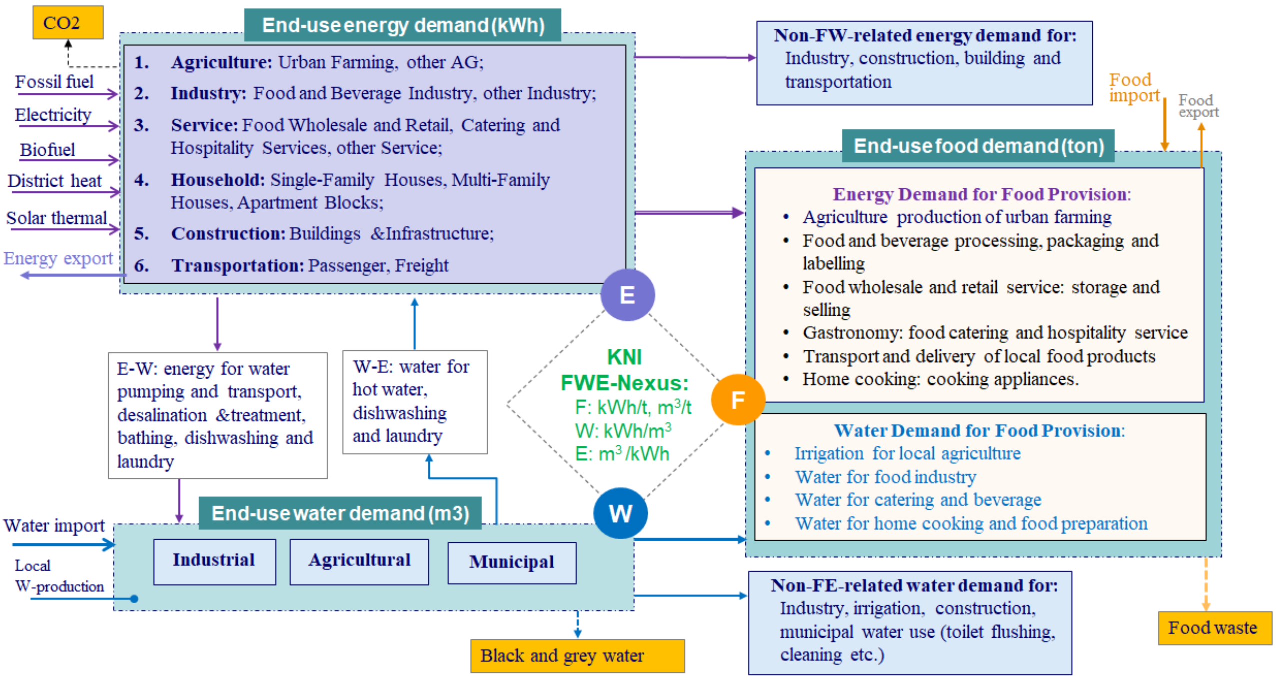

Figure 2: SUNEX-concept of the key nexus indicators (KNIs) to assess urban FEW-nexus.

3 APPLICATION

Tracing the main intersections along the FWE-supply chains 22 dual KNIs and 6 triple KNIs have been identified. Table 1 presents exemplary a selection among the identified KNIs. Permutation effects can play a roly if they are referring to different effects, like energy for water pumping and water for energy production (power plan cooling).

Considering the intersection of FWE-systems, the food perspectiveprovides the most interesting full FWE-Nexus-effects -along the food supply chains-, i.e. effects where the three systems are jointly interacting. These effects refer to the energy and water intensity in terms of energy and water amounts needed to generate one-unit of food. The resulting set of tripple KNIs are then associated to:

- Agricultural production of urban farming,
- Food and beverage processing,
- Packaging and labelling industry,
- Food wholesale and retail service (storage and selling)
- Household cooking and food provision in gastronomy (food catering and hospitality service within the service sector).

Besides, the mentioned steps along the food supply chain are associated with energy demand for food transportation (a dual KNI effect of energy for food).

With the set relation about the intensities -E(kWh)/F(ton), W(m3)/F(ton)- any future change in the amount or structure of food demand affects both energy and water demand via the specified KNIs that correlate with the existing nexus-effects. For example, the shift of demand per capita from meet to vegetable will reduce the energy and water demand due to the lower intensity of vegetable provision. From a holistic system perspective, this leads to reducing the CO2 emission per unit of food. However, within the city boundary, any increase of local production would increase the local energy and water demand (and land-use) which might feature a new challenge for the city given its limited energy, water and resources. The answer for the city-decision making is to choose the optimal balance between food import and local production considering the prevailing limits and constraints of the considered city. With focus on future city vision this challenge is exaggerating in relation with the set cities' goals in the EU to become carbon neutral latest by 2050.

Accordingly, the FWE Nexus-approach provides an interesting basis for a multisectoral decision making for a sustainable FWE strategy in respect to the city's long-term development goals (Ludlow et al, 2019).

	Affected Systems	Activity	Reference unit	Key Indicator
	FWE	Cooking (in household and HH): (all cooking appliances)	Per dwelling	E and W per F (kWh/t, m^3/t)
	FWE	Dishwashing (HH)	Per dwelling	E and W per F (kWh/t, m^3/t)
	FWE	Gastronomy (Ser): food catering and hospitality service	Per ton of food or related (GDP-VA)	E and W per F (kWh/t, m^3/t)
	FWE	Food and beverage processing, packaging and labelling	Per ton of food or related (GDP-VA)	E and W per F (kWh/t, m^3/t)
	FWE	Agricultural production of urban farming	Per ton of food or related (GDP-VA)	E and W per F (kWh/t, m^3/t)
	FWE	Food waste treatment	Per ton of food	E and W per F (kWh/t, m3/t)
	EF	Transport and delivery of local food products	Per ton or (GDP-VA)	E per F (kWh/t) or (kWh/$)
	EF	Refrigeration (in household)	Per dwelling	E per F (kWh/t)
	EW	Hot water (in household): (for bathing and showering)	Per capita	E per W (m3/kWh)
	EW	Laundry (in household)	Per dwelling	E per W (m3/kWh)
	EW	Irrigation: urban farming, private garden, public parks	Per m^2 of irrigated area	E and W per m^2 (kWh/m^2) (m3/ m^2)

Table 1: selection of main KNIs specified along the urban FWE-supply chain (FEW: intersection of Food-water-energy systems; EF intersection of Food and energy systems, EW: intersection of energy and water systems)

4 CONCLUSION

The introduced KNIs to monitor and evaluate the FWE-Nexus prove to be a valuable approach in supporting the development of sustainable urban FWE-strategies. The KNIs-concept has been realised within the integrated SUNEX-Modelling frame being under development. It has been successfully applied to cover the urban food supply chain covering (within the city boundary) form the agricultural production of urban farming up to the food provision in the household or gastronomy. Currently the concept is being applied to track and monitor the results of long-term sustainable FWE strategy for the cities of Vienna, Berlin, Bristol and Doha.

5 ACKNOWLEDGEMENT

This work has been carried out as part of the ongoing Project SUNEX running within the SUGI on FEW-Nexus of JPI-Urban Europe and the Belmont Forum (project number 730254). The authors would like to thank the Austrian Research Promotion Agency (FFG) for funding the Austrian Team (FFG- 867102).

1 ABSTRACT

country's spatial legacy. This planned segregation system left many South African cities with a spatial legacy that cannot support the ever-rising urban population, particularly the black African population that is ever migrating from rural to urban areas. The elements of concern include informal settlements, undesirable spatial configuration, single land use development, improper transportation and different forms of infrastructure. This paper aims to assess the level of spatial transformation across the city of Johannesburg. The paper adopts a case study research design and applies a mixed methods approach. Data was collected through interviews, a literature review on the spatial planning policies, and direct observations of the city's infrastructure. When the country gained its democracy in the year 1994, many policies and legislative frameworks were introduced, all of them having one primary objective: to transform South Africa spatially, mainly the cities. Since then, several policies and legislative frameworks have been implemented with the same vision of transforming the spatial configuration of the urban areas in the country. However, the spatial issues have remained the same for many if not all South African cities. Spaces in these cities remain divided along racial lines. The results revealed an improvement in the level of transformation across the municipality and an improvement in the policies and practice of spatial transformation. Developmental projects such as transit-oriented development have led to income elasticities for properties along the corridors of freedom. Overall, the paper recommends collaborative planning as a tool for assessing the performance of spatial transformation.

Keywords: Sustainable frameworks, collaborative planning, transit-oriented development, spatial transformation, Johannesburg

2 INTRODUCTION

The draconian planning system of the apartheid regime in South Africa played a huge role in shaping the country's spatial legacy. This planned segregation system left many South African cities with a spatial legacy that cannot support the ever-rising urban population, particularly the black African population that is ever migrating from rural to urban areas. Since the country gained its democracy in 1994, the government made it its mandate to introduce policies and legislative framework to address the challenges that were as a result of the apartheid system of spatial planning. All if not most of these policies and legislative frameworks had one primary objective which was to transform South Africa spatially, mainly the cities. Since then, many policies and legislative frameworks keep on being implemented, with the same vision as the ones before them, to transform the configuration of the country's urban areas spatially (South African City Network, 2016). However, the spatial issues have remained the same for many if not all South African cities. Spaces in these cities remain divided along racial lines (Ndhlovu, 2019).

With the noticeable undesired spatial legacy that the country inherited, spatial transformation is seen as the way forward to address socio-economic inequalities, racially divided spaces and transformation of the cities to provide equal opportunities and sustainable means of living for all citizens (Meerow & Miller, 2019). As Nkoane (2019) stated, South Africa needs spatial transformation not only to address the configuration of the urban areas, but also 'to embrace new spatial practices in respect of sustainability, liveability, resilience and facilitating technological innovation and economic structural change'. South Africa is noted as the most unequal society in the world; thus it is not surprising that South African spaces of cities reflect high inequality (Schensul & Heller, 2010). Johannesburg not being an exception adopted the spatial transformation approach to address the challenges such as inequality, injustices, and the social alienation that the city faces (Noyoo, 2019). Even with the implementation of many various policies, legislatives frameworks and projects across the city, the spatial configuration of the city is still highly fragmented. The efforts by the city mostly do not cater for the urban poor and as a result, the majority of the poor households continue to live in peripheral, poorly located areas with insufficient access to opportunities (Kruger, 2014). There is widespread poverty, criminality and a growing inequality which are the result of high unemployment rates that are unacceptably high; on the other side, the city's infrastructure is inadequate and not coping due to high migration. These aspects only highlight the reality which is that the city is not functioning properly spatially. This paper aims at assessing the level of spatial transformation across the city of Johannesburg with a focus on spatial planning policies, legislative framework and the practice of spatial transformation.

3 CONCEPTUAL FRAMEWORK

Transformation can be seen as 'a spatially defined, socially embedded process; with an interrelated series of materially driven practices, whereby the form, substance and overall dimensions of urban space are purposefully changed to reflect the principles of a more equitable social order' (Williams, 2000: 169). Williams (2000) continued to describe transformation as a 'programmatic, plan oriented, project directed effort to change the unequal access to and occupation/ownership of socio-politically differentiated space in South Africa. It is a multi-dimensional open-ended, fluid process of change, organically linked to the past, present and future' (Williams, 2000: 169).

It is increasingly acknowledged that 'spatial transformation' is required to address the injustices of the past. However, it is a concept with rather abstract and fluid meanings. The term has been used to refer to 'major urban change or restructuring', with very loose application in public policy, academic research and popular writing (Turok, 2014: 74). Spatial transformation is sometimes used interchangeably with the concept of urban restructuring, which can also refer to actions that reform while retaining the underlying power structures in order to minimise disruption and turmoil instead of pursuing fundamental change (Oranje, 2014).

Over the past two years, the understanding of the government's role in shaping and transforming cities and towns in South Africa has changed. The transformation of space is fundamentally linked to other key structural transformations: of institutions, capacity building, and the reconfiguration of power and influence (Williams, 2000). Fundamentally, the transformation of space can be equated to the living experience of urban dwellers. An inclusive, productive, sustainable and well-governed city is one in which residents experience a high quality of life, and both benefit from what the city offers and contributes towards making and shaping the city. It is important to understand that certain pathologies manifest in the urban environment when people are not able to determine, influence and ultimately access opportunities (Max-Neef, 1992).

4 STUDY AREA

Spatial transformation is critical for the growth of cities in South Africa as it addresses the challenges such as injustice and undesirable spatial configuration of the cities, making it an indispensable factor for the development in the cities. However, the current policies and legislative framework seem to be missing certain aspects to make the implementation of spatial transformation successful. Thus, there needs to be continuous improvements in strategies, procedures and elements that inform spatial transformation of the country. The Gauteng province is also affected by this challenge, and this being the economic hub of the country, it affects the development prospects of the ountry as a whole, both economically and socially.

The City of Johannesburg is faced with a mounting pressure of growing demand of infrastructure and services delivery.This is clearly visible from the protests that happen almost every year. The increase in population of the city and the demand for services and infrastructure is not being met by the investment in infrastructure and this is partially as a result of the current spatial planning policies and practices in the city. This has resulted in increased inequality, unaligned and uncoordinated development, continued inefficient spatial development, decaying urban infrastructure, locational disadvantage in projects aimed at assisting the urban poor, built environment investment not resulting in inclusive economic development and spatial fragmentation (SACN, 2016: 50-58). The scope of this study focuses on the city of Johannesburg, which is in Gauteng Province of South Africa as shown on the figure below (figure 1).

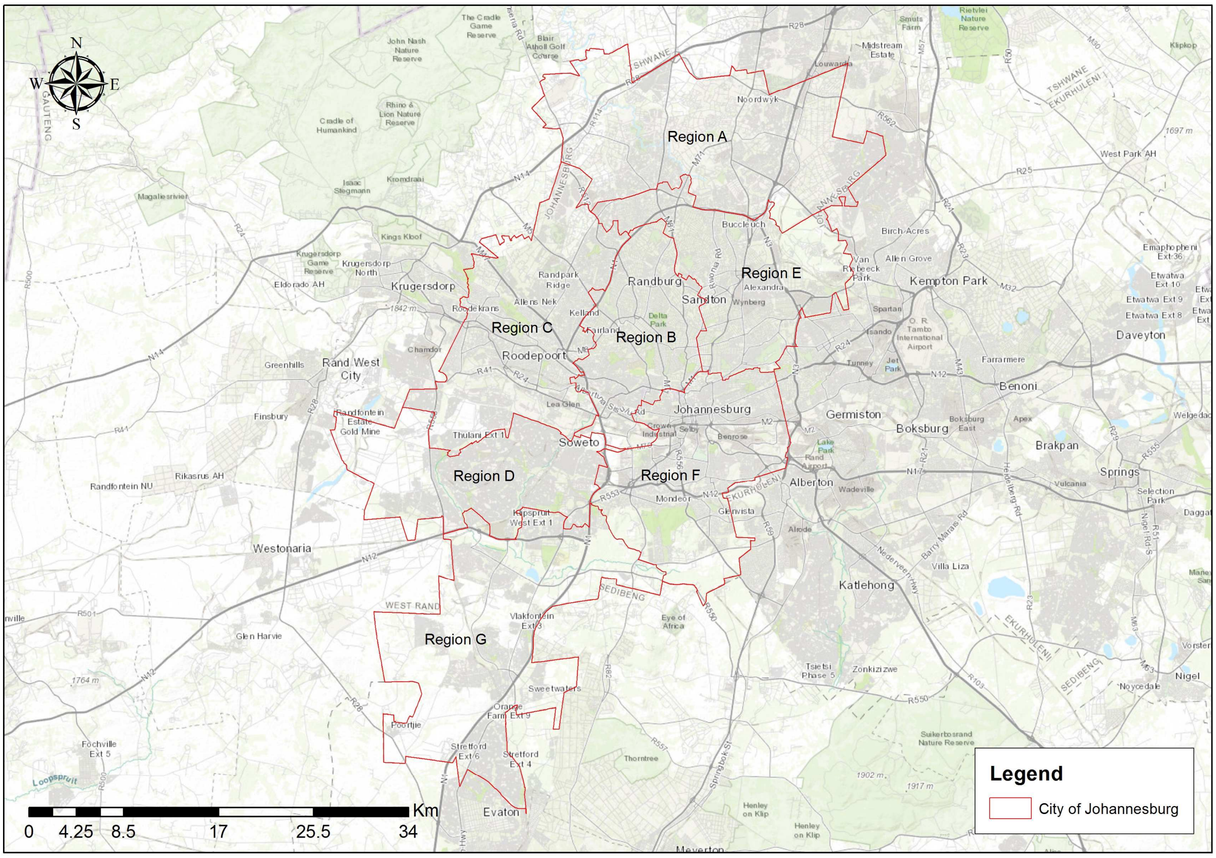

Figure 1: City of Johannesburg

5 METHODOLOGY

This study adopted the mixed method approach to fully explore the research question: 'What is the current state of policy and practice of spatial transformation in the City of Johannesburg?'. A case study design was chosen to extract meaning from the experiences of residents living in the city of Johannesburg Metropolitan Municipality. Located in the Gauteng Province of South Africa, the City of Johannesburg is one of the three metropolitan municipalities in this province. It shares the borders with the MetropolitanCity of Tshwane to the North, the Metropolitan City of Ekurhuleni to the East, Sedibeng District to the South and West Rand District to the West.

This study relied heavily on interviews and observations of the situation in the city of Johannesburg. Interviews were conducted with 30 respondents, in which 7 of them were from the city's planning department, 7 were private developers within the city's jurisdiction and 16 were people who reside in the city. Interviews with the municipal officials were unstructured and the ones conducted with residents were structured. Due to Covid-19 lockdowns in South Africa, the interviews were conducted via Zoom and Microsoft Teams. Observations and literature were also used to support the information gathered using interviews. For the literature review on spatial planning policies, a desktop study was used as the primary means of obtaining data. Text analysis was applied to qualitative data from interviews. Town planning professionals, private developers and community residents all provide their unique experience which were all used as the basis of analysing the current state of spatial transformation and spatial planning within Johannesburg.

6 FINDINGS

6.1 Policy and Legislative framework for spatial planning and transformation

The section of the interviews focused on the policy and legislative framework of the city. Only policies and legislative frameworks that relate to spatial planning and spatial transformation were reviewed and assessed in order to determine how they help in enforcing spatial transformation in the city of Johannesburg. The

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

policies and legislations that were reviewed included SPLUMA, GDS, IDP, SDF and Corridors of Freedom Initiatives.

The Spatial Planning and Land Use Management Act (SPLUMA) is South Africa's national legislation governing all spatial planning. It was enacted in 2013 and came into effect in July 2015. "In its mandate to spatially transform the country, SPLUMA introduces a new spatial planning system which now places the local municipality at the centre of spatial planning and decision making related to land use management. SPLUMA basically reinforces the vision set out by the NDP (National Development Plan) to deal with the serious socio-economic issues crippling South Africa through spatial transformation" (Spatial Transformation Conference Report, 2014). SPLUMA aims at closing the gap on the racial divide spatially and the transformation of the country's settlement patterns. It also seeks to address the legacy of inefficient, discriminatory, and costly special patterns that are a burden on the country's public resources (Spatial Transformation Conference Report, 2014). The act also plays an important role in the restructuring of South African cities (SPLUMA, 2013). SPLUMA principles are content focused which translates into the spatial transformation issues that the country is seeking to address through spatial planning. In Johannesburg, SPLUMA was found to be contributing greatly to the spatial transformation of the city. This was possible because it enforces intergovernmental cooperation. The cooperation of the three spheres of government contributed to the strategic spatial planning of the city which then translated to spatial transformation of Johannesburg. The proper implementation of SPLUMA is noted to be benefiting in terms of transforming space within Johannesburg, however, there are challenges with regards to the implementation of this legislation within Johannesburg. The key challenges are as follows: (1) Some principles are not clearly explained (vagueness); (2) there is no target specification, the legislation does not show which principle should be prioritised; (3) Co-ordination is complex in the sense that there is an "absence of a hierarchical relationship between the spheres of government" (Spatial Transformation Conference Report, 2014).

The SDFs)Spatial Development Frameworks) are also noted as important for spatial change or transformation of the city, mainly because the SDFs indicate the spatial vision for the city and the means of implementation (CoJ SDF, 2016). The breaking down of the SDF into eight Regional Spatial Development Frameworks meant that the city could give more detail into the plans and the implementation for each of the city's region. The SDF has been successful to some extent in dealing with some of the major issues in Johannesburg's spatial and social landscape which are increasing pressure on the natural environment; spatial inequalities and the job-housing mismatch; exclusion and disconnection; and inefficient residential densities and land use diversity.

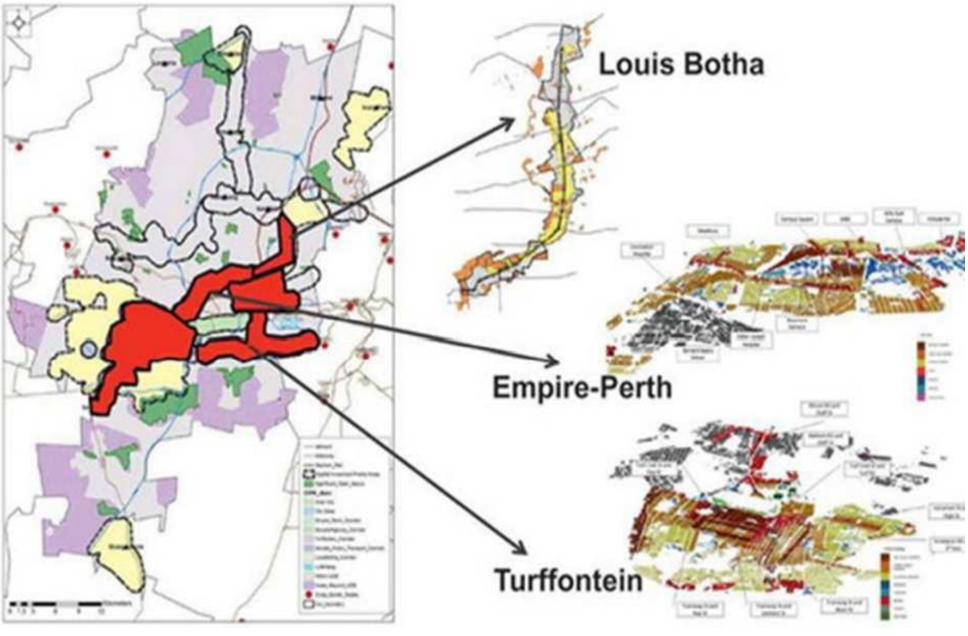

Figure 2: Corridors of Freedom in Johannesburg (City of Johannesburg, 2013).

The City of Johannesburg aimed at achieving "well-planned transport arteries linked to interchanges where the focus will be on mixed-use development of high-density accommodation, supported by office buildings, retail development and opportunities for leisure and recreation" (COJ, 2013, pp. 2, 4). The city had planned to use the Corridors of Freedom to achieve this. The Corridors of Freedom transformed the entrenched settlement patterns by bringing access to economic opportunities and access to jobs and growth. Through the Corridors of Freedom Johannesburg was able to make a decisive turn towards a low-carbon future with an eco-efficient infrastructure that underpins a sustainable environment. Overall, the Corridors of freedom played a significant role in the urban and spatial planning of Johannesburg; however, the initiative does not have far reaching impacts across the city. Only a few areas in the city benefit from these types of development. The City of Johannesburg has already implemented three of these Corridors of Freedom, making it ahead of its counterpart municipalities in the pursuit of achieving spatial transformation the three areas: Louis Botha, Empire-Perth and Turffontein as shown on the figure below (figure 2).

6.2 Strategies, procedures and elements that necessitated and informed spatial planning and transformation

When the study was being carried out it was noted that for sa patial transformation vision to be achieved, there needed to be a transformation of institutions and intergovernmental relations. Effective intergovernmental relations play an important part in the spatial transformation of a city. These intergovernmental relations assist in recognising the role played by the local government. “The scope and pace of change in South Africa are also influenced/determined by the extent to which public institutions adjust to and comply with the current directives of transformative planning” (Williams, 2000: 170).

As one of the municipal officials interviewed notes, “one of the challenges we face is that there is a lack of integration within the departments in the city, thus information doesn’t smoothly move across all 15 departments of the City of Johannesburg”. There clearly is a need for the municipal departments and the municipality as a whole to move from this traditional silo approach in which each department aims to use the resources to fulfil their mandate or their own targets. The local level is the best place to achieve spatial transformation, and this cannot be achieved through a ‘fragmented approach’; however it requires an ‘institutional arrangement’ that is able to respond to the coordination, integration and nuance that may be required. As the COGTA (2016) notes, there is a need for the intergovernmental and interdepartmental relations to be strengthened so as “to drive the agreed policy, fiscal and regulatory changes, and to steer the priorities of the urban agenda” (COGTA, 2016: 101).

There is a need to transform politics and power. Williams (2000) argued that the “radical change needed to disrupt the power imbalances that exist within South Africa’s urban spaces would not be an easy or smooth process”. Mainly because there are still numerous vested interests in keeping Johannesburg the way it is and not equalising the power relations amongst black and white communities. Amongst the community members interviewed for this study, most still feel that white people are the ones that drive development in the city, mainly because they have the means (capital) and because they pull the strings of municipal officials behind the scene. Black communities feel that they are not being involved in the development processes as much as white people. They feel that they are excluded. According to Williams (2000), “People-driven development” helps in terms of the transformation of “social relations of power which give rise to the patterns of uneven development in South African society” (Williams, 2000: 172). To date, two decades later, the argument by Williams is still very valid. The City of Johannesburg is faced with political power-brokering, corruption, nepotism and inefficiency amongst some of the officials which all pose a great challenge to the city achieving its desired spatial transformation. The private sector and individuals (especially from the private sector) who power over decisions or even challenge decisions that are made which, in turn, slows down progress of spatial change as well as social integration. This is clearly visible in most suburbs for the middle income class and the high-income class. One classic example was when the Rosebank community objected to the construction of the BRT route through the area (RMD, 2011)/ However, the construction of this BRT was aimed at integration and sustainable transport to accommodate all social classes. This power display dynamics needs to be changed for spatial transformation to take place properly and with ease.

Transit Oriented Developments (TOD) refer to the “utilisation of an age-old phenomenon of urban development in terms of which more intensive non-residential and higher-density residential development concentrates at public transport (notably train and later on light-rail) stations” (Boarnet and Crane, 1997; Peters and Novy, 2012). In Johannesburg, these are done in a form of corridors of development. The City currently has three of those which are: (1) Louis Botha; (2) Empire-Perth; and (3) Turffontein. In Johannesburg’s perspective, these play an important role in the spatial transformation of the city because they are the ones that connect most townships to the central business district (CBD). They increase densities along the transport routes which are mostly low densities, and are “physically and tangibly restructuring the highly inefficient sprawled-out city” (Oranje, 1999). In the city, the Transit Oriented Development (TOD) in its purest form is still limited, although if these kinds of developments were increased, it would be a right direction towards achieving the desired spatial transformation.

State-led Urban Renewal Projects aim to upgrade neighbourhoods and suburbs that are in a state of distress or decay. These projects would address the decaying urban areas and tackle challenges, such as poor physical infrastructure, dull urban areas, poor community services and deteriorating inner city housing. Currently the Johannesburg urban renewal projects are undertaken by the private sector. One example of this is the Maboneng Precinct. The end results of these projects being run by the private sector is that the developments do not intend to cater for the urban poor. Once properties are re-developed, the rents become so high that most people cannot afford them anymore, forcing them to relocate to other parts of the city. Urban renewal projects in Johannesburg should be undertaken by the municipality. It should form part of its broader projects of expanding the economy of the city as well as housing projects. In that sense, the city can achieve spatial transformation at the address the spatial justice issue by ensuring access and inclusion to the previously disadvantaged communities. In Seoul the state-led urban renewal proved to be effective, “this new form of high-density housing proved to have provided a longer term, (more) lasting answer to addressing the needs of a growing economy and expanding middle class” (Kyung, 2011: 10). However, the external stakeholders do not believe that this can work on Johannesburg. They feel that if state-led urban renewal projects are implemented, they will not work. They base their claims on the fact that most state led developments are mostly not properly maintained and they run down easily, thus coming to a conclusion that the urban renewal projects should be left to the private sector or that there should be a public-private partnership to make housing affordable.

6.2.1 Transformation of management and capacity

Numerous changes have occurred over the past two decades across the built environment, requiring a fundamental shift in the skills and capacity needed to transform and deal with spatial transformation and spatial planning issues. For instance, the skills needed to deliver housing products in the human settlements sector are now different from the ones that are needed to carry out ‘sustainable human settlements’, thus these two require co-production and cross-sectoral cooperation. This also applies to the transport sector. Achieving better transport systems needs a better integration between the modes of transport in the city. All this can be achieved through building capacity and skills of officials with the involvement of the communities, “so that they have the knowledge and are empowered to influence and determine city form and function effectively” (Williams, 2000). The current skills set of many officials is ‘silo’, their skilla are related to a specific node. However, they need to be able to integrate different aspects of planning to achieve spatial transformation.

6.2.2 Intensified human settlements

Johannesburg, like most of South African cities, is characterised mainly by “low-density urban sprawl and higher densities on the outskirts of cities, not the inner cities” (SACN, 2016). This is mainly due to the apartheid planning that placed the majority black population on the outskirt of the city, and it is also as a result of the development of the low-cost housing on the outskirts of the city because land is cheaper. An example of this is the historical Sowetan Townships.

As shown in figure 4.8, Soweto is a low-density settlement in the outskirts of the Johannesburg CBD. According to the Census 2011, the population of Soweto is at 1,271,628 with a population density of 6,357.29 inhabitants per square kilometre (16,465.3/sq mi). “Better located and integrated development is critical to reducing urban sprawl and spatial economic transformation of cities” (Bertoldi, 2015). The land located in close proximity with the city is usually expensive, thus it becomes important to make the best use of this land. This land can be used for high rise buildings to accommodate greater population density, and this could contribute to ‘enhanced efficiency in the city space economy’ (Bertoldi, 2015). Currently, the government’s emphasis has shifted from delivering mass housing to delivering sustainable human settlements. Johannesburg in particular has acknowledged that there is a need for locating housing in ‘well-located urban neighbourhoods. However, “political and private developer vested interests have so far trumped concerns for better located, more compact and integrated housing alternatives”.

Figure 3: Soweto Township (Source: Mason, 2017)

6.2.3 Improved mobility and access to public transport

Johannesburg commuters face a daily challenge of security concerns, overcrowding, high cost of travel and long commuting times and this is most apparent in low-income groups who live in the outskirts of the city and work in the CBD. Thus, providing a public transport system that is affordable and reliable would definitely go a long way, and would help in reducing the traffic congestion that the city CBD encounters in the early morning hours and late afternoon when people come back from work. Reducing the cost of public transport and travel time enhances urban spatial connectivity and inclusiveness and enhances urban resilience. Consolidating city-level public transport presents the greatest opportunity to reshape the spatial patterns of Johannesburg.

6.3 Spatial Transformation Policy and Practice Outcome in Johannesburg

Since 1994, the spatial planning policy and practice have undergone some serious changes in Johannesburg and South Africa as whole. There have been some positive outcomes of the spatial planning policy and practice in transforming Johannesburg. However, the effectiveness of the spatial planning policy and practice on restructuring City of Johannesburg is being questioned as there is little evidence showing that this being achieved.

Dimension	Yes	No
Clear horizontal coordination with spatial plans of adjacent region	3	4
Clear horizontal coordination with spatial plans of adjacent municipalities	7	-
Explicit vertical alignment with provincial spatial plans and strategies	7	-
Clear consideration of national spatial development plans and perspective	6	1

Table 1: Institutional coordination and alignment of Regions in City of Johannesburg (Source, Author, 2020).

6.3.1 Improved Institutional Coordination and Alignment

There has been improved management of urban growth and improved governance. There has been quite a noticeable alignment between various departments within the municipality. “Spatial plans with other sector planning activities within municipalities and with the planning of neighbouring municipalities are aligned” one of the officials said during the interview. The regional SDFs of various regions within the municipality have their plans aligned which improves institutional coordination, but this is not the case for all the regions. Some regions still need to improve their coordination and alignment. Through literature review of various SDFs, the author came up with the following table that shows the level of alignment of the Regional SDFs with the other SDFs that are applicable to the city. The table below shows the alignment of the Johannesburg Regions SDFs with the Overall City’s SDF, Provincial SDF and the National SDF.

6.3.2 Increased Physical and Socio-economic Integration

"It has been argued that spatial governance in places characterised by existing levels of social inequality and racial polarisation will continue to be ineffective" (Robins, 2002). Johannesburg has shown much effort in combating the social inequalities. There are projects that are aimed at unification of the urban fabric and densification of human settlements, but the city is still facing problems in combating challenges of physical and socio-economic integration. There are projects within the city that are aiming at the 'integration of the various aspects of land development' (social, economic, institutional and physical), the integration of land development in rural and urban areas in mutual support and the integration of residential and employment opportunities in close proximity to each other. This is important because integration is an integral part of spatial planning policies, right from the local plans all the way to the National Development Plan 2030, which "contains as many as individual references to the concept of integration" (National Planning Commission, 2012). As contained in the NDP, each municipality is meant to have "explicit spatial restructuring strategy including identified priority precincts for spatial restructuring" and "critical interventions to redress past social segregation" (National Planning Commission 2012, p. 286). As much as this is noted as an important aspect by the municipality, they still have a long way to achieve a socio-economic integration.

6.3.3 The city's Space Economy

"One of the key tension points in spatial planning in South Africa is the interplay and associated trade-offs between the need for economic growth and competitiveness on the one hand, and for socio-economic redress on the other" (Jenkins and Wilkinson, 2002). In this sense, cities have to compete globally with other cities in order to improve their financial position as well as developing the local skill set. Johannesburg competes with the world, and is currently ranked as the economic hub of South Africa. As such it contributes 17% of the total output of the South Africa and enabled the spatial planning policies and practices within the city. Johannesburg does not only hail as the financial capital of South Africa, but it is also ranked the first of the richest cities in the African continent.

6.3.4 Infrastructure Development and Capital Investment

"Infrastructure provision is one of the most powerful forces shaping urban areas" (Doxiadis, 1970). It cannot be denied that the infrastructure in Johannesburg is amongst the most advanced in the country and in Africa. The critical role of infrastructure and investment in achieving spatial planning objectives was confirmed by Healey (2004, p.46) by describing spatial planning as "self-conscious collective efforts to reimagine a city, urban region or wider territory and translate the results into priorities for area investment, conservation measures, strategic investment in infrastructure, and land use principles". Todes (2008, p. 11) further emphasises this view, stating that "infrastructure planning with its own spatial logic was more effective than spatial planning in shaping the spatial structure of cities." The NUDF also identified improved urban infrastructure and service delivery systems as one of the strategic outcomes for urban areas in South Africa (Republic of South Africa, 2009). There are specific issues in Johannesburg that adversely affect the integration of infrastructure development and capital investment. The problem involves the fact that spatial planning is the only dominant influence of low-income public sector-driven housing projects funded by the Department of Human Settlements, the shaping of cities through commercial and residential development in the private market sector, and the emphasis on 'mega-projects' disjointed from spatial planning. As one of the municipal officials notes, there is a need for planners to "call for the replacement of the traditional piecemeal pursuit of capital projects with a more coherent long-term view focused on selected areas and policy themes".

Informal economy in the urban environment can stretch to different dimensions, like the development of infrastructure, land and housing, and processes of decision-making (Roy, 2005). Within Johannesburg's context, the notion of urban informality is linked to the activities of the informal economic sector and to informal housing and services, both of which often involve some measure of illegality. Johannesburg has an informal economy that is vibrant and growing. The analysis of the Johannesburg SDFs clearly demonstrates that in spatial planning, informality remains largely unrecognised. Only two of the plans reviewed contained explicit strategies relating to the informal sector, with an additional six reflecting certain strategies that at least imply consideration of certain aspects of the informal sector. Those plans, which included informal sector strategies, were almost exclusively concerned with upgrading informal housing settlements and with broad strategies for managing and controlling informal trading areas.

6.4 The proposed strategies for improving the state of spatial transformation

The city should use economic bridging plans. Spatial strategies should be highlighted by the nodes and corridors system of local economic development which is an economic bridging plan. Nodes of economic activity should be developed in central parts of townships and linked to other parts of the city using corridors based on existing transportation networks. The underlying concept of the nodes and corridors strategy should be that while people continued to live apart, economic activity could be spurred that bridged racial residential lines.

There should be an increase in economic density. To support its economic transformation and move up the industrial value chains, Johannesburg needs to significantly increase its economic density to reap productivity gains derived from agglomeration. A project which has good potential as an example is the Corridors of freedom developments across the city, if planned well, it could accommodate a significant amount of the region's projected growth and potentially become a new engine of growth for the city.

7 CONCLUSION

The paper sought to assess the level of spatial transformation across the city of Johannesburg. The paper went on to assess policies and legislative framework on the city's spatial transformation; the strategies that the city uses to promote and enable transformation and inclusivity within the city; and lastly focused on the current outcomes of spatial planning policies and practice within the city. The results revealed an improvement in the level of transformation across the municipality and an improvement in the policies and practice of spatial transformation. Developmental projects such as transit-oriented development have led to income elasticities for properties along the corridors of freedom. Overall, the paper recommends collaborative planning as a tool for assessing the performance of spatial transformation.

Ist der Onlinehandel Wettbewerbstreiber oder gar "Rettungsanker" für unsere Städte? Eine modellgestützte Analyse der Determinanten des Einkaufsverhaltens im Multi- und Cross-Channel-Kontext

Thomas Wieland

(Dr. Thomas Wieland, Karlsruher Institut für Technologie, Institut für Geographie und Geoökologie, Abt. Humangeographie, Kaiserstraße 12, 76131 Karlsruhe, thomas.wieland@kit.edu)

1 ABSTRACT

Multi- und Cross-Channel-Retailing gewinnen stetig an Bedeutung, weshalb ein gesteigertes Interesse an der Erklärung des (räumlichen) Einkaufsverhaltens im Multi-Channel-Kontext besteht. Die Standorttheorie des Einzelhandels liefert hier, ebenso wie bisherige Modelle der Einkaufsstättenwahl, keine Antworten, da in beiden Fällen "nur" der stationäre Einzelhandel berücksichtigt wird. Die Forschung zum Multi-Channel-Einkaufsverhalten beschäftigt sich zwar mit den Einflussgrößen der Kanalwahl, berücksichtigt aber weder die vorhandene räumliche Angebotsstruktur des stationären Handels noch die Möglichkeit von Cross-Channel-Einkäufen. Weitere Forschungslücken liegen in der seltenen Verbindung der Erklärungsansätze des Einkaufsverhaltens sowie in methodischen Problemen (z.B. hinsichtlich Repräsentativität von Befragungen). Der vorliegende Beitrag beschreibt die wichtigsten Eckpunkte eines laufenden Forschungsprojektes, in dem die genannten Aspekte aufgegriffen werden. Anhand mehrerer Einzelhandelsbranchen werden die Determinanten der Einkaufsstättenwahl im Multi-Channel-Kontext untersucht, d.h. unter den Bedingungen, dass sowohl stationäre als auch Online-Anbieter zur Verfügung stehen und außerdem viele Anbieter Cross-Channel-Shopping ermöglichen. Die empirische Grundlage der Untersuchung ist eine schriftlich-postalische Befragung zum Einkaufsverhalten in zwei deutschen Untersuchungsgebieten. Die Analyse individueller Einkaufsentscheidungen und -ausgaben erfolgt mit Hilfe eines mikroökonometrischen Modells zur Einkaufsstättenwahl, das eine deutliche Erweiterung bestehender Modellansätze darstellt. Im Ergebnis zeigt sich u.a., dass die Kanalpräferenz (stationär oder online) weniger von demographischen Faktoren abhängt, sondern von individuellen Einstellungen und dem Wohnort. Die Einkaufsstättenwahl wird vorrangig durch anbieterabhängige Transaktionskosten (z.B. Fahrtzeit, Liefergebühren) und deren Charakteristika erklärt. Es zeigt sich z.B. die Relevanz der Cross-Channel-Integration von Handelsbetrieben, wenngleich der „click and collect"-Service tendenziell überschätzt wird. Der Modellansatz und die Ergebnisse des Projektes haben praktische Relevanz, u.a. für die Raumordnung, betriebliche Standortplanung sowie das Citymarketing.

Keywords: Cross-channel retailing, Modell der Einkaufsstättenwahl, Einkaufsverhalten, Onlinehandel, Ökonometrie

2 HINTERGRUND DES PROJEKTES

Die Relevanz des Onlinehandels steigt stetig, was die Standorte des stationären Einzelhandels (Innenstädte, Stadtteilzentren) einem erheblichen Wettbewerbsdruck aussetzt (BBSR, 2017; Stepper, 2016). Gleichzeitig werden Multi- und Cross-Channel-retailing – zumindest für vertikal integrierte Handelsunternehmen – immer selbstverständlicher; die Digitalisierung des Einzelhandels kann demnach auch förderliche Effekte für bestehende Handelsstandorte haben (Battermann/Neiberger, 2018; Heinemann, 2015; Rumscheidt, 2016; Wieland et al., 2020). Von großem Interesse ist daher das Konsumentenverhalten im Multi-Channel-Kontext, das bisher – grob zusammengefasst – anhand folgender Forschungsstränge untersucht wurde:

- Transaktionskosten des Einkaufs, z.B. Erreichbarkeit (des stationären Handels), Lieferkosten und
- -zeit (im Onlinehandel) (z.B. Chintagunta et al., 2012; Hsiao, 2009; Schmid/Axhausen, 2019)
- Räumliche und andere situative Erklärungsgrößen, z.B. Verfügbarkeit von stationärem Handel, Wohnort der Konsumenten (Innovations-Diffusions-Hypothese vs. Effizienz-Hypothese), sozio-demographische Faktoren der Konsumenten wie Alter, Geschlecht etc. (z.B. Beckers et al., 2018; Cao et al., 2013; Clarke et al., 2015; Zhen et al., 2018; Wiegandt et al., 2018)
- Einstellungen zum Onlinehandel im Sinne einer „Online-Affinität" bzw. Abneigung dem Onlinehandel gegenüber (z.B. Bezes, 2016; Schmid/Axhausen, 2019; Zaharia/Hackstetter, 2017)
- Der bisherige Forschungsstand weist v.a. drei erhebliche Defizite auf:

- Die Studien beziehen sich meist nur auf einen der genannten Aspekte (Ausnahmen z.B. Schmid/Axhausen, 2019; Wiegandt et al., 2018); eine gleichgewichtige Berücksichtigung aller genannten Aspekte wurde bisher nicht erreicht.
- Es zeigen sich Defizite hinsichtlich der Repräsentativität bzw. Verallgemeinerbarkeit der Ergebnisse: Bisherige Arbeiten stützen sich häufig auf Online-Befragungen und/oder schließen bewusst nur Multi-Channel-Kunden ein (z.B. Beckers et al., 2018; Cao et al., 2013; Zaharia/Hackstetter, 2017). Dies schließt Kunden aus, die über keinen Internetanschluss verfügen oder sich dem Onlinehandel verweigern. Zudem sind i.d.R. Minderjährige, die noch keinen eigenen Haushalt führen, von den Befragungen ausgeschlossen. Einige Studien beziehen sich nur auf Kunden einzelner Unternehmen (z.B. Bezes, 2016; Chintagunta et al., 2012). Studien mit Repräsentativitätsanspruch bezüglich der Gesamtbevölkerung sind selten (z.B. Schmid/Axhausen, 2019; Wiegandt, et al. 2018; zur Repräsentativität bei Befragungen in der Geographischen Handelsforschung siehe Rauh/Hoffmann, 2020). Wesentliche Ergebnisse basieren zudem auf Befragungsexperimenten (z.B. Hsiao, 2009; Schmid/Axhausen, 2019) und wurden bisher nicht anhand von realem Einkaufsverhalten überprüft.
- Die Analyse/Modellierung erfolgt in fast allen bisherigen Arbeiten mit Kanalwahlmodellen, wobei entweder die Wahrscheinlichkeit oder die Häufigkeit von Onlinekäufen untersucht wird (z.B. Beckers et al., 2018; Cao et al., 2013; Clarke et al., 2015; Hsiao, 2009; Schmid/Axhausen, 2019). In einigen Fällen erfolgt die Auswertung auch bivariat (z.B. Wiegandt et al., 2018). Bis auf wenige Spezialfälle fehlt die Integration des Onlinehandels in ein Modell der Einkaufsstättenwahl, wie es in der (geographischen) Handelsforschung seit Jahrzehnten eingesetzt wird (Suel/Polak, 2018; Überblick zu Modellen der Einkaufsstättenwahl z.B. Wieland, 2015). Die geographische Handelsforschung beschäftigt sich maßgeblich mit der Einkaufsstättenwahl, der theoretischen Erklärung ihrer Determinanten und ihrer Modellierung; räumliches Einkaufsverhalten ist ein zentraler Gegenstand der Standorttheorie des Einzelhandels, bezieht sich jedoch ausschließlich auf stationäre Handelsbetriebe bzw. Angebotsstandorte (z.B. Huff, 1962; Überblick z.B. Brown, 1993).

3 UNTERSUCHUNGSKONZEPT UND METHODIK

3.1 Ziele und Fragestellungen, Forschungsansatz

Ausgehend von den o.g. Forschungslücken verfolgt das Projekt u.a. folgende Ziele:

- Integration der o.g. Ansätze zur Erklärung des Einkaufsverhaltens in eine Untersuchung
- Empirische Erfassung von realem Einkaufsverhalten unter der Bedingung von Repräsentativität im Hinblick auf alle Konsumententypen (inkl. Nicht-Onlinekäufer)
- Annähernde Abbildung der räumlichen Heterogenität des Untersuchungslandes (Deutschland)
- Integration des Onlinehandels bzw. genauer: des Multi-Channel-Shoppings sowie der Option des Cross-Channel-Shoppings in ein Modell der Einkaufsstättenwahl

Das Projekt geht u.a. den folgenden Forschungsfragen nach:

- Wie wirken sich die Transaktionskosten auf die Einkaufsstättenwahl zwischen den zur Verfügung stehenden (Online-/Offline-)Einkaufsalternativen aus?
- Wie wirkt sich das stationäre Handelsangebot vor Ort auf die Einkaufsstättenwahl aus?
- Wie wirken sich die „Online-Affinität“ der Konsumenten sowie deren sozio-demographische Eigenschaften auf die Kanal-/Einkaufsstättenwahl aus?
- Wie wirkt sich die Cross-Channel-Integration von Anbietern auf die Einkaufsstättenwahl aus?

Um die obengenannten Fragen zu beantworten, wird das Konsumentenverhalten im Multi-Channel-Kontext mit einem Revealed-Preference-Approach untersucht, d.h. dass auf die Präferenzen der Konsumenten auf der Grundlage realer (Einkaufs-)Entscheidungen der Vergangenheit geschlossen wird (Train, 2009). Die Analyse erfolgt mit einem quantitativen Modell der Einkaufsstättenwahl; diese Modellfamilie erklärt räumliches Einkaufsverhalten auf der Basis von Nutzenfunktionen, die sich aus angebotsseitigen (d.h. Eigenschaften der Einkaufsalternativen) und nachfrageseitigen Attributen (d.h. Konsumenteneigenschaften) zusammensetzen. Ökonometrische Einkaufsstättenwahlmodelle gehen dabei von Nutzenmaximierung der Konsumenten aus, wobei stets nur ein Teil dieses Nutzens durch das Modell erklärt werden kann. Das Wahlverhalten wird als probabilistisch angenommen, d.h. in Form von Auswahlwahrscheinlichkeiten, wobei die Alternative mit dem größten Nutzen die höchste Wahrscheinlichkeit hat (Wieland, 2015). Da im vorliegenden Fall individuelle Eigenschaften der Konsumenten berücksichtigt werden, ist ein mikroökonometrisches Modell erforderlich.

Berücksichtigt werden vier Einzelhandelsbranchen aller drei Zentralitätsstufen mit unterschiedlichen Online-Marktanteilen (HDE, 2019), nämlich Lebensmittel, Bekleidung, Elektronikartikel und Möbel. Für die Analyse ist sowohl die Erfassung der Angebotssituation (d.h. der Einkaufsalternativen des stationären und Onlinehandels) als auch des Konsumentenverhaltens (d.h. getätigte Einkäufe) sowie weiterer Attribute der Konsumenten (u.a. Einstellung zum Onlinehandel) in Form einer Konsumentenbefragung notwendig.

3.2 Untersuchungsgebiete

Es wurden zwei siedlungsstrukturell unterschiedliche Verflechtungsräume, die in der Raumordnung als zusammengehörige Regionen definiert sind, als Untersuchungsgebiete ausgewählt; ein Wahlkriterium war hierbei, dass die Untersuchungsgebiete alle Kreis- und Gemeindetypen des BBSR beinhalten, um Großstädte, deren suburbanes Umland, Kleinstädte sowie ländliche Gemeinden abzudecken. Ein weiterer Grund für die Auswahl waren pragmatische Erwägungen im Sinne von Arbeitseinsparungen durch bereits bestehende Vorarbeiten in diesen Gebieten. Ausgewählt wurden 1) der (ehemalige) Regionalverband Südniedersachsen und 2) der Regionalverband Mittlerer Oberrhein (Überblick siehe Tab. 1 und Abb. 1).

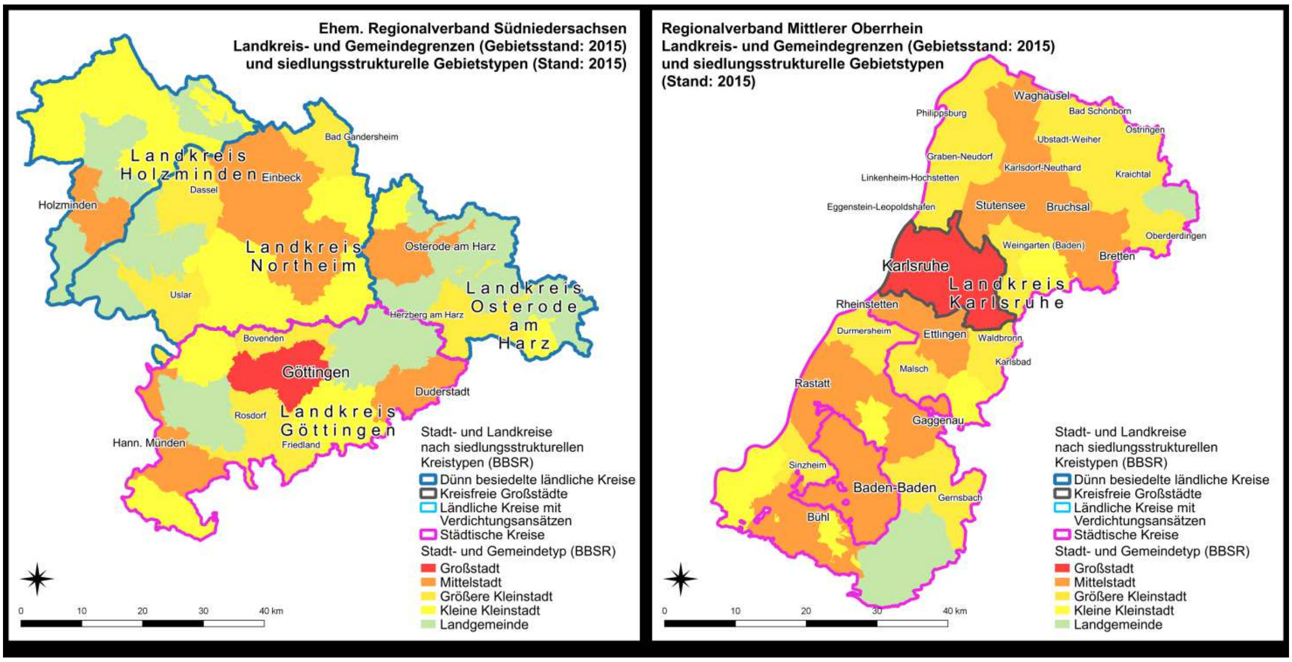

Abb. 1: Siedlungsstruktur der Untersuchungsgebiete.

	1 – (Ehem.) Regionalverband Südniedersachsen	2 – Regionalverband Mittlerer Oberrhein (= IHK-Bezirk Karlsruhe)
Bundesland	Niedersachsen	Baden-Württemberg
Einwohnerzahl 2018 [Anzahl]	531.814	1.043.465
Anteil Einwohner 65 u. älter 2018 [%; BRD: 21,5]	23,7	20,6
Bevölkerungsdichte 2018 [EW/km2]	143,22	488,20
Arbeitslosenquote 2018 [%; BRD: 5,2] *	5,7	3,2
Einzelhandelskaufkraft (MB Research) 2019/2020, [Index; BRD = 100] *	95,3	103,9
Raumstruktur (Kreis- und Gemeindetypen)	1 Großstadt + überw. dünn besiedelte ländliche Kreise mit Kleinstädten u. Landgemeinden	1 Großstadt + städtische Kreise mit überw. Klein- und Mittelstädten
Datengrundlagen: Regionaldatenbank der Statistischen Ämter des Bundes und der Länder, Tab. 12411-02-03-4 (Abruf 15.04.2020), BBSR, IHK Hannover, IHK Karlsruhe, eig. Berechnungen. * Bevölkerungsgewichteter Mittelwert der jeweiligen Landkreise und kreisfreien Städte im Untersuchungsgebiet.		

Tab. 1: Eckdaten der Untersuchungsgebiete.

3.3 Konsumentenbefragung

Für die Befragung wurde eine schriftlich-postalische Kontaktaufnahme gewählt, um die Verzerrungsrisiken anderer Befragungsformen zu umgehen. Um den Teilnahmeanreiz für Jüngere zu erhöhen, wurde den Befragten die Möglichkeit eröffnet, den Fragebogen stattdessen online auszufüllen. Die Adressen für die

Befragung wurden von den kommunalen Meldebehörden beschafft. Hierbei wurde eine Zufallsstichprobe aus allen Einwohnern des jeweiligen Gebietes ab einem Alter von 15 Jahren (=Grundgesamtheit) gezogen. Die Befragung fand von März bis Juni 2019 statt.

Der Fragebogen beinhaltete folgende Bereiche:

- Abfrage der letzten drei Einkäufe in den vier betrachteten Sortimentsbereichen (Lebensmittel, Bekleidung, Elektroartikel, Möbel) inkl. der zugehörigen Ausgaben bei jedem dieser Einkäufe. Diese Frageform lehnt sich an vorherige Studien an und dient einer möglichst unverzerrten Abfrage des realen Einkaufsverhaltens (Steiger, 2017; Wieland, 2015; 2019a).
- 15 Einstellungs-Items zur Ableitung der „Online-Affinität" (u.a. Risikoaversion beim Onlinekauf, ethisch-moralische sowie datenschutzbezogene Aspekte des Onlinehandels). Von diesen Items sind neun einem Stated-choice-Befragungsexperiment zur Kanalwahl von Schmid/Axhausen (2019) entlehnt. Diese Untersuchung bildete eines der Vorbilder für die hiesige Studie. Ein weiteres Item bezog sich auf die Informationsbeschaffung über das Internet und zwei auf ethisch-moralische Fragen des Onlinekaufs, die auf aktuelle mediale/gesellschaftliche Diskussionen abzielen, nämlich Umweltbelastung (durch Lieferverkehr) und schlechtere Arbeitsbedingungen (insb. Logistiksektor) durch den Onlinehandel. Drei weitere Items beschäftigten sich mit dem Vertrauen gegenüber dem Internet bezüglich des Datenschutzes und sind aus einer Befragung zu diesem Thema (Sinus 2018) übernommen worden. Dieser Teilbereich wurde aufgenommen, da dem Thema Datenschutz im Zuge des Inkrafttretens der DSGVO (2018) eine erhöhte mediale Aufmerksamkeit gewidmet wurde und die Ergebnisse der genannten Sinus-Studie eine erhöhte diesbezügliche Sensibilität aufzeigen.
- Sozio-demographische Angaben (Alterskategorie, Geschlecht, Berufstätigkeit usw.)

Insgesamt (Ersterhebung und Nachfassung) gingen von 9.120 kontaktierten Personen 1.375 Antworten ein (Südniedersachsen: 297, Mittlerer Oberrhein: 1.078). Dies entspricht einer Rücklaufquote von 15,7 % bzw. einem Promille (0,1 %) der Grundgesamtheit. Von den befragten Personen haben sich rd. 10,2 % für die Online-Ausfüllung des Fragebogens entschieden.

3.4 Erfassung/Kartierung des Einzelhandelsangebotes

Die untersuchungsrelevanten Anbieter umfassen 1) sämtliche stationären Einzelhandelsbetriebe in beiden Untersuchungsgebieten, die zu den vier untersuchten Branchen gehören und bestimmte Kriterien der branchenspezifischen Vergleichbarkeit erfüllen und 2) sämtliche Online-Anbieter, auf die dieselben Kriterien zutreffen. Bei den stationären Betrieben wurden u.a. der Standort (Adresse) und die Verkaufsfläche erfasst. Bei den Onlineanbietern wurden u.a. die Lieferbedingungen (Versandkosten, Versanddauer) erhoben. In jedem Fall wurde recherchiert und erfasst, ob eine Cross-Channel-Einbindung des einzelnen Betriebs bzw. der Kette vorliegt. Hierbei wurde erhoben, ob ein integrierter Onlineshop betrieben wird und ob die „click and collect"-Option angeboten wird. Als "integrierter Onlineshop" wurde definiert, dass auf der dem Betrieb zugehörigen Website 1) das Sortiment des Onlineshops und der einzelnen Filialen und 2) die Verfügbarkeit einzelner Produkte in den Filialen und 3) die Filial- und Onlinepreise sowie weitere Produktinformationen abrufbar sind. Die Informationen wurden über die jeweiligen Unternehmens-Websites (Filialsuche) recherchiert. Verkaufsflächenangaben wurden i.d.R. über Anfragen bei den Handelsunternehmen erfragt; in einigen Fällen erfolgte eine manuelle Erfassung vor Ort. Für das zweite Untersuchungsgebiet wurden durch den Regionalverband Mittlerer Oberrhein Rohdaten einer Einzelhandelsvollerfassung zur Verfügung gestellt. Diese Daten wurden aktualisiert (v.a. durch Recherche von Neueröffnungen und Schließungen).

Weiterhin wurde die Artikelzahl der Onlineshops und, soweit möglich, der einzelnen Standorte bzw. Filialen erfasst. In den Fällen, in denen integrierte Onlineshops bestehen, konnte dies durch selbst programmierte Funktionen und Skripte zum automatischen Auslesen von Websites („web scraping") erfolgen, wofür das Paket httr (Wickham, 2019) in R (R Core Team, 2019) genutzt wurde. Da dies jedoch in Ermangelung integrierter Onlineshops nicht bei allen Verkaufsstellen möglich war, wurden fehlende Werte der Artikelzahl mit Hilfe von Regressionsmodellen interpoliert (z.B. bei Elektrofachmärkten und Möbelmärkten), wobei u.a. die (erfasste) Verkaufsflächengröße als Prädiktor genutzt wurde. Im Fall der Lebensmittelmärkte lagen Einzelangaben zu Artikelzahlen für Super- und Verbrauchermärkte vor, aus denen ein kettenspezifischer Durchschnittswert (Artikel pro qm Verkaufsfläche) gebildet und mit diesem die fehlenden Werte der anderen Vollsortimenter geschätzt wurde. Für LM-Discounter lagen Daten zur durchschnittlichen Verkaufsfläche und

Artikelzahl vor, aus denen der o.g. Indikator berechnet und, darauf aufbauend, deren Artikelzahl geschätzt wurde. Die Artikelzahlen der Onlineshops wurde über deren Website ermittelt.

Die Erfassung des Einzelhandelsangebotes erfolgte im Februar/März 2019 und wurde nach Beendingung der Konsumentenbefragung (ab Juni/Juli 2019) erweitert (z.B. um einzelne Anbieter, die außerhalb der Untersuchungsgebiete lokalisiert sind, jedoch aufgrund ihrer Relevanz berücksichtigt werden müssen). In beiden Untersuchungsgebieten in allen vier Branchen wurden 1.141 stationäre Einzelhandelsanbieter und 115 Onlineanbieter erfasst, wobei nicht alle dieser Anbieter untersuchungsrelevant sind.

3.5 Datenweiterverarbeitung

Da die Modellanalyse auf Individualdaten basiert (Konsument, Anbieter), wurden sowohl die Wohnstandorte der Befragten als auch die Standorte der stationären Handelsbetriebe geocodiert. Aus den Rohdaten wurden Interaktionsmatrizen für alle Kombinationen aus den befragten Personen und den berücksichtigten Anbietern erstellt (Wieland, 2015); diese beinhalten die Einkäufe und Ausgaben der befragten Konsumenten bei allen stationären und Online-Anbietern sowie die erklärenden Variablen (s.u.). Eine wichtige Variable in der Modellanalyse, auf die sich auch mehrere Fragestellungen beziehen, ist die Fahrtzeit zwischen den Wohnorten der Kunden und den stationären Anbietern. Diese wurde für alle o.g. Kombinationen mit Hilfe von Abfragen bei der Open Source Routing Machine (OSRM) erfasst und der Interaktionsmatrix angehängt. Als Indikator wurde hierbei die schnellste Route, gemessen als PKW-Fahrtzeit, zu Grunde gelegt. Diese Arbeitsschritte erfolgten in R (R Core Team, 2019) mit dem Paket MCI2 (Wieland, 2019b), das wiederum über die Pakete tmaptools (Tennekes, 2018) und osrm (Giraud, 2019) auf OpenStreetMap-Daten zugreift.

3.6 Modellanalyse des Einkaufsverhaltens

Die statistische Datenanalyse bzw. Modellierung erfolgte mit einem Hurdle-Modell (Mullahy, 1986), einem mikroökonometrischen Modellkonzept, das zu den Zähldatenmodellen gehört und aus zwei Komponenten besteht: Die erste (participation equation) analysiert, ob etwas Bestimmtes getan wird (hier: ob bei einem bestimmten Anbieter eingekauft wird). In der zweiten Komponente (intensity equation) wird untersucht, wie etwas Bestimmtes getan wird, vorausgesetzt, dass bereits entschieden wurde, dies zu tun (hier: Ausgaben bei den Anbietern, die für einen Einkauf ausgesucht wurden). Das Modell wurde konzipiert, um stark schief verteilte abhängige Variablen mit einem hohen Anteil von Null-Werten statistisch korrekt zu analysieren; allerdings steht dahinter auch die implizite Verhaltensannahme eines zweistufigen Entscheidungsprozesses. Das Modell wird mit Hilfe mit der Maximum-Likelihood-Schätzung (ML) parametrisiert (Cameron/Triverdi, 2005; Zeileis et al. 2008). Die Anwendung des Hurdle-Modells zur Modellierung des räumlichen Einkaufsverhaltens lässt sich wie folgt zusammenfassen (Wieland, 2019a):

$$U_{ij} = V_{ij} + \varepsilon_{ij}$$

Der repräsentative Nutzen ist eine lineare Funktion mit erklärenden Variablen (Teilnutzen):

$$V_{ij} = \boldsymbol{x_{ij}}'\boldsymbol{\beta}$$

Das Hurdle-Modell besteht aus zwei Gleichungen, wobei die erste (participation equation; hier: binäres Logit-Modell) die eigentliche Wahlentscheidung modelliert (Kunde *i* kauft bei Anbieter *j* oder nicht). Deren Zielgröße ist die Wahrscheinlichkeit, dass Kunde *i* Anbieter *j* aufsucht (p_{ij}), d.h. dass die Zahl der empirisch erfassten Einkaufssummen, S_{ij}, größer als null ist; sie wird durch den repräsentativen Nutzen erklärt:

$$p_{ij} = Pr\left[S_{ij} > 0|V_{ij}\right] = \frac{e^{V_{ij}}}{1 + e^{V_{ij}}}$$

Eine lineare Interpretation des repräsentativen Nutzens ergibt sich durch die Betrachtung der Logits (Logarithmiertes Verhältnis der Wahrscheinlichkeiten des Eintretens und des Nichteintretens):

$$\ln \frac{p_{ij}}{1 - p_{ij}} = V_{ij}$$

Der zweite Teil des Modells (intensity equation) beinhaltet alle Werte von S_{ij} größer null. Hierfür wird ein linkstrunkiertes Poisson-Modell verwendet; der Poisson-Parameter λ_{ij} entspricht dem Mittelwert von S_{ij}:

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

$$E\left(S_{ij}, S_{ij} > 0 \middle| V_{ij}\right) = \frac{\lambda_{ij}}{1 - e^{-\lambda_{ij}}}$$

Die Linkfunktion des Poisson-Parameters λ_{ij} stellt durch eine loglineare Form einen linearen Zusammenhang mit dem repräsentativen Nutzen her:

$$\ln \lambda_{ij} = V_{ij}$$

Der Erwartungswert des Hürdenmodells ist das Produkt aus der Auswahlwahrscheinlichkeit der participation equation und dem Erwartungswert der intensity equation:

$$E\left(S_{ij} \middle| V_{ij}\right) = \left(Pr\left[S_{ij} > 0 \middle| V_{ij}\right]\right)\left(E\left[S_{ij}, S_{ij} > 0 \middle| V_{ij}\right]\right)$$

Durch die Aufspaltung in eine „ob“- und eine „wie“-Entscheidung ist es möglich, Einflüsse auf die Auswahlwahrscheinlichkeit eines Einzelhandelsanbieters (stationär oder online) getrennt von den dort getätigten Ausgaben zu betrachten. Im vorliegenden Fall werden konsumentenspezifische Eigenschaften zur Erklärung der Kanalwahl (stationär vs. online) herangezogen, zur Erklärung der Einkaufsstättenwahl (d.h. welcher Anbieter) hingegen Anbieterattribute und Transaktionskosten der Einkaufsalternativen. Die Nutzenfunktionen enthalten – je nach berücksichtigter Branche leicht unterschiedlich – folgende erklärende Variablen, die sich v.a. auf kanal- bzw. anbieterspezifische Transaktionskosten sowie psychographische und sozio-demographische Konsumenteneigenschaften beziehen:

- Sortiment: Artikelzahl der einzelnen Anbieter; Anzahl (siehe Kap. 3.4)
- Fahrtzeit (zu stationären Anbietern; bei Online-Anbietern: null); Minuten (siehe Kap. 3.5)
- Liefergebühr und Lieferzeit (bei Online-Anbietern; bei stationären Anbietern: null); EUR bzw. Tage (siehe Kap. 3.4)
- Cross-Channel-Integration: Vorhandensein eines integrierten Online-Shops, Verfügbarkeit des „click and collect“-Services; Dummy-Variablen (siehe Kap. 3.4)
- Konkurrenznähe: Räumliche Nähe (distanzgewichtet) zu konkurrierenden Anbietern; Indikator auf der Grundlage der Hansen-Erreichbarkeit
- „Online-Affinität“ der Konsumenten: Latente Variable, abgeleitet mittels Faktorenanalyse aus 15 Einstellungs-Items, die in der Befragung erfasst wurden (siehe Kap. 3.3)
- Sozio-demographische Eigenschaften der Konsumenten: Altersgruppe, Erwerbstätigkeit, Geschlecht, Wohnort in einer Großstadt; Dummy-Variablen, in der Befragung erfasst (siehe Kap. 3.3)
- Dummy-Variablen für die berücksichtigten Filialunternehmen (z.B. Aldi, Media Markt, IKEA)

Eine Differenzierung zwischen Kanal- und Einkaufsstättenwahl wurde bei den Modellen mit Hilfe einer Dummy-Variable operationalisiert, die anzeigt, ob Anbieter j ein Onlineshop (1) oder ein stationärer Anbieter (0) ist; für diese Dummy-Variable wurden Interaktionsterme mit den Variablen gebildet, die Konsumenteneigenschaften beschreiben (z.B. wohnhaft in Großstadt, Online-Affinität) und deren Koeffizienten interpretiert. Die Kanalwahl wurde nur im ersten Modellteil (Auswahlwahrscheinlichkeit) berücksichtigt. Die erklärenden Variablen zur Beschreibung der Einkaufsalternativen gingen hingegen sowohl in die participation equation als auch die intensity equation ein. Die Berechnung des Hürdenmodells erfolgte in R (R Core Team, 2019) mit dem Paket pscl (Zeileis et al., 2008).

4 AUSGEWÄHLTE ERGEBNISSE

4.1 Marktanteile und Durchschnittsausgaben (Deskriptive Darstellung)

Tabelle 3 zeigt eine deskriptive Darstellung der in der Befragung erfassten Einkäufe für drei Branchen (Lebensmittel, Elektronikartikel, Möbel). Die jeweiligen Anteile des Onlinehandels spiegeln durchaus die existierenden Marktforschungsdaten wieder (z.B. HDE, 2019). Erwartungsgemäß ist der Anteil sowohl der Einkäufe als auch der Ausgaben bei Elektronikartikeln am höchsten (Südniedersachsen: 41,9 bzw. 31,8%; Mittlerer Oberrhein: 43,3 bzw. 38,0%). Es zeigt sich, dass bei Gütern des mittel- und langfristigen Bedarfs die Ausgabenanteile mitunter deutlich unter den Einkaufsanteilen liegen, was sich auch an den geringeren Durchschnittsausgaben zeigt. Dies kann durch Preisunterschiede zwischen Online- und Offline-Anbietern erklärt werden, jedoch auch dadurch, dass der Onlinekanal tendenziell für geringwertigere Anschaffungen genutzt wird. In jedem Fall zeigt sich daran, wie sinnvoll die Anwendung des Hurdle-Modells (siehe Kap. 3.6 bzw. 4.3) ist, da so zwischen Einkaufsentscheidungen und Ausgaben – die bei deskriptiver und aggregierter Betrachtung deutlich unterschiedliche Anteile haben – differenziert werden kann.

Auffällig ist weiterhin, dass sowohl der Einkaufs- als auch der Ausgabenanteil von Online-Anbietern im zweiten Untersuchungsgebiet höher ist als im ersten, was auf regionale Unterschiede in der Online-Affinität hindeutet. Dies ist möglicherweise auch durch demographische Unterschiede zwischen den Gebieten erklärbar. Daran zeigt sich wiederum die Sinnhaftigkeit eines mikroökonometrischen Modellansatzes, der es ermöglicht, individuelle Charakteristika der Konsumenten zu integrieren.

Tab. 3: Erfasste Einkaufs- und Ausgabenanteile nach Branche, Betriebsform und Untersuchungsgebiet

4.2 Online-Affinität der Konsumenten

Da psychographische Merkmale – konkret: die „Online-Affinität" – eine wichtige Rolle in dieser Studie spielen, ist es sinnvoll, sich die Verteilung der einzelnen Einstellungs-Items anzuschauen (siehe Abb. 2). Das erste Item, das sich auf eine Selbsteinschätzung der Häufigkeit der Nutzung des Onlinehandels bezieht („Ich bestelle häufig Produkte auf dem Internet"), ist in den vier Ausprägungen der Likert-Skala nahezu gleich verteilt („trifft zu": 24,4%; „trifft eher zu": 20,4%; „trifft eher nicht zu": 27,1%, „trifft nicht zu": 25,7%). Sehr auffällig ist die hohe Zustimmung zu zwei Items, die sich auf die Rolle des Internets bei der Informationsbeschaffung im Kaufprozess beziehen (Items 6 und 8): 84,3% der Befragten stimmen der Aussage „Das Einkaufen im Internet erleichtert den Vergleich von Preisen und Produkten" vollständig (54,3%) oder eher (30,0%) zu. Allerdings ist dies offenbar nicht auf das Internet als Kaufkanal beschränkt, denn etwa zwei Drittel der Befragten (66,5%) stimmen der Aussage „Egal ob ich im Internet oder im Geschäft kaufe: Vor dem Kauf informiere ich häufig im Internet über die Produkte vergleiche Preise" entweder voll (38,4%) oder eher (28,1%) zu. Diese Relevanz als Informationskanal ist auch vor dem Hintergrund interessant, dass in der Modellanalyse (siehe Kap. 4.3) auch der Effekt der Cross-Channel-Integration von Händlern untersucht wird; denn ein integrierter Onlineshop ermöglicht das Einholen von Vorinformationen, unabhängig davon, ob im jeweiligen Onlineshop oder stationär eingekauft wird. Mehrere Items, die sich entweder auf Datenschutzaspekte (13-15) oder auf ethische Fragen des Onlinehandels beziehen (8 und 9), legen nahe, dass negativen Aspekten des Onlinehandels zumindest bei bekundeten Einstellungen ein großes Gewicht beigemessen wird.

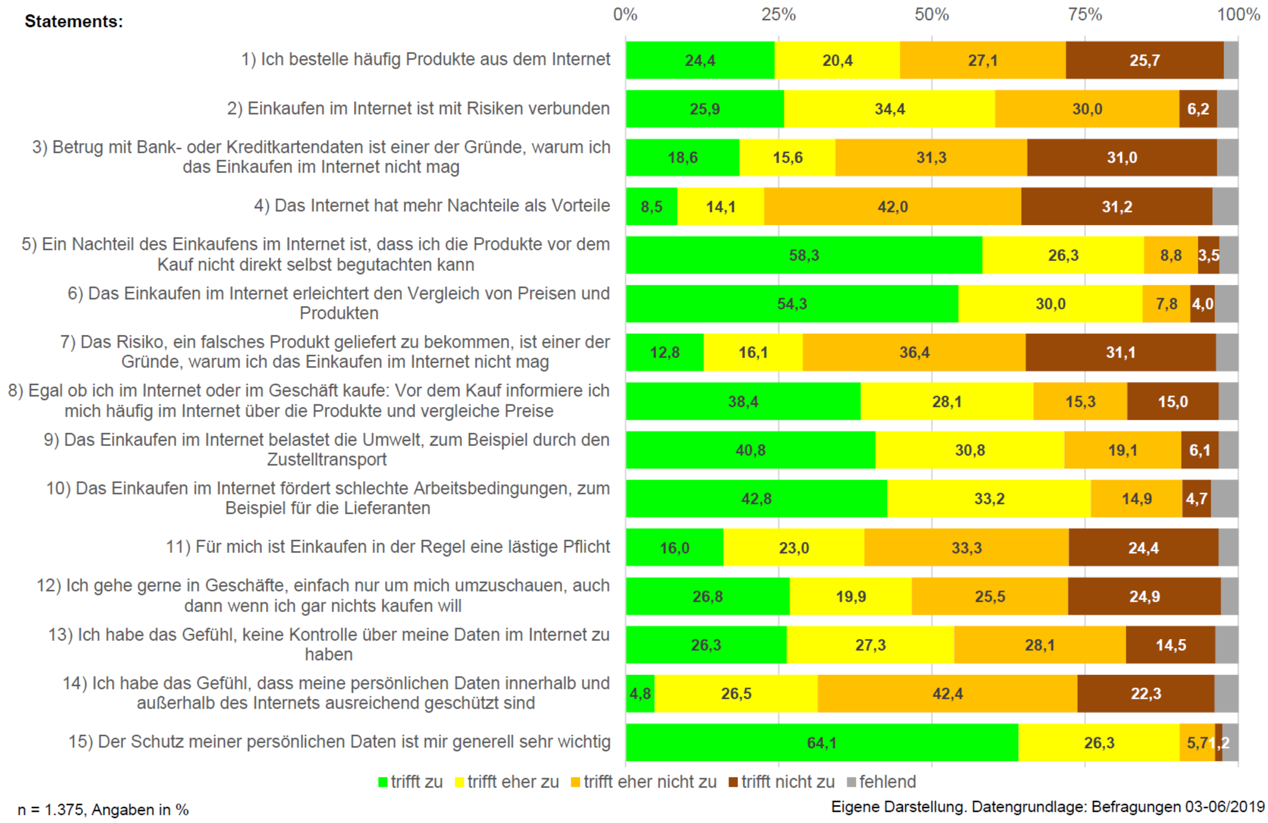

Abb. 2: Relative Häufigkeiten der 15 Items (Quelle: Eigene Erhebungen und Berechnungen).

Die Extraktion von zwei latenten Variablen aus diesen 15 Einstellungs-Items mittels explorativer Faktorenanalyse (Hauptkomponentenanalyse) bestätigt im Wesentlichen die Ergebnisse aus dem Stated-Choice-Befragungsexperiment von Schmid/Axhausen (2019): Die Items 2-5, 7, 9-10 und 13-15 laden in plausibler Weise auf einen Faktor, der im Folgenden als „Online-Affinität" bezeichnet wird (z.B. Item 3 zu Bank-/Kreditkartenbetrug im Internet: Je geringer die Zustimmung, desto „online-affiner"; Item 14 zum Datenschutz: Je geringer die Zustimmung, desto weniger „online-affin"). Eine Reliabilitätsprüfung dieses Konstruktes mit Hilfe des Cronbach's-Alpha-Indikators ergibt einen Wert von $\alpha = 0{,}80$, was einer mindestens akzeptablen, eher guten Reliabilität entspricht. Die zwei extrahierten Faktoren haben einen Anteil der Gesamtvarianz in den 15 Variablen von 37,9%.

4.3 Überblick zu Modellergebnissen

Abbildung 3 zeigt eine schematische Zusammenstellung der wichtigsten Ergebnisse der Modellanalyse für die Branchen Lebensmittel, Elektroartikel und Möbel. Die jeweils ersten beiden Spalten („Kanalwahl: Online" und „Einkaufsstättenwahl") sind die Komponenten der participation equation, sind hier allerdings nach Sinnzusammenhängen getrennt. Ein positiver (grünes Plus) bzw. negativer Effekt (rotes Minus) in der ersten Spalte bedeutet hierbei, dass durch die jeweilige Variable die Wahrscheinlichkeit erhöht bzw. gesenkt wird, online zu kaufen. In der dritten Spalte „Einkaufsausgaben" sind die Ergebnisse der intensity equation zusammengefasst. Nicht in jedem Fall konnten identische Variablen verwendet werden; beispielsweise wurden für Möbelanbieter die Aspekte „integrierter Onlineshop" und „click and collect" zusammengefasst, da faktisch jeder Anbieter mit integriertem Onlineshop auch den zweitgenannten Service anbietet. Die Darstellung differenziert nur in eine (signifikant) positive bzw. (signifikant) negative Wirkung bzw. das Ausbleiben des Nachweises eines signifikanten Effektes. Die Ergebnisse sind nicht in jedem Fall für beide Untersuchungsgebiete identisch und werden in Fällen von Nicht-Übereinstimmung getrennt ausgewiesen.

Im Hinblick auf die Kanalwahl bestätigt sich zunächst, dass eine positive Einstellung dem Onlinehandel gegenüber („Online-Affinität") auch die Wahrscheinlichkeit erhöht, online einzukaufen. Das ist keineswegs so selbstverständlich, wie es zunächst erscheinen mag; denn bekundete Präferenzen sind nicht notwendigerweise kongruent mit tatsächlichem Verhalten (Soziale Erwünschtheit in Befragungssituationen). Ferner basierte die Studie von Schmid/Axhausen (2019), an die das hier gezeigte Vorgehen angelehnt ist, wie viele Kanalwahlstudien, auf einer fiktiven Auswahlsituation; es war somit keinesfalls a priori klar, dass dieses Ergebnis hier anhand von realem Kaufverhalten bestätigt werden würde.

Im Fall der Elektronik- und Möbelkäufe wurde auch der Wohnort der Befragten als erklärende Variable überprüft. Hierbei zeigt sich – überraschenderweise – immer noch dasselbe Muster, wie es in älteren Studien bezüglich der Kanalwahl gefunden wurde, nämlich, dass Großstadtbewohner, alle anderen Bedingungen konstant gelassen, eine höhere Wahrscheinlichkeit des Onlinekaufs haben. Dieses Ergebnis ist deswegen überraschend, weil die höhere Online-Neigung in Großstädten ursprünglich mit der Innovations-Diffusions-Hypothese begründet wurde (siehe Kap. 2); dass Online-Shopping aktuell immer noch eine „Innovation" darstellt, erscheint fragwürdig. Mögliche Erklärungen könnten beispielsweise regionale Disparitäten in der Breitband-Ausstattung oder der Qualität des Mobilfunknetzes (M-Commerce), aber auch eine geringere PKW-Dichte in Großstädten sein; ersteres würde vorranging die Vorinformation und den Einkauf selbst, zweiteres die Erreichbarkeit des stationären Angebotes und den Transport der erworbenen Güter (z.B. Möbel) betreffen. Sozio-demographische Eigenschaften der Konsumenten spielen hingegen nur eine recht geringe Rolle; recht eindeutig (und den Erwartungen entsprechend) ist aber, dass die Online-Wahrscheinlichkeit für Konsumenten ab 65 Jahren geringer ist als für jüngere Altersgruppen.

Abb. 3: Schematische Zusammenfassung von Modellergebnissen nach Branchen (Quelle: Eigene Erhebungen und Berechnungen).

Im Hinblick auf die Einkaufsstättenwahl bestätigen sich zwei Annahmen des klassischen Huff-Modells, hier allerdings unter der Berücksichtigung von stationären und Online-Anbietern: Das Sortiment erhöht die Auswahlwahrscheinlichkeit, während die Fahrtzeit (zu stationären Betrieben) nutzenmindernd wirkt. Dieser Effekt findet sich jedoch nicht in jedem Fall für die Einkaufsausgaben, zumindest nicht bei Gütern des mittel- und langfristigen Bedarfs. Der Sortimentseffekt wurde auch nach Online- und Offline-Anbietern differenziert (hier nicht dargestellt), wobei sich zeigte, dass er bei Onlineshops wesentlich geringer ist; dies lässt sich dadurch erklären, dass Onlineshops i.d.R. ein um ein Vielfaches größeres Sortiment anbieten, was natürlich die Such- und Entscheidungskosten der Konsumenten erhöht. Ein positiver Effekt der Konkurrenzanziehung bei stationären Anbietern (im Sinne von „cumulative attraction") konnte im Regelfall nicht identifiziert werden; im Fall der Einkaufsausgaben zeigt sich eher die Tendenz, dass die räumliche Nähe zu Mitbewerbern die vor Ort getätigten Ausgaben senkt, was auf eine Überlagerung möglicher Agglomerationseffekte durch verstärkten Wettbewerb hindeutet.

Erwartungsgemäß senken steigende Lieferzeiten bzw. -gebühren – aus der Transaktionskosten-Perspektive die Äquivalente zur Fahrtzeit bei stationären Anbietern – die Auswahlwahrscheinlichkeit eines (Online-)

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Anbieters tendenziell; dieses Ergebnis bestätigt ebenso Erkenntnisse aus experimentellen Kanalwahlstudien oder Studien zu einzelnen Multi-Channel-Händlern. Erstmals kann weiterhin nachgewiesen werden, dass die Cross-Channel-Integration von Handelsbetrieben einen positiven Effekt auf ihren Kundenzufluss hat; dies trifft – wie etwa am Elektrofachhandel zu erkennen, bei dem die Cross-Channel-Einbindung auf zwei Variablen aufgeteilt wurde – vorranging auf das Vorhandensein eines integrierten Onlineshops zu; dieses Ergebnis deckt sich mit der in der Befragung festgestellten hohen Relevanz des Internets als Informationsmedium (siehe Kap. 4.2). Der „click and collect“-Service als solcher erweist sich hingegen – zumindest beim Lebensmittel- und Elektrofachhandel – nicht als signifikant nutzensteigernd; dies ist kongruent mit der Erkenntnis aus einer Standortanalyse für Elektrofachmärkte, dass dieses Angebot auch die Umsatzzuflüsse in den reinen Onlinehandel nicht kompensiert (Wieland, 2019c). Der Vollständigkeit halber muss erwähnt werden, dass auch bei Dummy-Variablen, die einzelne Ketten repräsentieren, häufig signifikante Effekte gefunden wurden; dies lässt auf unterschiedliche intrinsische Nutzen bestimmter Marken bzw. Vertriebslinien schließen, liegt jedoch außerhalb der Betrachtung der Studie.

5 SCHLUSSBEMERKUNGEN UND AUSBLICK

Im Zuge des Projektes, das aktuell verlängert bzw. erweitert wird, konnte bislang gezeigt werden, dass es möglich und auch sinnvoll ist, Multi- und Cross-Channel-Einkäufe in ein Modell der Einkaufsstättenwahl zu integrieren, obwohl diese Modellfamilie ursprünglich nur für den stationären Einzelhandel konzipiert war. Weiterhin konnten wesentliche Erklärungsvariablen des Kanal- bzw. Einkaufsstättenwahlverhaltens empirisch identifiziert werden; hierzu zählen insb. anbieter- bzw. kanalspezifische Transaktionskosten sowie objektive und subjektive Konsumenteneigenschaften. Die Ergebnisse demonstrieren, dass die Logik der Standorttheorie des Einzelhandels sowie der früheren Einkaufsstättenwahlmodelle grundsätzlich auf Multi-Channel-Wettbewerbssituationen übertragbar ist; stationäre und Online-Anbieter können – obwohl sie sich in zentralen Aspekten völlig voneinander unterscheiden (insb. durch den physischen Standort, der stets eine zentrale Erklärungsgröße in der Geographischen Handelsforschung ist) – so „vergleichbar gemacht“, ihr Wettbewerbsverhältnis quantitativ abgebildet werden.

Doch auch für die Praxis ergeben sich Implikationen: Modelle der Einkaufsstättenwahl werden seit Jahrzehnten in der betrieblichen Standortplanung und in der Raumordnung eingesetzt, um den Einfluss neuer Angebotsstandorte auf räumliche Kaufkraftströme abzuschätzen (Müller-Hagedorn, 2021); diese Modelle können in ihrem Erklärungsgehalt von der Berücksichtigung des Onlinehandels profitieren und so die Auswirkungen zukünftiger Planungen (z.B. Eröffnungen, Erweiterungen, Verlagerungen) bezüglich Einzelhandelsgroßprojekten zuverlässiger abschätzen. Ein weiterer für die Praxis wichtiger Aspekt ist die Erkenntnis der hohen Relevanz des Internets als Informationsmedium: Die Ergebnisse legen nahe, dass Händler von einer Cross-Channel-Integration in Form höherer Kundenzuflüsse profitieren. Somit zeigt sich Cross-Channel-Vertrieb durchaus als Aspekt der Stärkung bestehender Einzelhandelsstandorte. Da dieser bisher im inhabergeführten stationären Einzelhandel (ISEH) noch vergleichsweise wenig verbreitet ist (Wieland et al., 2020), könnte hier das Citymarketing lokale ISEH-Betreiber beim Aufbau eines solchen Vertriebs unterstützen. Einzelne Initiativen hierzu bestehen bereits, z.B. als Teilprogramm der „Mittelstand 4.0“-Initiative des deutschen Bundeswirtschaftsministeriums.

Es ist jedoch zu berücksichtigen, dass das gesamte Projekt – inklusive der Datenerhebungen, die 2019 stattfanden – die Corona-Pandemiesituation und die damit verbundenen Eindämmungsmaßnahmen („Lockdowns“ usw.) nicht berücksichtigen konnte. Effektiv hat es in den ersten Monaten der Pandemie, teilweise bedingt durch die verordneten Betriebsschließungen, aber auch durch freiwillige Anpassungen des (Einkaufs-)Verhaltens – deutliche Verschiebungen der Marktanteile zu Gunsten des Onlinehandels gegeben (bevh, 2020; Bitkom, 2020). Diesen Aspekten wird in der Fortsetzung des Projektes besondere Beachtung geschenkt, wobei u.a. vergleichende Analysen der Angebots- und Nachfragesituation sowie eine Abfrage von pandemiebedingten Verhaltensänderungen angedacht sind.

6 FÖRDERUNGSHINWEIS UND DANKSAGUNG

Gefördert durch die Deutsche Forschungsgemeinschaft (DFG) – 402130768.

Der Autor dankt den beiden studentischen Hilfskräften Anne Auinger und Anjulie Kappler für ihre Mitarbeit in diesem Projekt (Datenerhebung, -eingabe, und -überprüfung). Dank gebührt zudem mehreren Handelsunternehmen und dem Regionalverband Mittlerer Oberrhein für die Bereitstellung von Daten.

KI-gestützter Wordcloud-Generator für Beteiligungsprozesse

Carsten Oldenburg, Axel Häusler

(MSc. Carsten Oldenburg, Technische Hochschule Ostwestfalen-Lippe, nextPlaceLab, carsten.oldenburg@th-owl.de)
(Prof. Dr. Axel Häusler, Technische Hochschule Ostwestfalen-Lippe, nextPlaceLab, axel.haeusler@th-owl.de)

1 ABSTRACT

Es liegt auf der Hand, dass eine digitale Unterstützung von Planungs- und Beteiligungsverfahren in vielfacher Hinsicht enorme Vorteile bietet. So können mittels moderner, digitaler Partizpationsplattformen Prozessbeteiligte orts- und zeitunabhängig an städtebaulichen Ideenfindungs- und Bewertungsverfahren teilnehmen und ihre Gedanken, Meinungen und Vorschläge mit anderen teilen und diskutieren. Seit einigen Jahren stehen hierfür eine Reihe adaptierbarer Softwareprodukte zur Verfügung, z. B. Consul, ein community-basiertes Opensource-Projekt der Consul Democracy Foundation auf GitHub, die proprietäre Software citizenLab des gleichnamigen belgischen Unternehmens, oder dem neuseeländischen Pendant Loomio der Loomio Cooperative Ltd. und viele weitere. Der webbasierte Zugang ermöglicht dabei nicht nur eine potenzielle Reichweitensteigerung an Teilnehmenden und die schnelle Verlinkung zu anderen digitalen Inhalten bzw. Medien, sondern erleichtert auch die statistische Informationsauswertung und die mediale wie inhaltliche Dokumentation des Gesamtprozesses. Aktuelle Softwarelösungen sind dabei als anwenderfreundliches Baukastensystem konzipiert, das je nach Anwendungsfall individuell, modular und ohne Programmierkenntnisse zusammengesetzt werden kann. Die zuschaltbaren Module reichen von einfachen Formularmasken über interaktive Karten-Tools, MindMaps und Umfragen bis hin zu integrierten Video-Chat-Funktionen und kollaborativen Whiteboards.

Zukünftig ist davon auszugehen, dass die modulare Struktur und die enorm vielfältigen Einsatzgebiete dieser Softwarelösungen zunehmend auch KI-gestützte Funktionen als neue Features enthalten werden bzw. im Baukasten bestehende Module optimieren oder ablösen werden. Die Gründe hierfür liegen größtenteils im disruptiven Fortschritt der Softwarentwicklung. Andererseits darf aber auch erwogen werden, ob nicht doch häufig beobachtete Hemmnisse oder Probleme bisheriger Partizipationsverfahren ggf. durch den unterstützenden Einsatz von KI auch abgebaut oder verringert werden könnten.

Beide Perspektiven stellen für sich genommen schon sehr breite Grundlagenforschungsfelder dar, die insbesondere durch die noch hinzukommenden Aspekte der Technologieakzeptanz enorm komplex werden können. Da aber die technologische Hürde zur Umsetzung einfacher Software-Prototypen durch die Vielzahl zur Verfügung stehender Opensource-Tools sehr niedrig ist, entwickelte der Forschungsschwerpunkt nextPlace der Technischen Hochschule Ostwestfalen-Lippe zunächst eine allererste, prototypische Hardware-Software-Applikation, um - im Sinne eines Proof-of-Concept – die Relevanz und Aufwände tiefergehender Forschungs- und Entwicklungsarbeiten abschätzen zu können. Folglich stellen die nachfolgenden Ausführungen einen technischen Erfahrungsbericht der ersten Entwicklungsschritte dar, um einen einfachen, kostengünstigen und experimentellen Zugang in dieses noch recht junge Forschungsfeld nachvollziehbar zu machen.

Keywords: Data Visualisation, Participation, Speech Recognition, Artificial Intelligence, Internet of Things

2 HINTERGRUND UND MOTIVATION

Wordclouds sind ein bekanntes Werkzeug der Informationsvisualisierung. Sie bieten den Vorteil, dass sich Textinhalte prägnant und zusammenfassend schnell und visuell erfassen lassen. In der Regel begegnet man Wordclouds am Anfang oder Ende von Folien-Präsentationen, um die inhaltliche Bandbreite grafisch darzustellen, die wichtigsten Aspekte der enthaltenen Information hervorzuheben oder einfach als gestalterisches Element in jeglichen Publikationsformen. Ein derartiger Nutzen kann aber auch für, in Präsenz oder digital stattfindenden Workshops oder Besprechungen von Vorteil sein, um aktuelle Diskussionsinhalte für Teilnehmerinnen, Teilnehmer und Außenstehende strukturiert und medial publizierbar widerzuspiegeln. Hierfür wäre es dann allerdings von Vorteil, wenn die Wordcloud einerseits dem Stand der Diskussion in Echtzeit folgen und auch vorhergehende Diskussionstände archivieren könnte, um inhaltliche Redundanzen aufzuzeigen oder ggf. auch Vergleiche zwischen unterschiedlichen Diskussionen herstellen zu können. Damit dies möglich wird, gilt es, die Diskussionsinhalte mehrerer Teilnehmerinnen und Teilnehmer als Tonaufnahme mitzuschneiden und daraus mittels KI-gestützter

Spracherkennung automatisch, in Echtzeit, die wichtigsten Begriffe zu extrahieren und in Form einer digitalen Schlagwortwolke grafisch aufzubereiten.

Technisch gesehen, sind auf der Eingabeseite hierfür einfache Textformate, z. B. Begriffslisten, notwendig, die üblicherweise am häufigsten vorkommenden Schlagwörter vereinen. Neben dem hier beschriebenen Testeinsatz der Spracherkennungs-KI im Rahmen zweier Veranstaltungen gehen die denkbaren Verwendungsmöglichkeiten der Texvisualisierung aber weit darüber hinaus. So unterstützen die Schlagwörter nicht nur externe zugeschaltete oder verspätet eintreffende Teilnehmer beim schnellen Auffassen des aktuellen Diskussionsstands oder der begleitenden Dokumentation, sondern ermöglichen auch zeitliche Veränderungen des Gesprächsablaufs oder temporäre Änderungen der inhaltlichen Prioritäten objektiv messbar zu machen.

In Verbindung mit einer dazu verknüpften, semantischen Netzwerkstruktur ließe sich so, mittels Machine-Learning-Algorithmen, eine koninuierliche Informations- & Wissensstruktur aufbauen, die einerseits durch fortwährende Diskussionsbeiträge wächst und andererseits auch redundante Disksussionsphasen erkennt oder an geeigneter Stelle neue inhaltliche Verknüpfungen oder Inspirationen aus anderen Beteiligungsprozessen einbringen kann. Als allererster Schritt in dieses mächtige Anwendungsfeld wurde in diesem Technologieprojekt zunächst auf experimentelle Weise mit der Verknüpfung einfacher Hardware- und offen verfügbarer Softwarekomponenten begonnen, wobei einschränkend hinzugefügt werden muss, dass eine weitreichende Erprobung und qualitative Bewertung allerdings noch ausstehen.

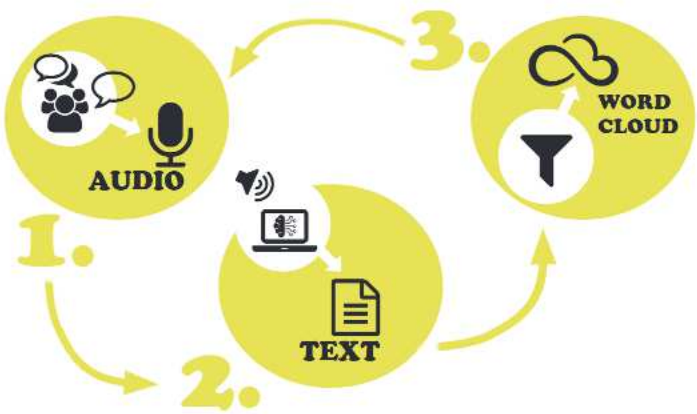

Abb. 1: Grundprinzip der Applikation [Jacobi 2020]

2.1 Stand der technischen Forschung

Erste technisch vergleichbare Konzepte wurden schon vor einigen Jahren u.a. von Haubold (2004) oder auch Flamary et al. (2011) beschrieben. Verwandte Konzepte aus jüngster Zeit finden sich u.a. bei Padmanandam et al. (2021) oder Wu et al. (2020). Bestehende Software-Unternehmen wie IBM, Google oder auch Facebook bieten bereits niederschwellige Zugänge zu intelligenten Spracherkenungssystemen und kombinierbaren Textanalyse-Tools. Das vermutlich prominenteste Beispiel ist die KI-Plattform Watson von IBM, in der die Spracherkennungsfunktionen online als Software-as-a-Service prozessiert werden. Neben diesen proprietären Diensten bietet aber z.B. auch die Mozilla Foundation ein opensource-basiertes Ökosystem zur Spracherkennung und Sprachsynthese mittels diverser Deep-Learning Algorithmen an (vgl. Ardila et al. 2019). Das Projekt ist in sofern von besonderem Interesse, da es im Rahmen der Mozilla-CommonVoice-Kampagne, die Community anregt, ihre eigenen Sprachaufnahmen an ein offenes Repository zu spenden, um die Spracherkenungsbibliotheken fortwährend trainieren zu können.

Prinzipiell ist der Nutzen von Speech-to-Text-Services schon vielfach beschrieben worden und grundsätzlich seit langem erprobt. Der Einsatz im Rahmen von Gruppengesprächen oder Workshops benötigt aber wesentlich performantere Serverkapazitäten, die erst in jüngster Zeit einer breiten Anwenderschicht zur Verfügung stehen. Neuere Konzepte zum Einsatz von Echtzeit-Spracherkennung finden sich daher vornehmlich im Bildungskontext, zur ergänzenden Verständnisunterstützung Beeinträchtigter, wie Google´s Project Euphonia oder auch als Dokumentationsfunktion, gekoppelt an Videokonferenzsysteme, wie beispielsweise innerhalb der Software Zoom.

In Hinblick auf den Einsatz KI-gestützter Verfahren innerhalb öffentlicher Beteiligungsprozesse, lieferte in jüngster Zeit insbesondere auch das Verbundprojekt Civitas Digitalis, der Universitäten Hamburg und Kassel mit der Fortiss GmbH und Stadt Kassel wichtige Erkenntnisse (Balta et al. 2019). Insbesondere konnten hier interessante Grundlagen zur Nutzerakzeptanz digitaler Beteiligungsformate und daraus abgeleitete Handlungsempfehlungen zusammengestellt werden. Allerdings wurde in diesem Projekt durch die Verwendung eines textbasierten Chat-Bots ein verwandter aber etwas anderer technologischer KI-Ansatz gewählt.

3 UMSETZUNG

Im hier beschriebenen Projekt lag der Fokus vor allen Dingen auf einer einfachen Do-It-Yourself-Technologie, möglichst geringem Kostenaufwand und darauf, mittels OpenSource-basierter Software eine erste Schnittstelle zur Nutzbarmachung weiterführender KI-Bausteine herzustellen. Auf technischer Seite wurde ein kostengünstiger Einplatinen-Computer (Rasperry-Pi) verwendet, der die gesprochenen Workshop-Inhalte mittels einer zusätzlich notwendigen Sensorplatine aus acht Mikrofonen (MatrixCreator-Shield) über die GPIO-Schnittstelle (general purpose input/output) aufnimmt. Dies ermöglicht Aufnahmen mit bis zu acht Kanälen. Zu beachten ist allerdings, dass Nebengeräusche und Lärmquellen die Qualität der Aufnahme erheblich reduzieren können. Die Programmierung dieses DIY-Aufnahmegeräts erfolgte durch eigene Skripte auf Basis passender Python-Bibliotheken. Zur Umwandlung der Sprachaufnahmen in Text kam die Open-Source- Spracherkennungsbibliothek Kaldi (Povey et al. 2011) zum Einsatz. Diese Bibliothek bietet umfangreiche Softwarewerkzeuge zur Spracherkennung und Signalverarbeitung.

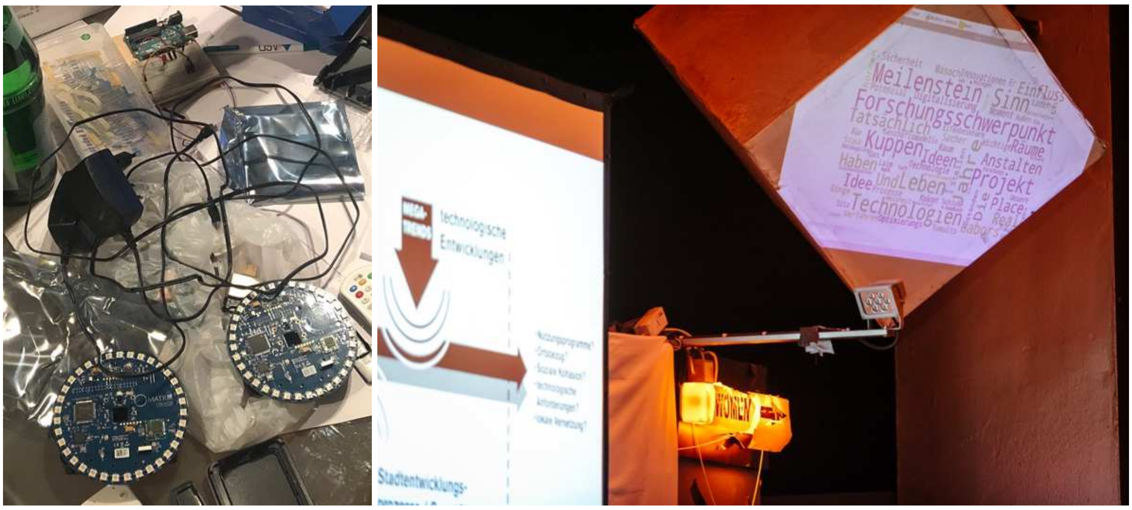

Abb. 2: Bauelemente des DIY-Aufnahmegeräts und Einsatz im Rahmen der Workshop-Veranstaltung 02/2020

Kaldi selbst ist zwar in C++ geschrieben, jedoch ist eine Einbindung in Python durch eine Wrapperbibliothek problemlos möglich. Da es sich bei Kaldi um freie Software handelt, kann diese ohne weitere Kosten auf einem eigenen Server aufgesetzt werden. Dies ist insbesondere datenschutzrechtlich von Vorteil, da auf diesem Wege nicht die Notwendigkeit besteht, Serverinfrastrukturen im Ausland zu verwenden, wie es bei den Cloudtechnologien von Microsoft (Azure) oder IBM (Watson) der Fall wäre. Da die Rechenleistung des Raspberry Pis nicht ausreichend ist für eine zeitnahe Spracherkennung, wird die Spracherkennungssoftware Kaldi unter einem eigens für das Projekt aufgesetzten Linux-Cloudserver betrieben.

Aufgrund beschränkter Performanceressourcen werden die Audioaufnahmen derzeit nicht in unmittelbarer Echtzeit, verarbeitet. Sondern Aufnahmen von 20 Sekunden Länge werden vom Raspberry Pi packetweise an den Kaldi-Server geschickt. Vor der eigentlichen Spracherkennung müssen die Daten noch vorprozessiert werden. Genauer gesagt gilt es, die Audioaufnahmen auf die von Kaldi verwendete Frequenz von 16 kHz herunterzusampeln und die Audiokanäle auf ein Mono-Format zusammenzufassen. Im Anschluss werden die Sprachaufnahmen durch Kaldi prozessiert und die Sprache in Text umgewandelt.

Eine wichtige Limitierung bei diesem Prozess stellt das Sprachmodell dar, dessen Qualität einen hohen Einfluss auf das Ergebnis der Spracherkennung hat. Da es nur sehr wenige, frei verfügbare Modelle für die deutsche Sprache gibt, wurde ein Opensource-Sprachmodell des Fachbereichs Informatik der Universität Hamburg verwendet (Milde, Köhn 2018). Prinzipiell wäre auch die Erzeugung eines eigenen Modells denkbar, allerdings würden hierfür, neben den sehr zeitraubenden Trainingsdurchläufen (viele Tage bis Wochen) auch mehrere hundert Stunden an Basis-Trainingsdaten benötigt werden.

3.1 Schlagwortidentifizierung

Nach erfolgreicher Datenumwandlung in Text besteht jedes Prozesspaket aus mehr oder weniger vollständigen Sätzen, die sich insbesondere durch eine besondere Häufung von nicht-brauchbaren Wortelementen, wie Artikel, Pronomen, Präpositionen, etc. auszeichnen. Mittels eines einfachen Textparsers in Python wurde diese Teile aus den Textdaten eliminiert, um im Anschluss die wichtigsten Hauptwörter abfragen und in das Skript zur Erstellung der WordCloud implementieren und dort nach Häufigkeit gewichten zu können. Im Abstand von 20 Sekunden erzeugte das Skript folglich eine neue, dem letzten Sprachverlauf folgende Wordcloud, die ihrerseits wieder durch Beamerprojektion in den Veranstaltungsraum zuückgespiegelt wurde.

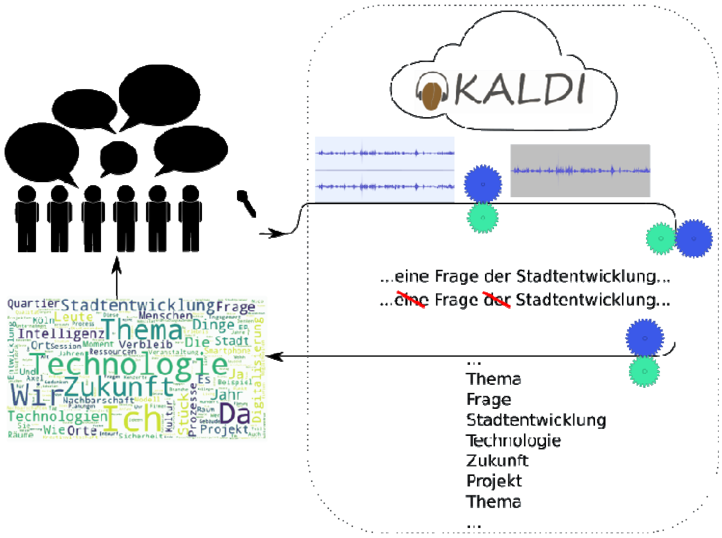

Abb. 3: Schematische Darstellung der Schlagwortidentifizierung und Resultat als Beamerprojektion (eigene Darstellung)

Gleichermaßen wurde in erster rudimentärer Form während Probedurchläufen versucht, thematisch unpassende Begriffe ebenfalls auszusortieren, um die visuelle Informationsdichte der WordCloud möglichst nah am themtischen Schwerpunkt des Veranstaltungsthemas zu halten. Allerdings wurde genau an dieser Stelle relativ schnell klar, dass exakt hier entweder die Grenzen im nutzbringenden Einsatz der Technologie oder die Potenziale zur inhaltlichen Weiterentwicklung liegen. Hierauf soll im Kap.4 noch weiter eingegangen werden.

3.2 Bislang beobachtete Hemmnisse

Während unserer Testworkshops wurden mit der hier beschrieben Konfiguration gleichzeitig die Diskussionen von zwei räumlich getrennten Workshopgruppen aufgezeichnet, um diese später inhaltlich und zeitlich analysieren zu können. Leider stellte sich im Anschluss der Diskussionen heraus, dass die Aufnahmequalität der Sprachaufnahmen mit der Matrix Creator Shield für die weitere Analyse zu schlecht waren und in Folge zu einer sehr geringen Worterkennung resultieren. Folglich eignet sich das hier besprochene Setting für eine einfache Raumaufnahme ohne individuelle Mikrofone nur bedingt.

Für einen weiteren Veranstaltungstermin mit größerer Besucherzahl wurde an dem Raspberry Pi eine externe Soundkarte per USB angeschlossen, die direkt mit dem Mischpult für eingesetzte Funkmikrofone zur Audioaufnahme verbunden wurde. Die direkte Verbindung der Soundkarte mit dem Audiosignal aus dem Veranstaltungsmischpult ermöglichte es, Nebengeräusche weitestgehend zu eliminieren, was wiederum in einer weitaus höheren Worterkennung resultierte.

Derzeit wird die Wordcloud noch auf dem Raspberry Pi generiert. Eine Generierung auf dem Server, der bereits die Spracherkennung durchführt, würde den Raspberry Pi weiter entlasten. Weiterhin wäre es möglich, die Spracherkennung online durchzuführen, d.h. die Audioaufnahmen werden nicht in Paketen mit einer Aufnahmelänge von 20 Sekunden an den Server geschickt, sondern direkt, ohne diese zwischenzuspeichern, an den Server weitergeleitet. Dies würde gewährleisten, dass Wörter während der

Aufnahme nicht auseinandergeschnitten werden und so von der Spracherkennungssoftware nicht korrekt erkannt werden würden.

4 KONTEXTERWEITERUNG

Wie unter 2.1 und 3.1. bereits angedeutet, stellt zwar die reine Spiegelung des kurzfristig Gesagten ein interessantes und kurzweiliges Ergänzungsfeature klassischer Veranstaltungsformate dar. Allerdings muss auch attestiert werden, um mittels Echtzeit-Spracherkennung der Veranstaltung eine neue und inhaltlich weiterführende Informationsebene anzudienen, reicht die rein nach Häufigkeit gewichtete Textanalyse nicht aus. Wesentlich interessanter wäre es, wenn die besprochenen Inhalte in ihrem Kontext automatisch interpretiert bzw. bestimmten (stadtentwicklungs-)methodischen Analyseebenen zugeordnet werden könnten. Folglich muss der bislang reine Textdatensatz um eine gewisse Semantik ergänzt oder in diese eingebettet werden, um in der Lage zu sein, aus den Häufigkeiten bestimmte Bedeutungsattribute abzuleiten und folglich auch wiederkehrende Verknüpfungen in der Diskussion oder Argumentation zu erkennen. Auch wären hierdurch besonders interessante Vergleichsanalysen zwischen verschiedenen Beteiligungsprozessen oder auch unterschiedlichen Stadtentwicklungsdiskussionen denkbar.

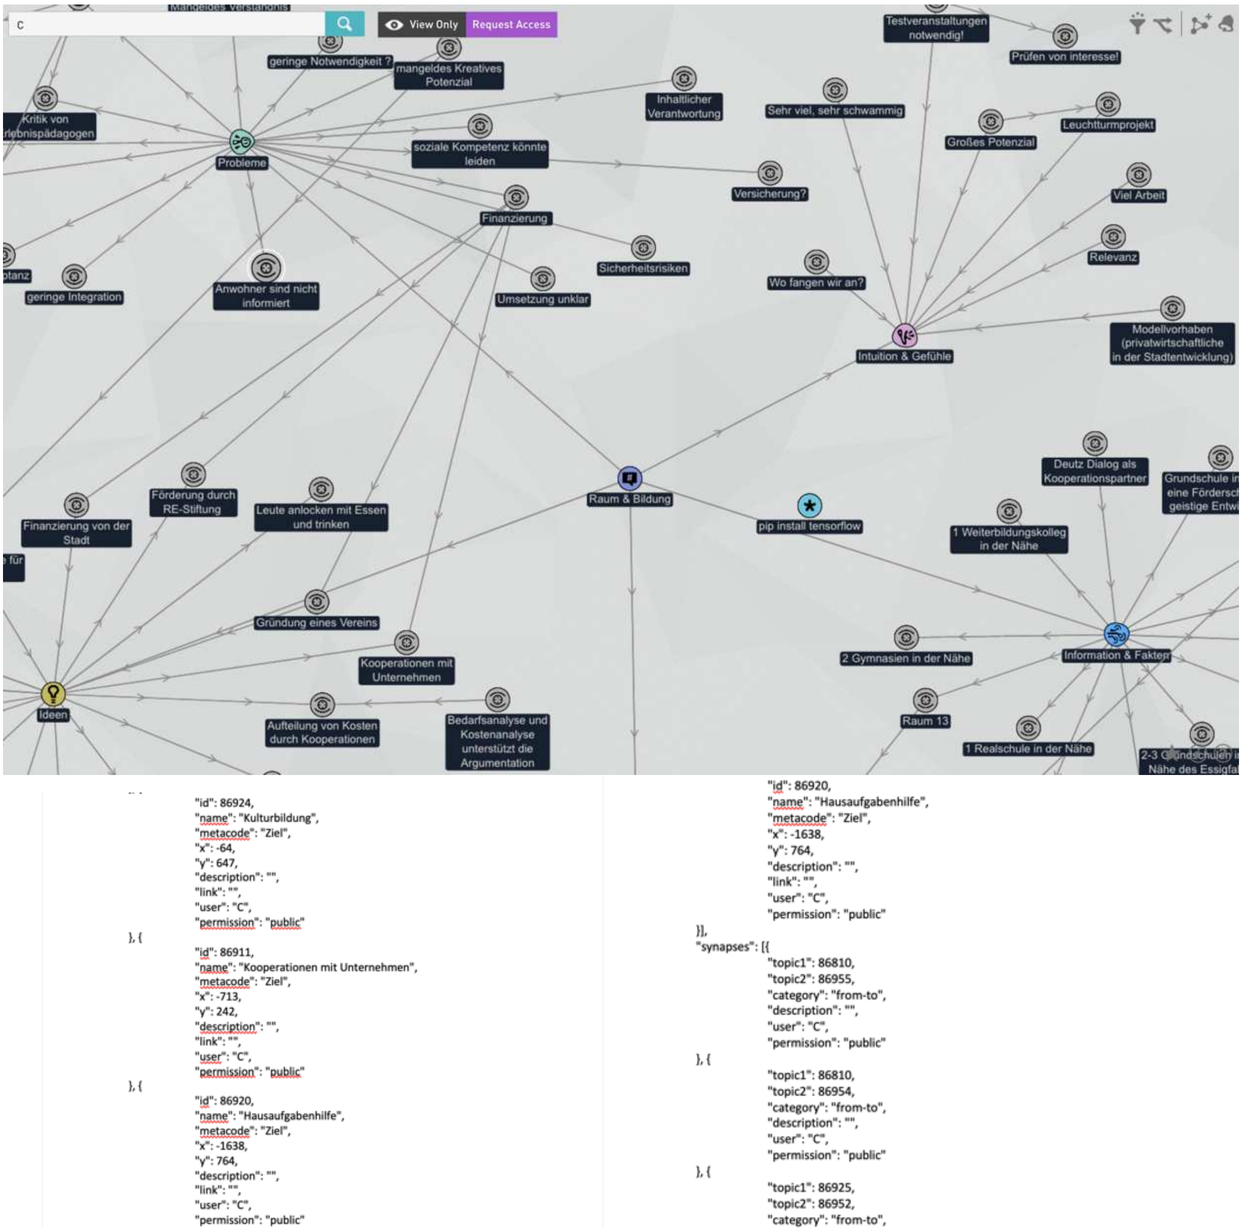

Abb. 4: Visualisierung der interaktiven MindMap und Auszug des Exports im JSON-Format (eigene Darstellung)

Um sich diesem, doch komplexen Thema in einem ersten Schritt nähern zu können, wurden in den gleichen Workshopveranstaltungen, in denen die Sprachaufnahmen als Speech-to-Wordcloud prozessiert wurden, zunächst interaktiv digitale MindMaps erzeugt, die relevante Begriffe quasi „per Hand“ einer

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

Kontextkategorie zugeordnet haben. Ausgangspunkt dieses sehr rudimentären Kontextmodells bildete das Koordinatensystem der bewährten SWOT-Analyse aus Stärken, Schwächen, Potenzialen und Hemnissen. Um das inhaltliche Interpretationsspektrum des Kontextmodells noch zu erweitern, ergänzten wir die vier Bedeutungskategorien um weitere Kontextrubriken, wie z.B. Idee, Problem, Fakt, gesetzliche Vorgabe, Location, Ressource, Partner, etc.. Zur digital-interaktiven Erstellung der MindMaps kam die freie Software MetaMaps zum Einsatz, mit der sich eine klassifizierte Verknüpfung der diskutierten Inhalte kollaborativ und web-basiert erzeugen lässt. Diese Softwarebibliothek wurde auch deshalb gewählt, da die erstellten MindMaps als JSON-Datei exportiert werden können und damit folglich die Grundlage für ein maschinenlesbares und routingfähiges Knoten-Kanten-Modell darstellen. Dieses wird als Basis für das noch zu erstellende, semantische Netz dienen, mit dem die Sprachinhalte später weiter ausgewertet sollen.

Da sich viele Gesprächsinhalte auch mit konkreten Orten im diskutierten Stadtgebiet beschäftigten, wurde eine zweite, räumlich orientierte Kontextebene als kartografische Verknüpfung relevanter Orte hinzugefügt. Auf einem großen TouchTable wurde die kollaborative, auf den Softwareframeworks Django und Leaflet basierende Python/JavaScript-Bibliothek uMap, die eine einfache, der MindMap-ähnliche, aber georeferenzierte Zeichnung von Verbindungslinien zwischen relevanten Kartenpositionen ermöglicht. Die so erzeugten Geodaten können ebenfalls mit zusätzlichen Attributen verknüpft werden und wiederum im JSON-Format abgespeichert und exportiert werden.

Abb. 5: Diskussion der räumlichen Wechselwirkungen via WebMapping-Tool auf dem Touchscreen

Im weiteren Verlauf gilt es nun die beiden JSON-Datensätze durch ein geeinetes Feature-Schema inhaltlich und datentechnisch so zu verknüpfen, dass damit ein routing-fähiges Knoten-Kanten-Netz aus relevanten, wiederkehrend Bedeutungskategorien, einschließlich einer ersten Verbindungsstruktur erzeugt werden kann. Diese Arbeiten, einschließlich der Generierung des semantischen bis neuronalen Netzwerks und der automatisierten Abfrage der Begriffe aus der Spracherkennung sind allerdings noch gänzlich zu erbringen.

5 AUSBLICK

Der hier beschriebene Prototyp bildet ein Teilprojekt eines mehrjährigen EFRE-Forschungsvorhabens zur Erforschung KI- & AR-gestützter Technologien in Stadtentwicklungsprozessen. Zum aktuellen Zeitpunkt liegen die Komponenten des hier beschriebenen KI-Konzepts nur in prototypischer Form und als unverknüpfte Softwareskripte vor. Im weiteren Verlauf ist vorgesehen, die jeweils analysierten

Schlagworteinhalte so in die künftige Semantik zu implementieren, dass diskutierte Chancen und Risiken verglichen, statistisch analysiert und qualitativ bewertet werden können. Ziel ist es, diskutierte Wechselwirkungen und Verflechtungen städtebaulicher Potenziale und Hemmnisse zu dokumentieren, zu untersuchen und ggf. Scheinargumente oder Self-fulfilling Prophecies frühzeitig durch lernende Vergleichsanalysen erkennen zu können.

Neben den beschriebenen softwaretechnischen Aufgaben sind aber darüber hinaus auch noch wichtige datenschutzrechtliche Rahmenbedingungnen abzuklären und generell der individuelle Umgang von Projektbeteiligten mit der KI oder auch die daran geknüpften Erwartungen zu studieren.

1 ABSTRACT

Geographic Information Systems (GIS) are becoming a more common tool in the practice of urbanism and urban design. Usually, GIS is used to visualize geo-located data to gain inside into the urban fabric, to either plan interventions within it, restructure it, or extend it. One problem for a data-driven planning process with GIS is how to turn the gained data into knowledge to drive a project.

This paper discusses the use of super- and unsupervised machine learning to develop land-use scenarios for a vacant site within the city parameters of Berlin. Unsupervised learning is used to find cluster which shares certain characteristics. This interpretation of the data helps to make more informed decisions.

As an example, for supervised learning, a neural network was trained to develop land-use scenarios fully autonomously. Autonomously generated land-use scenarios are an essential step to bridge the gap between the analysis and the design phase of urban development and enable the use of artificial intelligence in the planning process.

Keywords: Land-Use Scenarios, Urban Design, Neurnal Networks, Machine Learning, GIS

2 INTRODUCTION

The topic of "Big Data" or the handling of a multitude of digital resources in urban planning is a long-standing discussion that first emerged in the course of the "Smart City" movements (Batty 2012a; Batty et al. 2012b). The interaction of different disciplines such as planning but also computer science is essential for this phenomenon. On the other hand, the application of these new technologies also scares off many "old-established" planners, the entry hurdle in the application of these new methods was and is partly very high, administrations were not technologically prepared for this trend. The discussion about who has power over the data and who can and may process it has not stopped at urban planning (Streich 2018). Holistic data collection approaches in the smart city context have always relied on the collection of GIS datasets (Exner 2014). 3D city models, on the other hand, attempted to represent the topology of the city in its three-dimensionality (Döllner et al. 2006) and provided the first platforms for simulations in a three-dimensional urban context (Zeile 2010; Mach and Petschek 2006). With the approach of digital twins - coming from product development, transferred to urban planning (Batty 2018), simulation in the urban context is experiencing a renaissance (Dembski et al. 2019).

Using the possibility of parametric design, form-finding processes can be quickly integrated into urban situations. In König et al. (Koenig et al. 2017), "cognitive design" also uses contextual data such as GIS repositories to create and verify designs. In combination with methods of "artificial intelligence" or the "machine learning" assigned to the domain, various international research groups are trying to enrich novel, design methods with "intelligent" algorithms to make faster (and more transparent) statements about (urban) designs like relational urbanism in their approach for the Baishizhou Shanghai study (Ilaria Di Carlo 2016; Llabres and Rico 2016; Cantrell and Mekies 2018). While others generated the land use pattern with cellular automata such as KPF UI (KPF UI 2019, 2018). But some issues have still not been resolved:

How can the data be interpreted correctly in an urban context? Can planners and programmers go beyond the visual feedback of the single layer and analyse them?

In this contribution, we propose 1) a new method for organising land use plans (semi-)automatically out of urban land use datasets and 2) additionally give an outlook on how typological AI can be used to integrate the implementation of different land-use scenarios into generative urban planning processes.

3 MACHINE LEARNING FOR LAND-USE SCENARIOS

In this section we introduce the notion of "land use" used for us in the context of machine learning - it is solely about how we can use a meaningful approach to classify “use” / “land-use” on an urban district level. Land use represents the link between the land cover and the actions people take in their environment (Di

Gregorio 2005). Therefore in planning, the challenge is to find a suitable link between those two, so that the land is suitable for the actions people take and vice versa. While land use is relevant in different scales like the regional, city, district or quarter and parcel or building scale (Curdes 1995), in the following we will focus on the district scale.

In the following, we consider the search for suitable land use as a classification problem, while classification is assigning objects to a group based on several observed attributes. (Sathya and Abraham 2013)

If we use this logic to identify a suitable land use for a specific area, the object becomes a certain area of land which can be assigned to a group of potential land uses, based on its attributes. Following this approach implies that not merely the intention of the planner – but the characteristic of the land itself becomes the driver for the pursued use. Whereas the use can become the driver of the design itself.

The case study for the use of machine learning for land use scenarios was conducted and discussed for the Berlin Pankower Tor site, a flat conversion area of a former freight station. Both super-supervised and unsupervised machine learning were used to interpret geodata.

3.1 Methodology: Land-Use – from Vector to Grid Cell

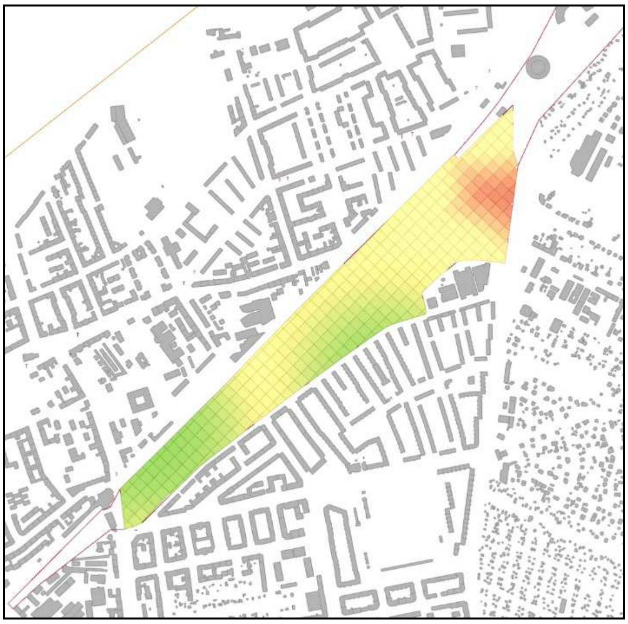
With the help of machine learning algorithms, we aim to go beyond the representation of geospatial data to a (semi-) automated or first interpretation of it. To apply the algorithms, we first have to prepare the geospatial data for it.

Within GIS the form of raster GIS and vector GIS or the mixture of both are commonly used to represent geospatial data (Winter 1998). To link areas as "objects" for classification with geospatial data, the objects need to be geometrically defined. Therefore, we chose a region-based grid GIS approach, in which we divided the site into grid cells.

Afterwards, we scaled the data to make them relatively comparable to each other. So instead of focusing on absolute values, we interpreted the interplay of relative values of certain data categories with the help of two different machine learning algorithms. Thereby we achieved with the unsupervised learning method we achieved different clusters of areas of a site based on the characteristics whereas with the help of a supervised learning method we assigned land use to specific grid cells based on the characteristics of the cell.

3.2 Data

Various data can be linked to the grid cells of the raster GIS. For example, they could be structured according to the order of the city structure in categories like the constructive spatial structure, land use structure, infrastructure, social and economic structures (Streich 2011).



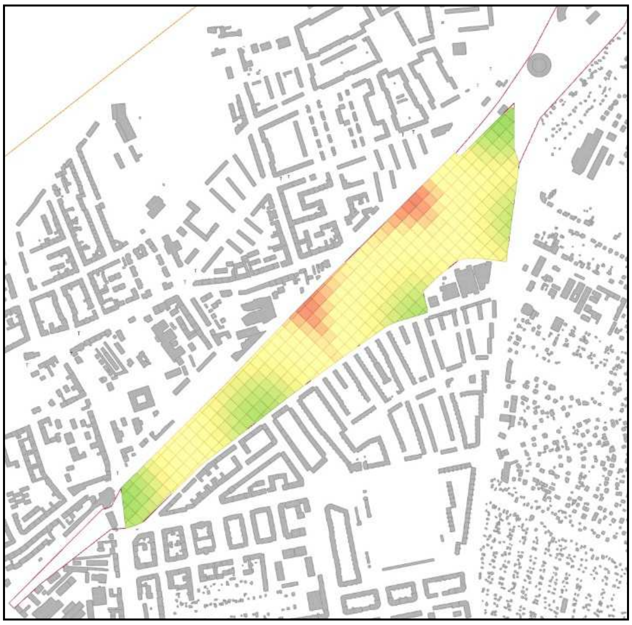


Fig. 1 (left): relative proximity to schools (green high proximity to red low proximity). Fig. 2 (right): relative proximity to public transportation (green high proximity to red low proximity)

The way we implemented geospatial data was by distinguishing distance-based data from environmental and morphological data. If this method would be implemented for analysis of an urban district, other categories such as performance, cadastral and socio-demographic data would matter as well. Distance-based data includes social, cultural or other amenities, local supplies, communal uses, transportation especially public transportation etc. measured in either the shortest or street network distance to the related cell. Environmental data focuses on aspects such as sun exposure, noise pollution ventilation and wind comfort, soil conditions and similar. Less relevant for the case study site as an even and cleared site was morphological data which would include the topology, landscape and existing build structures. Also performance data such as walkability, cadastral data and socio-demographic data didn't play a role in this case. We set a residential mix-use as a specific desire for land use. Therefore, qualitative measures of which land use is best for the site is less relevant. But relative measures like which areas on the site are better for land use x compared to other areas help to place a suitable use. In other words comparing the values of all categories between all cells.

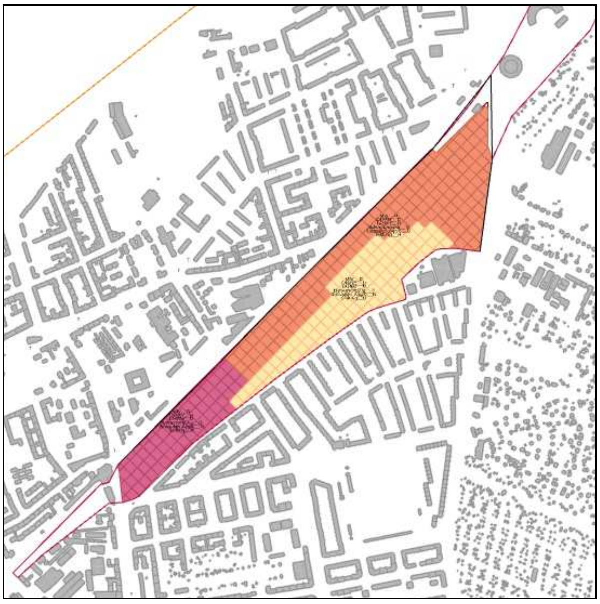
For the task presented in the case study, distance-based and environmental data were the most relevant decision criteria. As an example of distance-based data, we implemented educational facilities (see figure 1), public transport (see figure 2), general accessibility of the site, local amenities, as well as commercial uses based on agglomeration advantages. In the area of environmental data, information on relative noise pollution was used. Therefore we used geospatial data provided by OpenStreetMap (OpenStreetMap Contributors 2020) and the city of Berlin (Senatsverwaltung Berlin 2017).

3.3 Unsupervised and supervised machine learning

To explore the potential of machine learning for land use in the realm of classification, we tested different approaches within machine learning, namely supervised and unsupervised learning.

3.3.1 Unsupervised machine learning for land-use scenarios

As an example, for unsupervised learning, we implemented a k-means clustering algorithm in python with the help of the sklearn library.



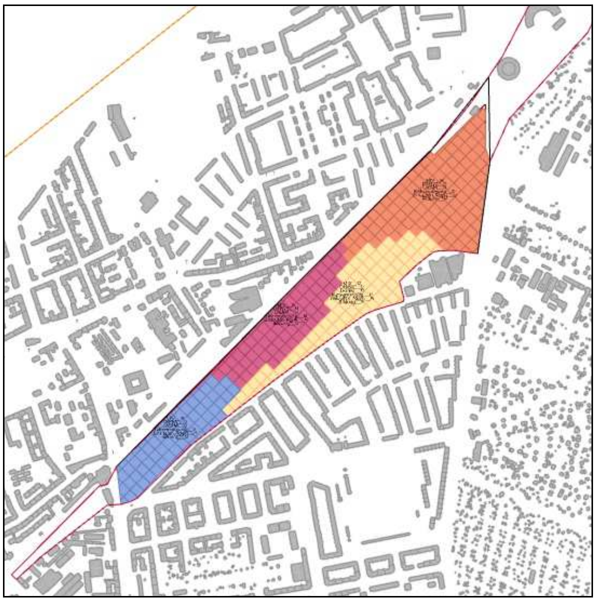


Fig. 3 (left): Clustering with three cluster. Fig. 4 (right): Clustering with four cluster.

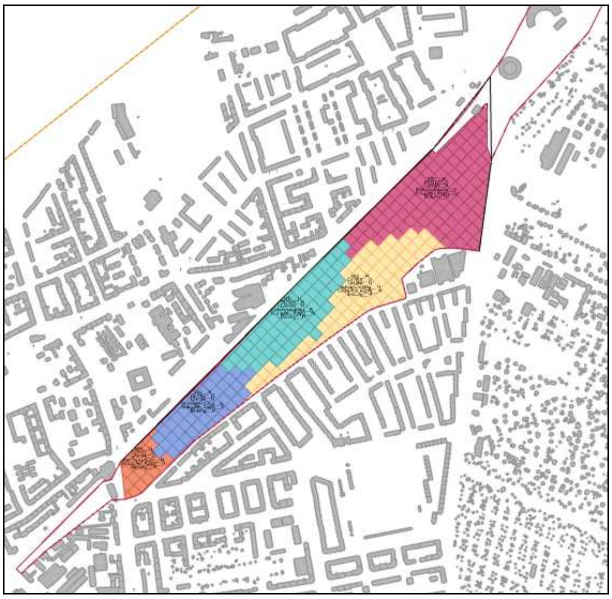
orange	Education demand: high; motorized private transport: high; public transport: average; noise pollution: high; local amenities demand; low; shopping demand:low
red	Education demand: average; motorized private transport: low; public transport: high; noise pollution: average; local amenities demand; average; shopping demand:high
yellow	Education demand: average; motorized private transport: average; public transport: average; noise pollution: low; local amenities demand; high; shopping demand:low

orange	Education demand: high; motorized private transport: high; public transport: average; noise pollution: average; local amenities demand; average; shopping demand:average
red	Education demand: average; motorized private transport: average; public transport: low; noise pollution: high; local amenities demand; low; shopping demand:low
yellow	Education demand: low; motorized private transport: average; public transport: average; noise pollution: low; local amenities demand; high; shopping demand:low
blue	Education demand: low; motorized private transport: low; public transport: average; noise pollution: average; local amenities demand; average; shopping demand:high

Clustering aims to find subsets or clusters within the dataset that are related in terms of their data. The k-means clustering algorithm clusters the data by relating the data points to k sets of clustering centroids (James et al. 2017). This method is best compared to the planner overlaying different analysis layers to search for a pattern that may emerge from it. With the use of the k-means algorithm, this task is automated. The algorithm returns descriptive characteristics for certain clusters of the site. For instance, the description for the yellow cluster in fig. 3 is average values for access to education, motorized private transport, and public transport; low values for noise pollution and high demand for local amenities including a grocery store, while providing relatively low values for shopping. Clustering, therefore, allows to go beyond the visual feedback of a single layer and shows how clusters with similar characteristics emerge on the site. Looking at a different number of clusters helps to get a better grasp of how the site can be organized by relating the values of each cell to one another. This can help the planner make informed decisions while assigning land use. Determining the optimal number of clusters into which the data may be clustered is the popular elbow method (James et al. 2017). In this case, the elbow method suggests five clusters (see fig. 5).



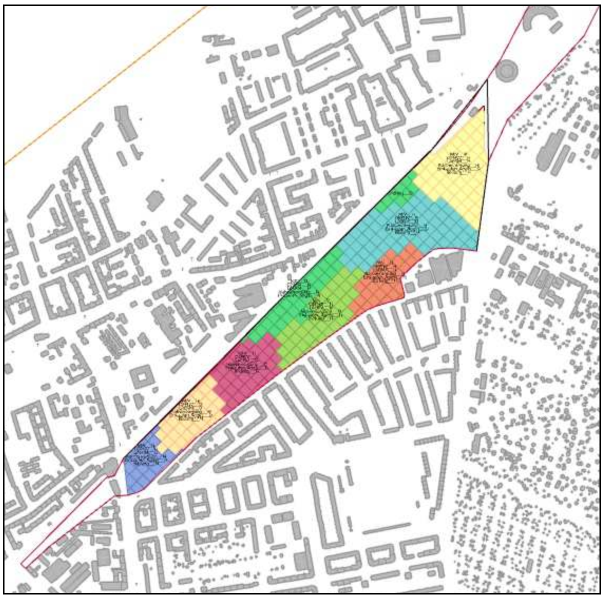


Fig. 5 (left): Clustering with five cluster (optimal acc. to elbow). Fig. 6 (right): Clustering with eight cluster.

orange	Education demand: low; motorized private transport: low; public transport: high; noise pollution: average; local amenities demand; low; shopping demand: high
red	Education demand: high; motorized private transport: high; public transport: average; noise pollution: average; local amenities demand; average; shopping demand: average
yellow	Education demand: low; motorized private transport: high; public transport: average; noise pollution: low; local amenities demand; high; shopping demand: low
blue	Education demand: low; motorized private transport: low; public transport: average; noise pollution: average; local amenities demand; high; shopping demand: average
light blue	Education demand: average; motorized private transport: average; public transport: low; noise pollution: high; local amenities demand; low; shopping demand: low

orange	Education demand: low; motorized private transport: high; public transport: high; noise pollution: low; local amenities demand; high; shopping demand: low
red	Education demand: average; motorized private transport: low; public transport: high; noise pollution: average; local amenities demand; average; shopping demand: average
yellow	Education demand: low; motorized private transport: low; public transport: average; noise pollution: average; local amenities demand; high; shopping demand: low
blue	Education demand: low; motorized private transport: low; public transport: average; noise pollution: average; local amenities demand: low; shopping demand: high
light blue	Education demand: high; motorized private transport: high; public transport: low; noise pollution: average; local amenities demand: high; shopping demand: low
green	Education demand: average; motorized private transport: average; public transport: low; noise pollution: high; local amenities demand: low; shopping demand: low
light green	Education demand: low; motorized private transport: average; public transport: low; noise pollution: low; local amenities demand: average; shopping demand: low
light yellow	Education demand: high; motorized private transport: high; public transport: high; noise pollution: high; local amenities demand; low; shopping demand: low

Since the planner still has to transfer the cluster to meaningful land use himself, this algorithm could be used as a semiautomatic approach, helping the planner to make more informed decisions.

3.3.2 Supervised machine learning for land-use scenarios

The aim of supervised learning differs from the one of unsupervised learning we discussed before. Instead of trying to find clusters on how the site could be organized based on the underlying characteristics, supervised learning relates a specific pre-defined land use to each cell based on how it learned to interpret its data.

So supervised learning depends on a training source with labelled data to train on and to classify the test data accordingly. We used an Artificial Neural Network (ANN) as an example for supervised learning. An ANN uses error signals to adjust its interconnection with weight combinations and thereby learns how to classify cells according to the training data (Sathya and Abraham 2013). We implemented the ANN with the sklearn and tensorflow python library.

Fig. 7 (left): Suggested land use by ANN for the ground floor: 0 – local amenities, grocery, 1 – no specific ground floor use, 2 – commercial (work), 3 – educational amenities, 4 – commercial (retail). Fig. 8 (right): Suggested land use by ANN for upper floors: 0 – residential, 1 – commercial.

As a training set, we generated a pseudo database of land use relating to the categories we use. Therefore, we described each land use how it relates to the categories. For example, a site for a grocery store is described as follows: rather good access to road infrastructure, for better coverage of local supplies a rather high distance to other grocery stores, a medium to high proximity to public transport, proximity to other stores is preferred but not required, proximity to educational facilities, noise pollution or other environmental factors are rather irrelevant. Commonly land use is classified into types such as residential, commercial, industrial, recreational, institutional, various types of green and open space, infrastructural and transportation land use (Reicher 2017). While the method introduced here can be used to assist a classification in such a way, we focused on the usage related to the following planning steps namely educational amenities, local supplies, commercial and residential land use. We differentiated between the use of the ground floor and the upper floors.

Green spaces and infrastructure were considered in a later step. Green spaces and infrastructure were then to the morphology of the urban design rather than to the characteristics of the site itself, even though in a different context, especially green spaces might be more related to the site characteristics and context influences.

In the training process of the ANN, we followed a conventional approach (Hastie et al. 2017). After we trained the ANN and filterd the results, we gained slightly related land-use scenarios for the site which could serve as a base for generating various urban design schemes. In a later stage, we double-checked the average shortest walking distance from each parcel to the amenities in various generated street networks to get feedback on whether it is well-positioned regarding walking distances. The amenities were mostly in their ideal location regarding their walking distance or only off by a parcel.

4 TYPOLOGICAL AI: IMPLEMENTATION OF LANDUSE SCENARIOS FOR GENERATIVE URBAN DESIGN

For a better understanding of what typological AI is and what approaches have been used in the context of urban planning, we start this paragraph by introducing similar approaches.

In addition to the more familiar approaches in architecture, parametric design and generative design have also found their way into urban planning (Fusero et al. 2013). Parametric models, applied for example by Zaha Hadid Architects (Rico 2011; Schumacher 2008) or relational urbanism (Cantrell and Mekies 2018; Ilaria Di Carlo 2016; Llabres and Rico 2016), are used for form-finding, scenario development and optimization of certain aspects of a design (Fusero et al. 2013). Generative approaches like from Nagy et al. represent more or less fully automated design generation to optimize development for profit and solar energy (Nagy et al. 2018). More recently, Design Space Exploration started to be used for multi-criteria and stakeholder optimization in urban design like suggested by Wilson et al. (Wilson et al. 2019, KPF UI 2019;) and implemented also by sidewalk labs and others (Ikhena 2020; Margrave 2020). The proposed method enables the generation of design variants via procedural geometry generation and statistical analysis of the variants. This allows a systematic search for designs based on performance criteria to find reasonably good trade-offs for multiple criteria and multiple stakeholders.

But how can the design space be generated to represent a rather extensive field of possibilities? And how can a generated design relate to its surrounding?

4.1 Methodology: land use to typological design generation

The already discussed ANN land-use scenarios require as input contextual, environmental and other influences as well as desired land-uses. Those land-use scenarios serve as a base for the procedural design generation of variants. The generation of the design variants is built up as follows: first, the structure of the district is generated based on the district typology, based on the construction fields of the district typology building typologies are generated and complete the urban design.

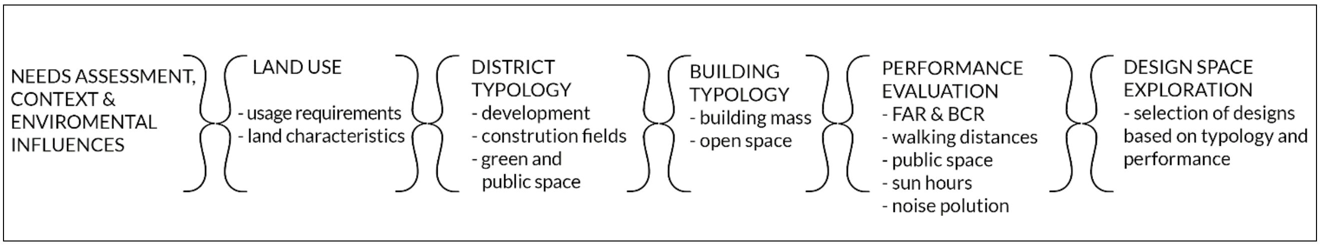

Fig. 9: Proposed workflow

The design versions are evaluated for floor area ratio (FAR) and building coverage ratio (BCR), real walking distances to key amenities, quantities of land usage, sun hours and noise pollution. After the design versions are exported including their performance data, they are imported into a design space explorer (DSE) to make them easily selectable based on their performance values and morphological criteria like the district typology, the building typology and the average building height.

4.1.1 District Typologies

There had been various approaches on how to generate urban design variants. A common way is to start with the street network and then to implement other morphological elements like green spaces and buildings (Schumacher 2008; Rico 2011; Cantrell and Mekies 2018; Fink and Koenig 2019; Wilson et al. 2019). In urban design also other approaches had been discussed, for example, to start with the green and public spaces and then to develop all other aspects according to it (Bott et al. 2014; Sheppard 2015). One of the key benefits of working with DSE is the ability to make different design approaches comparable and include them in the design space in which the planner and stakeholder can search for a suitable design scheme. To offer a design space that incorporates different approaches, we developed typologies for urban districts in the German context. Like building typologies also district typologies can benefit from the "inherent knowledge" (Curdes 1995) of the typology due to the "shared formula" derived from repetitive construction (Luna et al.

2010). The district typology incorporates the street network, construction fields, as well as the public and green space system. Following typologies had been developed, described algorithmically and were implemented in the generative process: the grid district, the irregular grid district, the fluent district, the cluster district, the central district and hybrid forms with the free shaped public space, overriding open spaces and various exceptions.

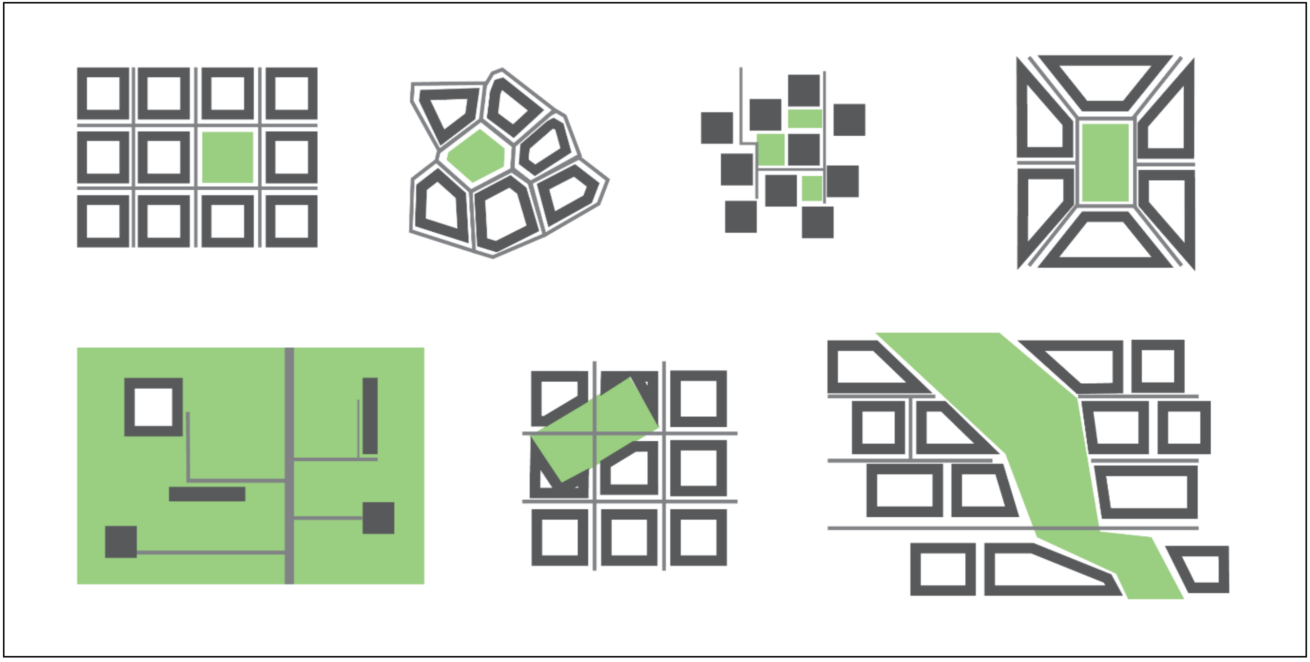

Fig. 10: District typologies: grid district, irregular grid district, cluster district, central district, fluent district, free shaped public space, overriding open spaces.

4.1.2 Building Typologies

Based on the construction fields and the land use, the construction fields are further divided into parcels suiting the land use. Based on the parcels and the land use, different building typologies are generated.

There are various suggestions for typologies on the building level (Bürcklin and Peterek 2016; Reicher 2017; Korda 2005). In this context, we implemented the perimeter block, the dissolved perimeter, linear buildings, detached houses including multifamily, the box and hybrid typologies.

4.1.3 Performance Evaluation and Design Space Exploration

After an urban massing is generated, it is evaluated on different performance criteria. Following the process of geometry generation like shown in figure 11, preliminary urban designs were generated based on the land-use scenarios derived from the Artificial Neural Network, district typologies and building typologies. At the point of the analysis (Fig. 11, 8) over a thousand variants were generated. For each land use scenario (figure 11, 3), the different district typologies (figure 11, 4-5) were applied in certain variants of the typologies, like different orientations or grid sizes etc. Based on the district typologies different building typologies (figure 11, 6-7) were applied again enriching the solution space. These generate urban massings are now calculated in quantities, like area usage of public versus private areas, FAR, BCR etc. and performance characteristics. We implemented a sunlight analysis (Ladybug 2013), real walking distances with a*search algorithm and noise exposure. Many other evaluations could be applied, like cost estimates etc.. But with each evaluation the time required for the computation increases. Based on these criteria, the choice of various typologies and their comparability with help of DSE makes them selectable for various interest groups like investors, cyclist activists, environmental activists, administration and others. We also found with a small study group, that the way the design variants are selectable with the DSE can be used to help also non-professionals to express their desires and priorities for the site based on a preliminary design. This could make this workflow interesting for more interactive participation methods like the Charette (Nanz and Fritsche 2012).

With this heuristic approach based on land use scenarios urban designs could be found, that outperformed an urban design study for the site in all areas (Christ et al. 2017). This means, that versions were found, that

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

provided more open space as well as more build square meters, shorter real walking distances to all key amenities, more sun hours per façade square meter and less noise pollution.

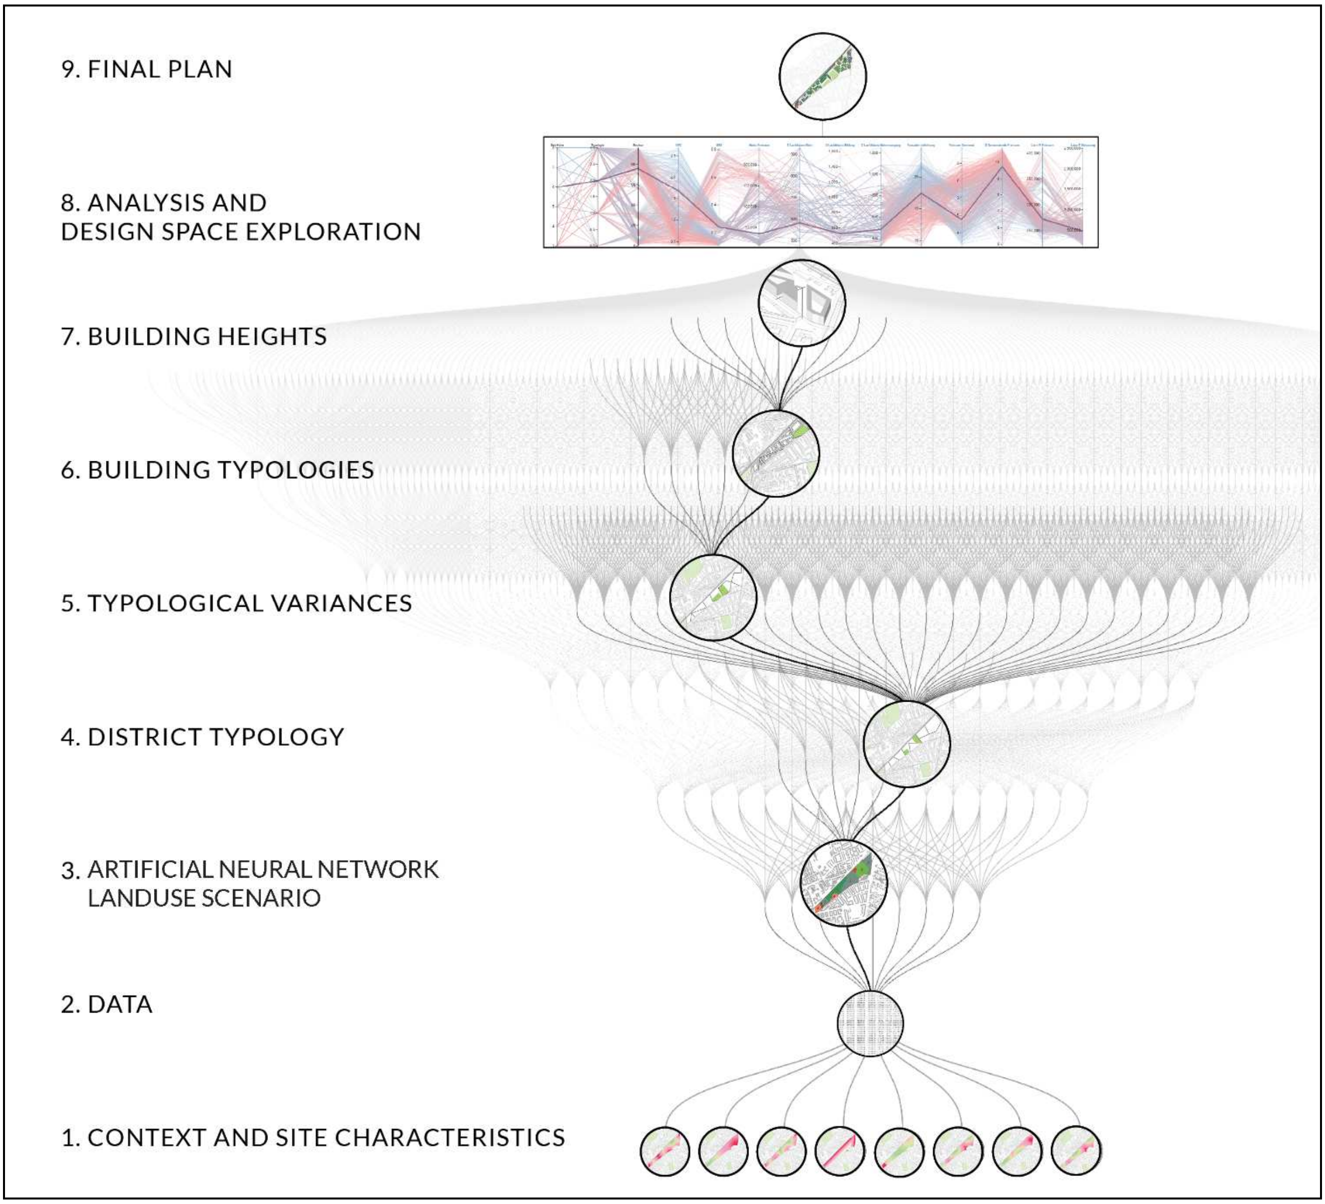

Fig. 11: Integration of the land-use scenarios in a generative typological approach

5 CONCLUSION

While both machine learning algorithms - supervised and unsupervised - aim to find hidden patterns in geospatial data referred to a site the way they do this differs. The fundamental difference between those two classes of machine learning is the existence of labelled training data (Wah and Berry 2020; Alloghani et al. 2020).

In supervised learning, with the existence of labelled training data, the data pattern or characteristics of a grid cell as data are directly transferred to a specific label from the training set in this case a land use. Whereas in unsupervised learning, the hidden pattern in the analysed geospatial data is related to each other as clusters. While the cluster emerge from the characteristics of the geospatial data of each grid cell. This makes each approach suitable for different use scenarios.

The supervised learning method, which was discussed with the example of an Artificial Neural Network for classification, is suitable for directly generating land-use scenarios and use these as a design basis for generative urban design. It comes with the upside of directly performing a task for the planner of placing the land use in a way that suits the labelled training set. This makes supervised learning suitable to at least partially automate the task to develop land-use scenarios.

But the training of the Artificial Neural Network and the description for the land use for generating the training data is a relatively time-consuming matter - especially if the requirements for the land-use change. Also, the ability to control the quantity in which each land use is assigned is rather limited.

Unsupervised learning on the other side does not directly transfer the information of the geospatial data to pre-defined land use or label. It rather provides an analysis of the relationship of the geospatial data, or the analysed characteristics of each cell, to each other. Therefore, it can be used as a helpful tool for analysis to show the planner patterns or better clusters which emerge from different combinations of geospatial data.

This approach is rather flexible and relatively easy to implement and can give the planner a first overview and inform the decision of where to place which use. The performance evaluation of the generated preliminary design based on the land-use scenarios shows that this method can help to find high-performance designs (s. 4.1.3) and especially DSE makes these design variants comparable and selectable based on structural or performance criteria.

In general, the presented AI mechanisms in combination with the design space exploration fits very well in the context of urban workshops, initial brainstorming, starting discussions and the first approaches with quantitative data to an area and the spatial grasping of the proposed uses and dimensions. It is intended to be a useful addition to the planning process at a very early stage - in the so-called preliminary draft, in which important urban planning parameters are set and checked for their effect. The tool still needs to be tested in real life situations to further evaluate the effectiveness for planning and participation.

The proposed concept is not intended to replace the actual planning work in the sense of plan elaboration and plan realization; rather, we see it as a useful addition to be able to "explore" variants more quickly, better and more transparently and to be able to better grasp not only qualitative design work but also quantitative urban development designs. Used sensibly, it helps to be able to quickly examine variants at an early stage. Artificial intelligence is not intended to replace the planner's profession, but to better prepare the basis for decision-making.

1 ABSTRACT

“The Flemish territory is characterized by a large urban sprawl […]. Even last years, an additional 6 hectares of undeveloped space is being built on daily. As a consequence open space is highly fragmented in Flanders“ (Pennincx, De Maeyer, Leroy, & De Mulder, 2021). As a strategic objective, the Flemish spatial government aims at a transition towards a net zero landtake daily by 2040. In this context, our spatial economy research group takes the choices and behaviour of individual companies and their use of space as a starting point. The main goal of the research is informing policy and supporting decision making by discerning spatial patterns, related to economic locations, and more precisely by focusing on the spatial environment of these locations.

Over the years, we developed a the business-oriented approach for local spatial-economic policy and location advice for companies (Giaretta, Zaman, Pennincx, & De Mulder, 2019; Zaman, Pennincx, & De Mulder, 2020). For this, we need the exact location of the activity and the exact activity of every economic site. However,this information is difficult to gather from the only area-wide economic administrative database for the whole territory of Flanders (VKBO) (Gruijthuijsen et al., 2018). This area-covering database is used for major spatial-economic analyses, but it falls short in precision at the detail level needed for our work. We have carried out quite a lot of research in recent years to get to know the terrain situation by creating a field inventory. A key element of the research is the search for the right spatial synthesis of the data collected at the level of the parcel: through economic ecotopes and market segments we sought to combine the (economic) parcels into meaningful groups with similar characteristics. We described this step in previous papers (Giaretta et al., 2019; Zaman et al., 2020).

Although the past research is interesting for the local policy makers of the mapped area’s, we still need to find a way to also make meaningful statements on spatial economic patterns for other areas in Flanders that have not been mapped. Producing this area-covering map for Flanders is rather important, as it will enable us to translate the analyses and the knowlegde we have gathered to (regional) policy. Although being thourough and rather precise, the visual inventory method has some drawbacks: it is time consuming and at this point, it cannot be easily applied to the entire area of Flanders. We therefore opt to first assess if we can extract useful statements regarding economic patterns from administrative databases.

The main research question is whether the synthesis of the mapping data into the economic ecosystems or economic segments can be reproduced with the administrative database. Obviously, the results from the administrative database and the inventory will not be 100% alike. However, we believe it is possible come to spatial economic meaningful groups, even using the administrative database. The purpose of this grouping remains the same as with the inventory work and economic ecotopes and segments: being able to inform policy choices related to economic locations.

In a first step, we examined whether and how the area synthesis (starting from the inventory and resulting into economic ecotopes and segments), that was carried out with manual work, field knowledge and expert opinion can be reproduced through automated methods, specifically through (1) statistical approach and/or machine learning and (2) a spatial predefined spatial clustering. The automated grouping results are reviewed and spatially analysed by spatial planners with territory knowledge. Only in a second step, when the grouping results on basis of the inventory are satisfying, we will rerun the method with the administrative data of the VKBO. In this paper we will discuss the first few steps of the grouping methods, in particular the distance and the activities clustering. We will outline the next steps, using the VKBO-data, assessing if we can come to meaningful economic clusters.

Keywords: machine learning, clustering, Spatial economic patterns, Business Perspective, Flanders

2 RESEARCH ISSUE/INTRODUCTION

In a more general way, we aim at informing policy choices regarding economic locations and the spatial environment of these locations. We therefore chose to investigate the microscale first, in order to then arrive at the mesoscale. Next, we are looking for ways to extend the mesoscale to similar areas in Flanders. To this end, we have two main sources of information: a visual field inventory, covering 3% of the entire Flemish area, and an economic administrative database that covers the entire Flemish area.

The first steps of micro- and mesoscale has been to focus on the organisation of economic activities and spatial patterns in Flanders. One part is the categorisation of economic units and parcels, that were observed in the field, into economic ecotopes and market segments of economic spaces. This categorisation is meant to advise companies and policies of the right location for economic activities: is the type of economic ecotope the one that is best suited to the companies' needs, located in that economic ecotope? Which territorial policies can close the gap between the companies' needs and current economic ecotope? (Zaman et al., 2020)

As the current administrative database for the registration of economic activities (VKBO), was mainly designed for legal purposes (and not spacial identification purposes), the exact location of the activity and the exact activity (many businesses register as many activities as possible) is difficult to extract from the database. A visual check between the exact registered location in VKBO and the reality on the field shows us a dicrepancy, that varies according the type of environment (Gruijthuijsen et al., 2018). Therefore, we have been visually recording economic activities on the field since 2017, trying to understand the spatial-economic patterns (for the method see (Giaretta, Pennincx, De Mulder, & Zaman, 2018; Giaretta & Zaman, 2017; Giaretta et al., 2019; Zaman et al., 2020). In november 2019, we had mapped an area of almost 38.000 ha in Flanders and Brussels including almost 45.000 economic activities on 34.000 parcels. This led us to the creation of 16 types of economic ecotopes (Zaman et al., 2020). These are economic environments, taking into account the mix of economic activity and the distance between economic activities.

Although the past research is interesting for the local policy makers of the mapped area's, we still need to find a way to also make meaningful statements for other areas in Flanders that have not been mapped. A considerable area was inventoried with a big difference in types of spaces. However, we want to be able to extrapolate the findings to the whole Flemish territory. Producing this area-covering map for Flanders is rather important, as it will enable us to translate the analyses and the knowlegde we have gathered to (regional) policy. Last, but not least, as researchers in the Flemish government we want to generate research that is consistent for the whole territory. For the time being, there are two possibilities to make this switch to the Flemish scale level: an area-wide inventory of the economic use of the parcels or resorting to the administrative data sources. Although being thourough and rather precise, the visual inventory method has some drawbacks: it is time consuming and should ideally be done once a year to capture changes, as companies come and go, move to another location, expand (or decrease) their activities and so on. The first field work dates from 2016 and it is very likely that it is outdated for some economic locations. At this point, a field inventory of the entirel Flemish area cannot be easily applied: according to the distribution of competences of the different administrations, the source data of economic information for the entire Flemish territory fall under economic administrations, not under those of spatial planning and environment. Before resorting to a field inventory of the entire Flemish area, we want to asses if we can get any useful results from the administrative database: what type of statements regarding the spatial economic patterns can we extract?

The aim is to create spacial meaningful groups of economic activities, that can be reproduced later on, with each new release of the administrative databases. Of course, the results of this automated grouping will not be exactly equal to the 16 types of economic ecotopes, as the visual and automatic methods are too different. However, both start from the visual inventory of economic activities.

3 THE SEMI-AUTOMATED APPROACH TO OVERCOME AN EXPERT-BIAS

In the visual construction of the area types (starting from the inventory of economic parcels into 16 types of economic area's/ecotopes), the researcher used a semi-automatic approach (Giaretta & Zaman, 2017). The previous attempts, made by experts to group the economic parcels, were based on a purely visual interpretation and revealed a considerable expert bias (Gruijthuijsen et al., 2018). A first pitfall was splitting the mapped territory into traditional spatial entities such as "industrial park", "city centre", "main road",…, whereas the mapping of economic activities clearly did not stop at the pre-defined borders. The inventory showed for instance quite an amount of productive activities in the mixed fabric of certain areas, which went against the expectations of experts, who tend to see mixed environments only suitable for retail and offices, and industrial parks as the exclusive location for productive and wholesale activities. As a consequence, productive and wholesale activities were not taken into account or acknowledged in mixed environments, according to the expert-based economic area types. In order to overcome these biases, we objectified the occurrence of economic activities into groups, and later interpreted them again.

This method consists of three main steps. First of all, the parcels with economic activities are divided into classes based on distance from each other (0m, 20m, 50m, 90 m) (ArcGIS near tool). Each parcel with an economic use gets an additional attribute field containing the distance to the nearest other parcel with an economic use. This produces a map of parcels with an economic use, grouped by distance. The second step of the operation was to use this map as an indication for drawing polygons based on the key paterns, e.g. distance, density, local field characteristics, grouping the different polygons into three new types. A first group, concerned the merging the neighbouring polygons with a continuous occurrence of economic activities. The second new group consisted of the nearby polygons with less continuous economic activities and even including small clusters of continuous economic activities. The third new area category regrouped the rest of the mapped area, in which economic activities are spread out and fragmented. It is important to note that in this fase of manual drawing, the researcher ¬–who was a spatial expert– applied his knowledge of physical spatial boundaries such as recognising main streets and entrances to back streets, streets with different width, zones for loading and unloading, etc... or spatial appearance such as building typology, presence of greenery or pavements, etc. In the third and last step, in order to define homogeneous areas of similar economic composition, these areas were again subdivided using the presence of different economic activities. A continuous economic area (e.g. along a main road) where one section is mainly retail, and another section has also productive activities would be split in two, to create two distinct, more homogenous types. In this step, the parcel map was initially interpreted visually. In our 2020 paper we explored the types more in depth (Zaman et al., 2020). Again, terrain characteristics were taken into account by the researcher-expert.

The method resulted into a classification of 16 types of economic ecotopes) (Zaman et al., 2020). These are economic environments, taking into account the mix of economic activities and the distance between them.

4 AUTOMATED CLUSTERING (USING THE INVENTORY OF PARCELS WITH ECONOMIC USE)

Although much of the additional field characteristics and implicit knowlegde used by the planner in the semi-automated method could in theory be available digitally, these data are difficult to identify, interpret and to collect for the research areas and the entire Flemish territory. The automation must therefore replace the expert knowledge with something else that also results in a usable spatial economic classification.

Taking aside the extra information the planner used in order to define the final economic types, the semi-automated method consisted of two 'objectifiable' steps: firstly, clustering the parcels with economic activities into categories based on distance between the parcels with economic use and secondly, when this distance clustering gives a stable and accountable result, analysing what types of activities are collected in the clusters. Finally, this leads to a new homogenous groups, that are relevant from a spatial economic point of view.

The goal of the economic classification is a map, showing spatial economic relevant results, that covers the entire Flemish territory. Eventually it will be based on data available in administrative (economic) datasets (VKBO). We therefore first tested several methods on distance and activities clustering within the mapped area that contains the data of the terrain inventory. Next, we tried to reproduce the methods with the administrative datasets. This will be discussed in point 5. Every automated step was reviewed by spatial planners with terrain knowledge.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

4.1 Distance clustering

We used several methods in order to reproduce these two steps. For the distance clustering we used four different methods: (1) DBSCAN on distance between centroids of parcels, (2) ST_ClusterWithin (3) DBSCAN on GPS routing distance between access points of parcels and (4) Predefined building blocks.

The DBSCAN algorithm is an intuitively quite easy to understand clustering technique. Starting from a random data point, we find out which other data points are within a defined distance (Method 1: 20m, 50, 100, 500, 5000 m and Method 3: ranging from 25 to 250m walking distance between the access points in steps of 25m). For each new data point we then check which other data points are not yet assigned to the cluster and are also within that distance. We repeat this process until there are no more data points in that cluster. Although the method is interesting because it clusters only data points, regardless of the context (cf. biased view of experts in section 3), and because it clusters on both sides of a same road, the randomness of the method has its drawbacks. The algorithm uses both the distance and a minimum number of points to define the core of a cluster. Points that are only reachable from one core point (and not meeting the minimum number of points critirium), are border points. In our data, there are many border points that can be part of different cores, but in reality belong together in one cluster. (Schubert et al., 2017) The DBSCAN clustering seems to jump sometimes to other points, and to forget the continuity of the cluster in other directions. This 'border' condition results in some 'missed' points, that end up in other clusters (See Figure 1). Another problem with DBSCAN is the size of certain parcels. E.g. when we set DBSCAN variable to 25m, as we want to cluster the parcels where the walking distance between access points is 25m or less, neighbouring parcels end up in a different cluster just because they are larger than 25m. However, using a larger walking distance between the access points, such as 100m, tends to smoothen out all differences: everything is put together in one big cluster. Interesting differentiation is then lost (Figure 1, left image). Variants of DBSCAN such as HDBSCAN* work hierarchical and deterministic (McInnes et al., 2017), and will overcome the randomness of the border points, but it remains uncertain whether it will result in accountable spatial clusters.

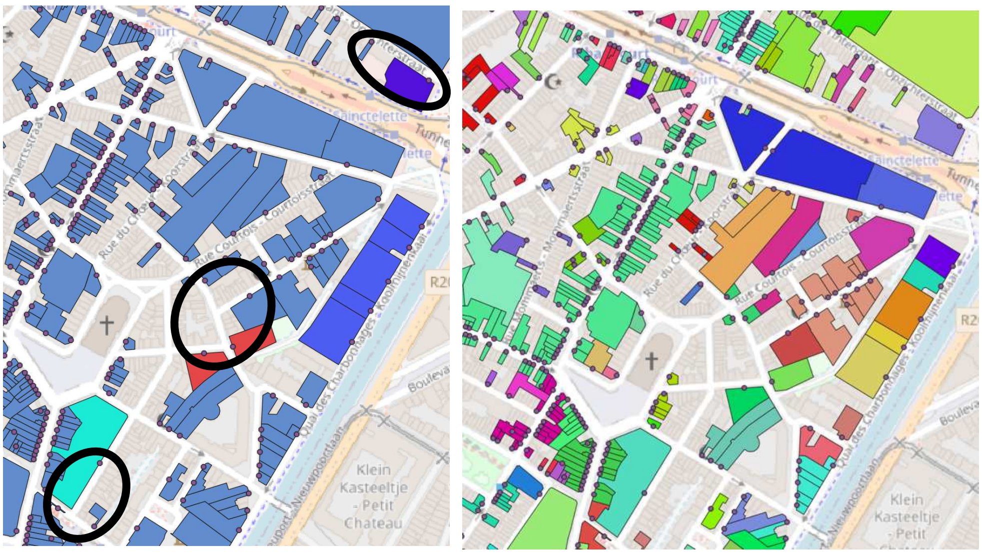

Figure 1 : Distance clusters with DSCAN at 100m (access points) in Brussels centre. Left: some accesses are closer to each other than 100m and yet, are not taken in the same cluster. Right: Distance clusters with DSCAN at 25m (access points): because the parcels are too large, they end up in different clusters, although they are neighbouring. (Background layer: Open Street Map)

The difficulty of dealing with large parcels is mainly due to the reduction of a polygon to a point (centroid or access point). In PostGIS the ST_ClusterWithin function is an aggregate function that returns an array of geometry collections. Each geometry collection represents a set of geometries that are separated by no more than the specified distance (in our case 0,1m, 20m, 90m, 500m). Although this method actually clusters parcels according to a certain distance without randomness, the results show that there are a lot of small clusters, that form a spatial economic point of view should belong together. Next to this, back and front streets are not differentiated.

The fourth method consists of predefining building blocks according to their distance to certain types of roads in OSM[1] (Pedestrian = 25m, Tertiary = 50m in Flanders and 25m in Brussels, Secondary = 70m in Flanders and 50m for Brussels area, Primary = 70m). Only parcels that are within the settlement area are taken into account (Poelmans, Janssen, & Hambsch, 2021), and are categorised according to their distance to pedestrian, tertairy, secondary and primary road.

Figure 2: Distance clusters with ST_Cluster_Within at 0,1m (full colour polygons), 20m (striped polygons) and 100m (dotted polygons). Left: Inner city with primary and secundary shopping street in Roeselare, Flanders: At 0,1m distance, it is logical that roads slice groups that should be together. However, from an spatial economic perspective this does not make sense. Right: A main shopping street in Brussels outer city centre is sliced into several groups. (Background layer: Open Street Map)

After this, parcels are dissolved into building blocks or parts of building blocks. Figure 3 (left) shows the Flemish city of Hasselt that is characterised by two circumferantial roads. The bigger circumferantial one is the main ring road, a primary road, functioning on a regional level (turquoise colour). The smaller one is a secondary road, connecting the regional and local function (blue colour). It surrounds the medieval city centre, that is now mainly a pedestrian area (pink colour). The two ring roads are linked by several secondary roads. The other building blocks that are not within a certain distance from pedestrian, tertairy, secondary and primary roads are the „rest“ category (green colour). The roads around these building blocks have mainly a local function, e.g. connecting residential area's or some parts of business/industrial parks.

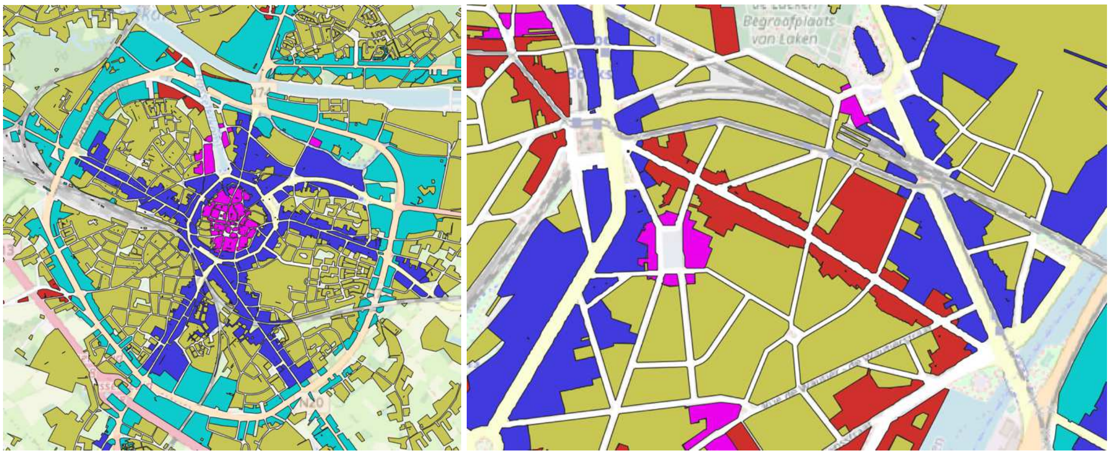

Figure 3: Distance clusters according to predefined building blocks linked to OSM types of roads. Left: the Flemish city of Hasselt and surroundings show that a categorised road network is clearly visible. Right: in the building blocks in the main shopping street in Brussels outer city centre, we distinguish now clearly the main shopping street, as well as the slicing of building blocks, according to back and front streets. (Background layer: Open Street Map)

On the right part of Figure 3, the main shopping street outside the city centre of Brussels, is now clearly defined around a tertiary road (red colour). Because of the predifined distances, the building blocks are as well cut into two parts: a front part, adjacent to the relevant road type, and a back part, that does not have the

1 Open Street Map in Belgium categorises roads into Pedestrian, Motorway, Trunk, Primary, Secondary, Tertiary, Residential, Unclassified, Track, Path, Footway. For our project we assessed that the types Pedestrian, Primary, Secondary and Tertiary were the best suited, as they relate economic locations to accessibility.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

same access and visibility as the front part. The advantage is that we have a spatial clustering that is independent of the presence of economic activities, that has additional attributes linking it to a street name or a street type, and is small. The small size of each cluster combined with the street attributes can allow to merge clusters with the same characteristics in a later stage. It can also prove to be very usefull when we need to add other data (on housing, green, inhabitants,…) to get a better understanding of the differences between types for sit location choice.

4.2 Forming (new) groups through clustering activities

After having a distance clustering, the second general step is to regroup the distance clusters into new groups based on activity mix. The activity combinations in these groups should be internally more or less homogenous, but comparing the groups between each other, they should show enough difference. We used again three methods: (1) Factor analysis (FA), (2) Principal Component Analysis (PCA) and (3) hierarchical manually determined thresholds. A FA is an exploratory data analysis method used to find influential underlying factors or latent variables based on a set of observed variables. It assists in data interpretation by reducing the number of variables. It extracts the maximum common variance from all variables and places them in a common score. The FA was done in promax rotation and 16 factors could be determined. Although quite similar to FA, the PCA is a more robust method and is for instance used in Numerical Ecology (Legendre & Legendre, 2013). PCA is common in exploratory data analysis and predictive modelling. It usually helps reducing dimensionality by projecting each data point only on the first few principal components to obtain low-dimensional data, while preserving as much of the variation of the data as possible. The PCA revealed that certain activities such as Health Care; Education; Vehicle cars/trucks; Arts, Culture, Leisure and Sports; and Vacant are clearly distinguishable from each other. The PCA resulted in 9 groups, where for example Vehicle related activities are mainly in factor 9 (F9), Arts, Culture, Leisure and Sports in F7, and so on.

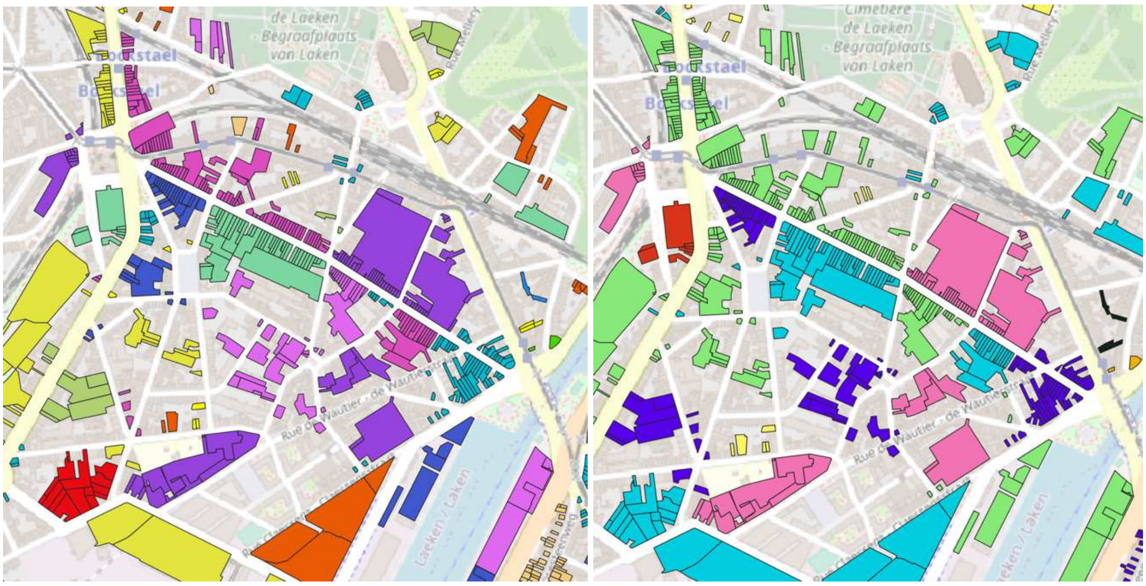

Figure 4: A main shopping street in Brussels outer city centre. Right: Activities clustering with FA – 16 factors. Each colour is another factor. Left: Activities clustering with PCA in 9 factors. The results of both methods are, when compared to terrain knowledge, quite difficult to interpret. (Background layer: Open Street Map)

However, the new formed groups provided by the two activities clustering methods, FA and PCA proved when reviewing and comparing them with in depth terrain knowledge, to be quite difficult to interpret and explain. On one hand, it is not always clear why a type of activity ends up in a certain factor/group, meaning that the differentiation between factors is not clear. On the other hand, there is not always enough differentiation. For example in the PCA, factor 1 (F1) contains more than 50% of all the economic parcels, and is the most mixed factor. It is not clear why a group of parcels belongs to F1, instead of a more „specialised" factor. It contains for instance Vehicle related activities, whereas these activities could also be in F9. In the PCA, activities related to Arts, Culture, Leisure and Sports (ASC) should be grouped in the more „specialised" F7. However, Figure 5 shows this activity is as well in F6. It would make more sense to have these two groups of F6 in either F7 because of the ASC, or in the same factor 1 as the rest of the street, which is the factor with most mixed activities.

The third method of activities clustering has a less statistical background, and is based on defining certain tresholds within the building blocks, in order to come to a spatial economic relevant result. We used the economic typology maps as touchstone and guide.

The categorisation of the building blocks is based on three aspects: (1) using a count of the total parcels in the building block, the propotion of parcels with economic use versus the parcels without economic use, (2) the average distance between the parcels with economic use and (3) using a count of the parcels with economic use, the proportion of the type of economic activities (e.g. services, industry & production, restaurants & bars,…). The first two aspects are quite similar to the semi-automated approach where the parcels with economic use were divided into continuous, close, discontinous and solitary categories. As we start from the fourth method for distance clustering, there are no economic data connected to the clusters. Each distance cluster is joined to the data of the individual parcels with economic uses (type of activity, nearest parcel with economic activity, distance). These are used to calculate density and intensity of economic activities in each cluster. Thresholds are manually set to resemble the results from the semi-automated approach. From the count of economic activities and the proportion of each category of economic activities, the type is further developed with conditional statements. When a certain condition is met (e.g. more than 50% retail) the type is defined regardless of the other values, if not the next condition will be checked. The resulting map of types of economic ecotopes ressembles the manually produced map, but in this case based on a SQL statement.

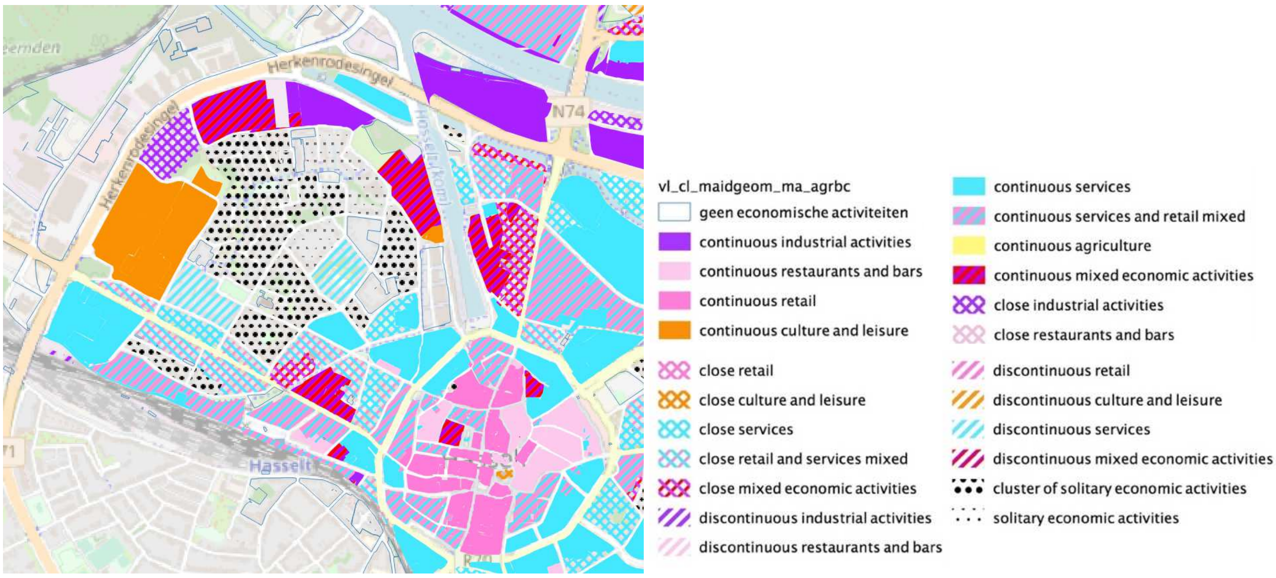

Figure 5: Activities clustering within the predifined building blocks, in the Flemish city of Hasselt. (Background layer: Open Street Map)

Figure 5 shows the results of the clustering in the Flemish city of Hasselt. The economic dense inner medieval centre contains a lot of continuous retail, restaurants and bars, with closer to the small inner circumferential road more continuous services. There are more mixed economy and industrial activities in the vicinity of the bigger circumferential road, which seems logical as there are a couple of regional industrial parks. The secondary road connecting the inner to the outer ring road structures some continuous and close economic activities. The more residential area's accomodate more isolated economic activities. Overall, this description corresponds well to the observations we made in the field. However, the method has as well some disadvantages: (1) it is not certain the results can make sense from a statistical point of view; (2) the thresholds are defined in a way to show relevant differences, based on an expert opinion, and can be biased; (3) it might be that the results cannot be reproduced with machine learning or other forms of artificial intelligence, making it difficult to obtain an extrapolated map for the whole territory of Flanders.

Methods		Distance clustering	Activities clustering	Results +	Results -	How to improve?
		First clustering	Second, new clustering			
1	DBSCAN + Factor analysis	DBSCAN: parcels with economic use clustered as points (20m, 50, 100, 500, 5000 m)	Factor analysis: 2 groups	Distance clustering: unbiased look in clustering method	Distance clustering: Because of the random function in DBSCAN, some points are overlooked (**Fehler! Verweisquelle konnte nicht gefunden werden.**) Activities clustering: Only 2 factor gives not much differentiation.	Trying another algoritm for distance clustering
2a	Cluster-Within + Factor analysis and PCA	Cluster Within: Parcels with economic use grouped as polygons (0,1m, 20m, 90m, 500m)	Factor analysis: 16 groups	Distance clustering: ClusterWithin groups economic parcels in more are less meaningful groups, based on distance.	Distance clustering: Some groups should be together. Width of (broad) roads slices clusters into smaller groups (**Fehler! Verweisquelle konnte nicht gefunden werden.**) Activities clustering: -Not all categories seem to be spatially relevant	Trying another distance clustering in order to capture different groups in one group, so that both sides on the same street are in one group
2b			PCA: 9 groups	Activities clustering: PCA method is more robust, used in Numerical Ecology (Legendre & Legendre, 2013)	Activities clustering: -Not all categories seem to be spatially relevant -Clusters are either too big or too small. The size of the parcels matters (**Fehler! Verweisquelle konnte nicht gefunden werden.**)	
3	DBSCAN	DBSCAN: parcels with economic use clustered as main access points /front entrances (distances ranges from 25 to 250m)	N/A	Distance clustering: Overbridging the distance of small roads, so that the two sides of the roads are in one group is sucessful	Distance clustering: Because of the random function in DBScan, distance points are overlooked (**Fehler! Verweisquelle konnte nicht gefunden werden.**) -Defining main entrances difficult at corner parcels and asymetrical polygons -Clusters are either too big or too small. The size of the parcels matter (**Fehler! Verweisquelle konnte nicht gefunden werden.**)	Trying another algoritm for distance clustering
4	Predefined building blocks	Based on predefined distance between building blocks (includes all parcels of the settlement area, not just economic use parcels) and the roads. (25m, 50m, 70m)	Activities added to building blocks. Used of predefined tresholds to categorise the blocks into 23 categories	Distance clustering: -Differentiation is successful, regardless if the parcels are big or small (**Fehler! Verweisquelle konnte nicht gefunden werden.**) -Type of road is a defining factor for economic activities (e.g. one end of building block is at a main road; other end at a back road) Activities clustering: -Monitoring changes in building blocks is easier, as they stay always the same -All parcels in settlement area are included, which makes it easier to add more characteristics that are non-economic	-It is not sure the results make statistically sense -hierarchical system, we might be biased (e.g. defining tresholds)	Do some statistical analysis

Table 1: Summary of the used methods to make distance clusters and then regroup them into activities clusters

5 FIRST RESULTS OF USING THE SEVERAL METHODS WITH ADMINISTRATIVE DATABASES

As mentioned before, the administrative database (VKBO) that contains information about the location and the type of economic activities shows discrepansies with the data collected on the field (Gruijthuijsen et al., 2018). Next to this, each record in the VKBO contains a lot of NACE-codes. Choosing one activity, is not an easy task. Comparing the administrative database with the field observations, there are a lot more records in the VKBO. On average, the number of economic locations visible on the field accounts for only 48% of the number of businesses registered in the VKBO data. In certain residential area's there could be three times as much activities in de administrative database. There is definitely some extra research to do in order to determine for which categories of economic activity the discrepancy is large and for which the information from VKBO does give a good picture of the actual activity.

Nonetheless, some first tests with the VKBO, using the previous distance and activities methods, have been done, trying to replicate: (1) the PCA results via machine learning (ML) algoritms and (2) the predifined building blocks. The test with ML consisted of two steps. First of all, the results of the PCA within the mapped area of the inventory of the parcels with economic use are scored on accuracy according to ML algortims K-Neighbours Classifier and Random Forest Classifier. This resulted into high accuracies varying between 0,93 and 0,95. The next step is to label the geografically obtained distance clusters with the activities (NACE-codes) on the parcels as available in the VKBO. Afterwards, a model is again trained through ML algorithms to find, this time on the basis of the NACE activities, the obtained activities clusters. This approach gave results around 0,59 and 0,57 accuracy.

The last test consisted of using all available NACE-codes and linking them to the predefined buildings blocks of the distance clustering. New thresholds had to be developped, as the non-visible businesses are also included in the data. Considering the dominance of service activities, most of the parameters were set rather low. Figure 6 illustrates the first results for the Flemish city of Hasselt.

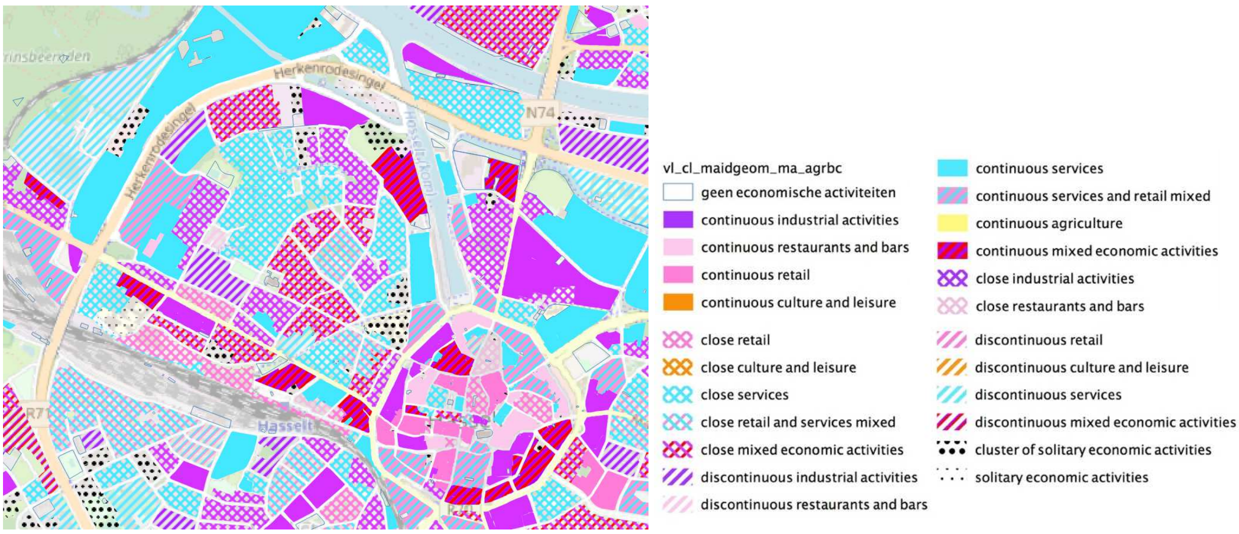

Figure 6: Activities clustering within the predifined building blocks, based on all available NACE-codes, in the Flemish city of Hasselt. (Background layer: Open Street Map)

6 CONCLUSION

Our recent work focussed on comparing potential methods for creating a map of economic ecotopes for Flanders, based on the experience from mapping economic a small part of our territory. We produced different methods to get to an automated or scripted result, based on an inventory of economic activities. This shows that (1) clusters of economic activities exists and (2) that types are statistically different, as the PCA and FA show. However, spatially interpreting these clusters proved to be more difficult. So far, adding some spatial information to the characteristics seems to be necessary. Therefore,we also created (3) a hierarchical, conditional method (based on the building blocks) to obtain similar results to drawing the types manually, and (4) proved that this can also be done using the registry of companies database. It is not yet known if this clustering method with the building blocks makes sense from a statistical point of view or if it can be reproduced for the entire area of Flanders. In conclusion,, for each of these methods, many difficulties need to be solved from the point of view of spatial interpretation, statistics and choice of treshholds,and more exploring of different ways of doing this will be needed. We consider it a big advantage to be able to compare this variety of approaches as we assume it will help us make an educated and informed choice on how to represent the map of types of economic ecotopes in Flanders, and to use it to provide policy advice.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

The next steps will include the development of both a statistical and an hierarchical method to produce this map. We will also try to understand what makes the key differences between the field inventory of visible economic activities and the location of companies in the registry (VKBO). Regarding the DBSCAN and ST_ClusterWithin, we think that a more in depht knowledge of how the algorithm (and its derivatives e.g. HDBSCAN, GDBSCAN) works with our type of data will be needed.

1 ABSTRACT

Die Erreichung der Klimaziele und eine menschengerechte Gestaltung unserer Städte sind in hohem Maße von einer Reorganisation des Verkehrssektors auf allen Ebenen abhängig. Die Initiierung eines Paradigmenwechsels muss dabei als Strukturveränderung verstanden werden. In einem interdisziplinären Ansatz beleuchten wir das Thema aus Sicht der Ingenieur- und Planungswissenschaften, Soziologie sowie Politikwissenschaft. Anhand der Multi-Level-Perspektive beschreiben wir Rollen, Abhängigkeiten und den Einfluss von Akteurinnen und Akteuren sowie strukturelle Barrieren der Mobilitätswende und weisen auf mögliche Lösungen hin. Die Ergebnisse zeigen, dass dringend auch eine „Mobilitätswende in den Köpfen" der Verantwortlichen in Politik, Planung, Verwaltung und Wissenschaft erforderlich ist, da sie Rahmenbedingungen vorgeben oder beeinflussen, Entscheidungsgrundlagen schaffen und/oder unterstützen und Maßnahmen definieren und umsetzen (sollen).

Keywords: Governance, Transoformation, Verkehr, Mobilität, Multi-Level-Perspektive

2 EINLEITUNG

Speziell in Bezug auf die voranschreitende Klimakrise ist Veränderung im Verkehrssektor überfällig. Die globalen CO2-Emissionen im Verkehrssektor sind zwischen 1970 und 2010 um 250% gestiegen, wobei der Straßenverkehr dabei den Großteil ausmacht (Sims et al., 2014). In vielen europäischen Staaten steigen die Verkehrsemissionen weiterhin an. Österreich verzeichnet seit 2014 wieder einen kontinuierlichen Anstieg. Zwischen 1990 und 2017 erhöhten sich die nationalen Verkehrsemissionen um 71,8% und machten damit Einsparungen in anderen Sektoren wieder zunichte (Umweltbundesamt, 2019).

Immer mehr Berechnungen und Simulationen zur Ressourcennutzung kommen unter Berücksichtigung der planetaren Grenzen (Klimawandel, Biodiversität, verfügbare Ressourcen) zu dem Ergebnis, dass Nachhaltigkeitsziele nur dann erreicht werden können, wenn es im Verkehrssektor zu einer radikalen Wende kommt, die über eine reine Antriebswende - wie etwa der Umstieg auf Elektromotoren – und die Einführung neuer Technologien hinausgeht. Jüngste Publikationen zeigen dies für globale Analysen (de Blas et al., 2020, Millward-Hopkins et al., 2020). Auf österreichischer Ebene wurde dies im „Sachstandsbericht Mobilität" des Umweltbundesamts (Heinfellner et al., 2018) quantifiziert. Zusätzlich zur Umstellung auf nicht-fossile Antriebe ist eine drastische Senkung der Fahrleistung im motorisierten Individualverkehr (MIV) notwendig.

Wir benötigen also eine Mobilitätswende, die nicht nur eine Verhaltensänderung bei der Verkehrsmittelwahl („Verkehrswende") bedeutet, sondern Mobilität ganzheitlich betrachtet, unter Berücksichtigung weiterer Aspekte wie beispielsweise der Raumplanung und sozioökonomischer Rahmenbedingungen und Wirkungen.

Das Mobilitätsverhalten hängt von einer Vielzahl an Einflussfaktoren ab, wie der Siedlungs- und Verkehrsinfrastruktur als Voraussetzung für Verhaltensalternativen, dem Wegetyp sowie Geld-, Zeit- und Bequemlichkeitskosten, als auch persönlichen Einstellungs- und Wertemustern (vgl. Haselsteiner et al. 2020; Neugebauer, 2004; Seebauer 2011). Diese verschiedenen Faktoren führen dazu, dass sich bestimmte Gewohnheiten im Mobilitätsverhalten herausbilden. Für einen umfassenden Verhaltenswandel ist es nun Ziel und Schwierigkeit zugleich, diese Gewohnheiten aufzubrechen und so Raum für Verhaltensalternativen zu schaffen. Da die Verfügbarkeit und Attraktivität der unterschiedlichen Verkehrsmittel Grundlage für das Verhalten sind, müssen die Strukturen (baulich, rechtlich, finanziell, organisatorisch), die diese bedingen, verändert werden. Es ist also ein umfassender systemischer Wandel notwendig, eine Transformation des bestehenden sozio-technischen Verkehrssystems.

Es gibt eine große Kluft zwischen dem, was notwendig wäre, um Klima- und Nachhaltigkeitsziele zu erreichen und dem, was in der Praxis umgesetzt, beziehungsweise dem, was in der Politik diskutiert wird.

Manche sprechen gar von Tabus, sogenannten „transport taboos“ (Gössling and Cohen, 2014): für den Großteil der Akteurinnen und Akteure undenkbare Maßnahmen, die vom etablierten Regime daher entweder nicht adressiert oder als zu „radikal“ oder politisch nicht umsetzbar disqualifiziert werden. Beispiele hierfür finden sich zur Genüge, etwa das Herabsetzen von Tempolimits, den Rückbau von Straßeninfrastruktur oder die Einführung einer CO2-Steuer in solch einer Höhe, die einen tatsächlichen Lenkungseffekt herbeiführen würde.

Verkehrspolitische Entscheidungen basieren nach wie vor vielfach auf nicht kritisch hinterfragten Theorien und Kernprinzipien. Sie sind Grundlage zur Verteidigungshaltung des Status-quo und Aufrechterhaltung einer zum Teil auch in Normen und Gesetzen festgelegten Wertehierarchie. Dogmen wie „Erreichbarkeit“, „maßgebliche Geschwindigkeit“ oder die – meist monomodal diskutierte ¬ „Beseitigung von Kapazitätsengpässen“ werden im Rahmen der Stabilisierungsstrategie um „jeden Preis verteidigt“. Es wird technische Objektivität vorgegeben, wobei die zu Grunde liegenden Annahmen nicht explizit ausgesprochen werden und oft nicht öffentlich sind. Veränderte Annahmen, die den Status Quo in Frage stellen, werden nicht anerkannt.

3 SYSTEMTHEORIE, REGIMES UND NACHHALTIGKEITS-TRANSFORMATION

3.1 Menschliche Bedürfnisse und „Provisioning“-Systeme

Das von Mattioli (2016) vorgestelltee und durch Brand-Correa, et al. (2020) weiterentwickelte Modell zur Verknüpfung von menschlichen Bedürfnissen und „provisioning“ (Bereitstellungs-)Systemen zeigt Angriffspunkte zur Intervention im Verkehrssystem auf. Die Basis bilden dabei Stufen der Bedürfnisbefriedigung, die mit dem privaten Pkw als Beispiel veranschaulicht werden. Menschen haben Grundbedürfnisse, die sie mithilfe von „Befriedigern“ („need satisfiers“) erfüllen. Während die Nutzung eines Pkws selbst kein Bedürfnis ist, fungiert der Pkw als Befriediger von Bedürfnissen höherer Stufen. Ein Beispiel ist das Bedürfnis des Lebensunterhalts. Menschen müssen Geld verdienen, um ihren Lebensunterhalt zu bestreiten. Dafür müssen sie von ihrem Zuhause zu ihrem Arbeitsort gelangen. Befriediger erster Stufe sind sozio-technische „provisioning“ Systeme wie Infrastruktur (z.B. eine Straße, die den Wohnort mit dem Arbeitsplatz verbindet). Auf der zweiten Stufe sind Aktivitäten, auf der dritten Dienstleistungen und auf der vierten spezifische Produkte, wie etwa der Pkw.

Interventionen auf der ersten Stude sind zwar die effektivsten, jedoch gleichzeitig jene, wo Veränderung am schwierigsten durchzusetzen ist. Das kann mit einer Zahnrad-Metapher visualisiert werden (vgl. Brand-Correa, et al., 2020), oder als Hebelpunkte (siehe Abb. 1). Eine Intervention auf der ersten Stufe, um eine Abkehr vom Pkw-orientierten System zu schaffen, müsste einen Wandel in der Bereitstellung von nicht-Pkw-Infrastruktur, verbesserter und integrierter ÖV-Systeme und Veränderungen in Stadtplanung, inklusive der Verlagerung von Arbeitsplätzen an besser erreichbarere Gebiete beinhalten (Brand-Correa, et al., 2020) – also eine Veränderung der Systemstrukturen. Eine Maßnahme auf vierter Stufe wäre hingegen zum Beispiel der Umstieg auf Pkws, die mit Biokraftstoff angetrieben werden (Veränderung eines einzelnen Parameters). Dies stellt zwar eine wesentlich einfachere Aufgabe dar, die jedoch nicht annährend effektive Klimawirkungen erzielen kann. Sozio-technische „provisioning“ Systeme bestehen aber nicht nur aus der gebauten Infrastruktur, sondern auch aus Institutionen, ökonoischen und politischen Logiken – letzten Ende also Denkweisen und Paradigmen. Diese zu adressieren mag wie eine unmögliche Herausforderung erscheinen und Akteurinnen und Akteure im Verkehrssektor könnten dies als Rechtfertigung sehen nicht zu handeln. Im Umfang dieser Studie ist es zwar nicht möglich, die fundamentalen wirtschaftlichen und politischen Logiken, welche auch die Basis für die Rahmenbedingungen im Verkehr bilden, im Detail zu analysieren, es ist dennoch notwendig, auch den Verkehrssektor zu adressieren. In diesem Artikel fokussieren wir dabei auf gebaute Infrastrukturen sowie rechtliche und administrative Prozesse zur Infrastrukturplanung.

3.2 Multi-Level-Perspektive als Transformationstheorie

Ein relativ junges wissenschaftliches Feld beschäftigt sich mit der Nachhaltigkeitstransition, also der Frage, wie bestehende sozio-technische Systeme, die nicht nachhaltig sind, zu nachhaltigen Systemen verändert werden können. Markard et al. (2012) beschreiben die Entstehung dieses neuen Forschungsfeldes und seine Notwendigkeit. In einigen Sektoren, wie der Energieversorgung, Landwirtschaft und eben auch dem Verkehrssektor zeichnen sich zunehmend ökologische, soziale und ökonomische Probleme ab. Im Verkehrssektor zeigen sich die Probleme beispielsweise in lokaler Luftverschmutzung, der Erschöpfung fossiler Brennstoffe, CO2-Emissionen und Unfallrisiken. Aufgrund von Entwicklungen in der Vergangenheit (so genannter Pfadabhängigkeiten) und „Lock-In"-Effekten verändern sich die etablierten Systeme nur inkrementell und nicht radikal. Diese inkrementellen Veränderungen werden jedoch nicht ausreichen, um den drohenden Herausforderungen der Nachhaltigkeit rechtzeitig gerecht zu werden. Daher beschäftigt sich die Forschung der Nachhaltigkeitstransition mit der Frage, wie die notwendige radikale Veränderung dieser etablierten Systeme gefördert werden kann.

Die Multi- Level Perspektive (MLP) nach Geels and Schot (2007) hat sich dabei als anschaulichste Theorie zur Beschreibung der notwendigen Veränderungen und bestehender Barrieren im Verkehrssystem herauskristallisiert. Die MLP unterscheidet drei Ebenen: (exogene) Rahmenbedingungen, Regime und Nischen (siehe Abb. 2). Das zentrale Regime beinhaltet die dynamisch stabilen, etablierten und hegemonialen Praktiken, Diskurse, Institutionen und Artefakte (Vogel, 2015). Rip and Kemp (1998) definieren ein Regime als „den zusammenhängenden Komplex aus Wissen, Technik, Produktionsprozessen, Produktcharakteristiken, Fähigkeiten und Prozessen, Nutzerbedürfnissen, gesetzlichen Anforderungen, Institutionen und Infrastruktur". Innerhalb des Regimes können drei Dimensionen unterschieden werden: (1) materielle Technologien wie Artefakte, Infrastruktur und Geräte; (2) Akteurinnen, Akteure und soziale Gruppen, die Technologien entwickeln, nutzen und regulieren; und (3) Regeln (formale und informelle), welche die Wahrnehmung und Handlungen der Akteurinnen, Akteure und Gruppen leiten (Geels, 2007). Eine Transition im Sinne der MLP ist definiert als der Übergang von einem Regime zu einem anderen Regime. Nischen und Rahmenbedingungen werden in Relation zu dem Regime definiert.

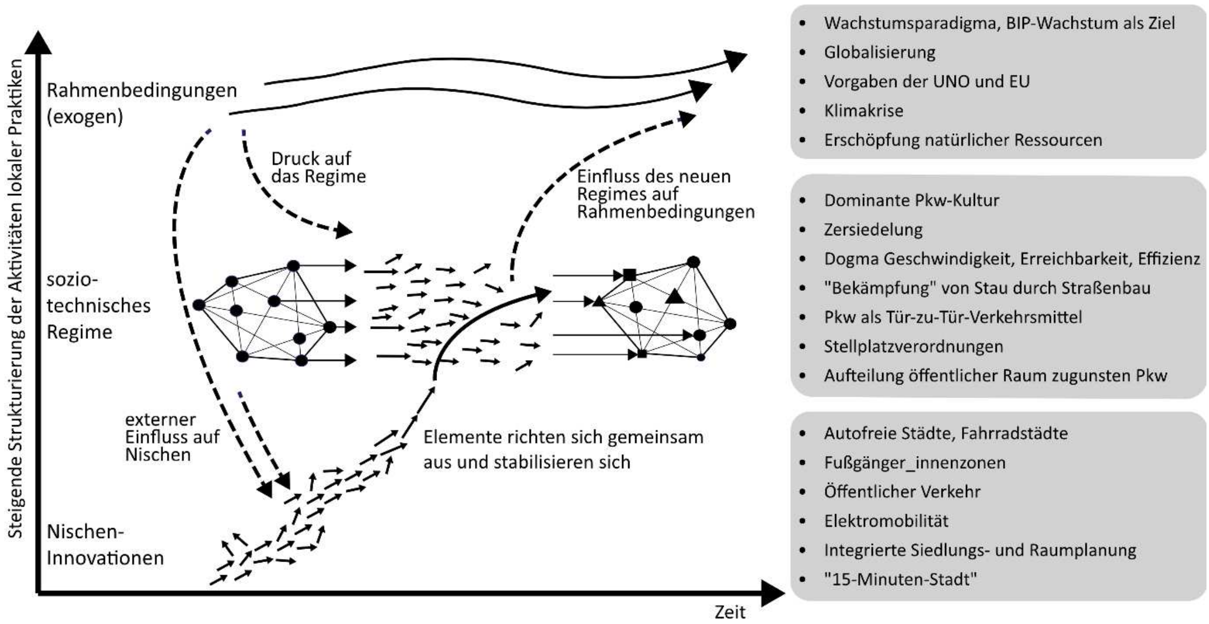

Abb. 2: Multi-Level-Perspektive, adaptierte Illustration von Haselsteiner et al. (2020), basierend auf Geels and Schot (2007)

Die übergeordneten Rahmenbedingungen stellen exogene Faktoren dar, die auf das Regime wirken, in der Betrachtung aber nicht direkt Teil des Regimes sind. Die Abgrenzung zwischen Regime und den übergeordneten Rahmenbedingungen wird in der Literatur zwar intensiv diskutiert, aber nicht klar definiert (Vogel, 2015). Daher ist die Abgrenzung stark vom analysierten System und der Sicht der analysierenden Person abhängig. Gemäß dieser Theorie können die Rahmenbedingungen Druck auf das Regime ausüben. Durch den Druck verändern sich die Verbindungen im Regime, die etablierte Ordnung wird aufgebrochen. Dieser destabilisierte Zustand des Regimes kennzeichnet ein „window of opportunity“, stellt also ein „Möglichkeitsfenster“ dar, während dem es möglich ist, eine neue Konfiguration des Regimes herzustellen und Nischenentwicklungen darin aufzunehmen. Nischen sind definiert als Technologien oder Praktiken, die substanziell vom existierenden Regime abweichen. Sie können das Regime unterstützen oder als Gegnerin gesehen werden. Auf dieser Ebene agieren unterschiedliche Akteurinnen und Akteure in unkoordinierter Weise. Durch gemeinsame Ausrichtung können sich die Entwicklungen zu einer dominanten Form stabilisieren, die bei einem Möglichkeitsfenster den „Sprung“ in das Regime schaffen. So hat sich beispielsweise auch der private Pkw in der Vergangenheit vom Nischen- zum Massenprodukt entwickelt.

3.3 Das „Car-Regime“

Bezogen auf den Verkehrssektor in Österreich heutzutage – wie in allen Ländern des globalen Nordens – lässt sich das etablierte System als „Car-Regime“, also Pkw-Regime beschreiben (Zijlstra and Avelino, 2012, Marletto, 2011). Durch das vorherrschende System wird der private Pkw als Verkehrsmittel vielfach bevorzugt und Strukturen an ihm ausgerichtet. Das hemmt die Implementierung von klimawirksamen Maßnahmen und sorgt dafür, dass auch heute noch Infrastrukturen geplant und finanziert werden, welche nachweislich zu einer drastischen und kontinuierlichen Steigerung der CO2-Emissionen sowohl direkt als auch indirekt durch ihre verursachten Folgewirkungen und Rebound-Effekte führen.

Mattioli et al. (2020) beschreiben die derzeitige Pkw-Abhängigkeit (im System) in detaillierter Form anhand von sechs Teilsystemen: der Bereitstellung von Infrastruktur, der Pkw-Industrie, Flächennutzungs-Mustern, der Vernachlässigung des öffentlichen Verkehrs und der Pkw-Kultur. Diese Teilsysteme sind miteinander verbunden und wirken zusammen als positiver Regelkreis, der sich selbst verstärkt. Hier sei als Beispiel nur die Bereitstellung von Infrastruktur herausgegriffen: die öffentliche Hand plant und finanziert Infrastrukturen wie Straßen, Parkplätze und Institutionen, welche die Pkw-Nutzung unterstützen. Straßen und Parkplätze können entweder durch die Vereinnahmung bestehender Infrastrukturen, wie etwa bei innerstädtischen Flächen oder durch die Bereitstellung neuer Infrastruktur, wie beispielsweise durch zusätzliche Straßen geschehen. Im ersten Fall werden Flächen genutzt, die zuvor als öffentlicher Raum primär allen Menschen zur Verfügung standen. Durch entsprechende Gesetze wie der Straßenverkehrsordnung und Stellplatzverpflichtungen wird der neue Vorrang für Pkw auch formal geregelt. Dadurch werden gleichzeitig der ÖV benachteiligt und die Bedingungen für aktive Mobilität verschlechtert. Die Bereitstellung von Infrastruktur bildet die Basis für Flächennutzungs-Muster die auf Pkw-Nutzung angewiesen sind, wie etwa zersiedelte Strukturen. Diese Entwicklungen sind im Sinne der Industrie, da dies mit einem erhöhten Bedarf an Pkw einhergeht. Die Fahrzeughersteller und Zulieferbetriebe sind zu einem der Haupt-Industriesektoren herangewachsen. Sie produzieren in sehr großen Skalen und haben eine hohe wirtschaftliche Bedeutung, wodurch Regierungen von den Arbeitsplätzen und Staatseinnahmen durch die Unternehmen in gewisser Weise abhängig sind. Außerdem entstehen durch Pkw-orientierte Strukturen Praktiken und Gewohnheiten, die zur Verfestigung einer „Pkw-Kultur“ beitragen und somit wiederum zu Entscheidungen für weitere Pkw-Infrastrukturen führen. Aus diesem Teufelskreis gilt es auszubrechen.

3.4 Die Rolle der Akteurinnen und Akteure

Akteurinnen und Akteurein diesem „Car-regime“ umfassen Politikerinnen und Politiker, die planende und administrative Verwaltung (Stadt, Land, Bund), Vertreterinnen und Vertreter der Behörden, externe Planerinnen und Planer, Bürgerinnen und Bürger, Interessenvertretungen und Medien (vgl. (Kloss, 2009). Sie alle sind in Strukturen eingebettet, die ihnen unterschiedliche Freiheitsgrade und Handlungsspielräume ermöglichen. Innerhalb des Regimes verbinden institutionelle Strukturen die technischen Artefakte, Regeln und Akteurinnen und Akteure miteinander. Diese können ihre Handlungen nur so weit bestimmen, wie es die Freiheitsgrade durch die vorgegebenen Strukturen erlauben. Basierend auf Gidden’s Strukturationstheorie (Giddens, 1984) haben ihre Handlungen jedoch auch Einfluss auf die anderen Regime-Elemente und verändern diese, so entsteht eine Wechselwirkung mit spiralförmigem Verlauf über die Zeit.

In den letzten Jahrzehnten hat sich die Rolle des Staates in seinen Beziehungen zu Wirtschaft, Wissenschaft und Zivilgesellschaft zusehends verändert. Die wirtschaftliche Entgrenzung der 1980er Jahre führte zudem zur Globalisierung und zum internationalen ökonomischen Wettbewerb und zu einer stärkeren Einbeziehung der Wirtschaft in politische Prozesse. Die immer stärkere Einbeziehung wissenschaftlicher Expertinnen und Experten in Entscheidungsfindungsprozesse wurde durch die angeführten Entwicklungen, besonders aber die Globalisierung politischer Probleme, beschleunigt. Diese Veränderungen in der Art und Weise der Beziehungen zwischen Staat, Wirtschaft, Wissenschaft und Zivilgesellschaft werden auch häufig mit dem Schlagwort „von Government zu Governance“ charakterisiert.

Die spezifischen Anforderungsprozesse im Verkehrsbereich drücken sich durch die hohe Diversität an Interessensgruppen aus, was einen hohen Aufwand an Planung und Kompromissbereitschaft voraussetzt. In diese politischen Prozesse werden immer mehr institutionalisierte Gruppen involviert, die eine faktenbasierte Entscheidungsgrundlage schaffen sollen, wie zum Beispiel Wissenschaftlerinnen, Wissenschaftler, Expertinnen und Experten. Diese Einbindung führt jedoch nicht immer zu den gewünschten Ergebnissen, da die von Expertinnen und Expertenvorgeschlagenen Maßnahmen häufig keine Umsetzung finden und der Prozess also teilweise einen symbolischen Charakter annimmt, um die politischen Prozesse zu legitimieren (vgl. Bandelow and Kundolf (2011).

In der Verkehrsplanung zeigen sich die unterschiedlichen Interessenslagen der Akteurinnen und Akteure auch durch unterschiedliche Auswirkungen von Verkehrsinfrastrukturen, die sich auf lokaler, regionaler und überregionaler Ebene ergeben. Oft stehen überregionale wirtschaftliche Überlegungen den lokalen Auswirkungen entgegen. Dabei werden von den handelnden Akteurinnen und Akteuren kurzfristige ökonomische Aspekte für wichtiger erachtet als eine ökologische Nachhaltigkeit und Ressourcenschonung. Lange Zeitverzögerungen zwischen Handlungen und Wirkungen reduzieren die Bereitschaft zur Aktivierung wirklicher Transformationsprozesse (vgl. Brezina und Fernandez, 2017).. Strukturelle Rahmenbedingungen eines auf langsame Veränderungen ausgerichteten politischen Systems erschweren weitreichende Reformen.

Individuelle und vorurteilsspezifische Interpretationen, Wertehaltungen, Ausbildung, rechtliche Grundlagen (Regelwerke) und Indikatoren bestimmen die wahrgenommene Realität und was als Problem definiert wird. Ein beharrliches Verfolgen der „falschen“ Ziele (hohe Geschwindigkeit, permanente Kapazitätserweiterungen, etc.) führt zu zunehmender Abhängigkeit dieses “Regelhandelns” (“Lock-In”). Die erforderlichen Maßnahmen zur Dekarbonisierung des Verkehrssystems sind bekannt. Einzelne Maßnahmen reichen nicht aus um eine Trendwende zu verwirklichen, es braucht vielmehr abgestimmte Maßnahmenbündel, die unterschiedliche Faktoren adressieren, wie Preissignale, Angebotsverbesserungen und eine zusätzliche Veränderung des Bewusstseins (vgl. Haselsteiner et al., 2020). Dabei wird deutlich, dass derzeit nicht nur enorme Defizite in der Bereitschaft, dem politischen Willen und der Organisationsmacht zur

Umsetzung existieren, sondern, dass auch eine realistische Einschätzung über die notwendige Maßnahmenintensität fehlt, um nur annähernd die Klimaziele im Verkehrssektor zu erreichen. Bereits quantifizierte Maßnahmen (wie etwa im Sachstandsbericht Mobilität) sollten rasch umgesetzt werden. Darüber hinaus sind jedoch weitere, auf Prozessstrukturen fokussierte Maßnahmen zu forcieren um eine tatsächliche Transformation zu initiieren (vgl. Haselsteiner et al., 2020).

3.5 „Best“ Practice bisher nur in Nischen

Es gibt einzelne gute Ansätze, Prozesse in der Verkehrsplanung und -politik so zu gestalten, dass Maßnahmen unterstützt werden, welche zur Mobilitätswende beitragen („Best“-Practice Beispiele). Diese Ansätze sind aber nach wie vor als Nischenentwicklungen zu kategorisieren, wenn sie, z. B. eingebettet in weiterhin nicht nachhaltige Entwicklungen einer Metropolregion, in der Stadt alleine nicht die erforderlichen Wirkungen zur tatsächlichen Einleitung einer Mobilitätswende entfalten können.

Dieses Nischendasein wird am Beispiel Kopenhagens ersichtlich. Die dänische Hauptstadt gilt als Vorreiterin der Radverkehrsplanung, nach der sogar ein Index zur Beurteilung der Fahrradfreundlichkeit einer Stadt benannt ist („Copenhagenize Index“). Der sogenannte „Fingerplan“ ist die eigentliche Basis der integrierten Stadtentwicklungs- und Verkehrsplanung der Metropolregion, demzufolge Siedlungen entlang von fingerartigen ÖV-Achsen angelegt werden sollen. Trotzdem verzeichnete das Umland mit 82% den höchsten MIV-Anteil einer europäischen Metropolregion (Driscoll, 2014). Driscoll (2014) zeigt in seiner Analyse, dass diese am ÖV orientierte Planung durch ringförmige Straßenbauprojekte unterminiert wird. Pfadabhängigkeiten, wie die Konstruktion des Fehmarnbelts und steigende Diskrepanzen zwischen Wohnortpräferenzen und Beschäftigungsmöglichkeiten, haben zu einem „Carbon Lock-In“ geführt. Dadurch werden trotz Protesten der lokalen Bevölkerung Straßenbauprojekte immer noch weiterverfolgt und der Autoverkehr dominiert weiterhin das Verkehrssystem.

4 LÖSUNGSANSÄTZE UND INTERVENTIONSSTRATEGIEN

Um Nischen in das Regime zu hieven, müssen unterschiedliche Ebenen der MLP adressiert werden. Individuen sind beispielsweise Teil des Systems auf allen Ebenen. Sie können mit ihrer Weltsicht und ihren Einstellungen auch die Visionen und Paradigmen der Rahmenbedingungen auf dem Makro-Level beeinflussen (Göpel, 2016). Eine Interventionsstrategie kann daher die Aufklärung über das Thema sein, um so auf individueller Ebene neue Sichtweisen aufzuzeigen, die das gemeinsame Paradigma verändern können.

Ein derartiges Vorgehen könnte unter anderem durch bildungspolitische Weichenstellungen unterstützt werden, innerhalb derer sich tertiäre Bildungsinstitutionen und Forschungseinrichtungen stärker in den Dienst der Lösung gesellschaftlicher Problemstellungen stellen. Damit würden Bildung und Wissenschaft politischen Entwicklungen Folge leisten, als Teil derer in den letzten Jahrzehnten aus den Politikfeldern Forschungs- und Technologiepolitik sowie aus sektoralen Politikfeldern wie beispielsweise Teilen der Verkehrspolitik zusehends eine integrale Innovationspolitik wird (Biegelbauer 2013). Jüngste Beispiele sind die Missionen im Rahmen des EU Rahmenprogramms Horizon Europe, die sich der Lösung gesellschaftlicher Problemstellungen vor dem expliziten Hintergrund von Nachhaltigkeitszielen verschrieben haben und jeweils von den sektorspezifischen Generaldirektionen geleitet werden.

Eine weitere Interventionsstrategie im Sinne der Nachhaltigkeitstransition ist die Stärkung von Nischen durch Allianzen. Schließen sich Akteurinnen und Akteure zusammen, können Emergenzen ermöglicht werden und so gemeinsam mehr bewirkt werden als durch individuelle Bestrebungen. Diese Allianzen können auch innerhalb der bestehenden Institutionen gefördert werden. Die Bildung einer derartigen Allianz könnte beispielsweise durch die international gut erprobte Möglichkeit unterstützt werden, Akteurinnen und Akteure mit sehr unterschiedlichen Hintergründen, Zielsetzungen, Interessenslagen und weltanschaulichen Positionen zu einem Annäherungsprozess zu bewegen: durch einen partizipativen Foresight (Dinges et al, 2018). In einem derartigen Prozess werden in der Gruppe in einer ersten Phase Visionen und grundlegende Vorstellungen von einer mittel- oder langfristigen Zukunft ermittelt. Dabei werden bewusst Methoden eingesetzt, die es erleichtern aus dem Alltag herauszutreten, unterschiedliche Positionen zuzulassen und auch selbst die eingespielten Muster hinter sich zu lassen. Unterschiedliche Faktoren, welche die Zukunft beeinflussen können, werden herausgearbeitet und in der Gruppe beurteilt. In einem weiteren Schritt werden aus diesen Visionen von einer Zukunft (beispielsweise für das Jahr 2050) Ziele abgeleitet, die wiederum gemeinschaftlich diskutiert werden. Nach der Verfestigung dieser Ziele werden im Rahmen eines Back-Casting Prozesses Ziele bis zur nahen Zukunft abgeleitet (Wilhelmer und Nagel, 2013).

Die Wirkung der angeführten Maßnahmen ließe sich auch in einen größeren Zusammenhang einbetten, wenn etwa die Nachhaltigkeit als Ziel der Politik eindeutiger als bisher festgeschrieben und im Sinne eines übergeordneten Staatszieles in der Verfassung verankert werden würde. Eine derartige Maßnahme hat einerseits - auch durch die im Zuge der Inkraftsetzung entstehende gesellschaftliche Debatte - einen symbolischen Charakter, indem sie auf die Wichtigkeit einer nachhaltigen Entwicklung verweist. Andererseits sind Staatsziele aber durchaus rechtlich verbindlich, wie etwa im Verfassungsgesetz zur immerwährenden Neutralität Österreichs, dem Verbot nationalsozialistischer Wiederbetätigung oder der Gleichstellung zwischen Mann und Frau als Teil der Rechtsordnung jeweils festgehalten. Dadurch sind derartige Zielsetzungen beim Beschluss neuer Gesetze sowie deren Auslegung im Bereich von Verwaltung und Rechtsprechung verbindlich einzuhalten und können auch eingeklagt werden.

5 SCHLUSSFOLGERUNGEN

Die Initiierung von politischen Maßnahmen für eine ökologische Transformation im Verkehrssystem wäre die Aufgabe von Staat und Politik. Deren Abhängigkeit von globalisierten Konzernen und Märkten einerseits und einer demokratischen Legitimation andererseits, führen zur zulässigen Frage, ob der Staat überhaupt ernsthaft den Willen hat, das Verkehrssystem zeitkritisch zu verändern und einen radikalen Strukturwandel zu etablieren. Vergleicht man die bisherigen Entwicklungen wie z. B. jener der CO2-Emissionen im Verkehrssektor, dem Flächenverbrauch durch Verkehrsinfrastrukturen oder der stetigen Zunahme des Verkehrsaufwandes, kann diese Frage eindeutig verneint werden. Es braucht eine Neuausrichtung aller Prozesse und Strukturen sowie Transparenz der Entscheidungsprozesse (Personen, Strukturen, Prozesse, Gremien, etc.). Ebenso eine neue Wertehierarchie in den Richtlinien, Vorschriften und Gesetzen und daher eine Änderung des Mindsets der Entscheiderinnen und Entscheider (Mobilitätswende „in den Köpfen“). Die Abschätzung von Wirkungen (ökologisch, sozial) infolge von regulatorischen Maßnahmen und Infrastrukturbauten sollten als Basis der Entscheidungen fungieren.

Die Analyse der Transformationsprozesse für eine Mobilitätswende zeigt jedenfalls das Erfordernis der transdisziplinären Betrachtung. Für die Einleitung eines Paradigmenwechsels reichen das Wissen und die Werkzeuge der Verkehrsplanung und –technik nicht aus. Nur im Zuge von transdisziplinärer Forschung, Zusammenarbeit und transsektoraler Planung lässt sich herausfinden, wie es möglich sein wird, die bekannten Maßnahmen im Verkehrssektor in einer Form umzusetzen, die sozial und politisch akzeptiert wird und einen tatsächlichen Transformationsprozess einleitet.

1 ABSTRACT

Metropolitan regions worldwide face the same problems: air pollution, congestion, urban sprawl. Decades of interventions by policy makers and planners did not change this fact. The methods of System Dynamics reveal that one of the main causes is a lack of understanding of the complex interactions between urban, peri-urban and peripheral regions. Therefore, it is essential to improve systems thinking skills of policy makers, planners and the public. Educational games promote the development of cognitive, spatial and motor skills and can be used to teach facts (e.g. knowledge, retrieval, memorization, retention of knowledge), principles (e.g. cause-and-effect relationships) and complex problem solving. Hence, educational games and simulations are powerful tools to improve systems thinking skills – even for very young age groups.

The objective of the nationally funded project Systemcheck (2019-2020) was to make use of the abovementioned capabilities. An interactive, digital teaching and learning game based on simulations of social and ecological effects of mobility and transport in metropolitan and peripheral regions was developed and tested in classrooms. The game specifically addresses topics of the Austrian 6th grade syllabus for the subject geography and economics. The game, on the one hand, enables students to learn and practise geography subject matters and on the other hand to develop systemic thinking skills. The basic framework of the multi-level game is the vita of a person from primary school through to adulthood. Players have to solve different tasks related to mobility and the characteristics of urban and peripheral regions to collect points and reach the next level. The game is a mixture of quizzes, identification of the player with a role and simulations. Based on teachers' suggestions, the game was subdivided into two parts to allow the game to be played in portions of one or two teaching units. In accordance with the Citizen Science approach two phases of in-class workshops with feedback from students and teachers were conducted.

The first part starts with the player in the role of a schoolchild living in a small village. The village has a primary school and a small shop. A supermarket and a cinema are located in the district town, about ten kilometres away. The player has to answer (quiz) questions regarding topics like periphery, basic needs, accessibility, urban sprawl, etc. to reach the next level. In following levels, the player commutes to secondary school, moves to the capital to study, starts working and moves back to the countryside when founding a family. At this level, the player engages in local politics to stop the greenfield development of a shopping centre. In the final level of part one the player runs for mayor's office. Feedback on a prototype was obtained from teachers and students of three secondary schools. A total of 91 pupils in four classes tested the prototype in classrooms. The overall feedback was very positive. On a scale from 1 = very bad to 5 = very good the average overall rating was 4.2. The majority saw the game as not too difficult, exciting and useful for learning. About two thirds wanted to play the game again.

In the second part the political career of the player continues. Decisions on municipal level have to be made. Cooperation and compromises with neighbouring municipalities, the federal state and the national government are necessary to achieve environmental and social goals. Simple simulation models are used to mimic real world effects of the player's decisions. Simulation models were programmed using the free, web-based software InsightMaker. The player has to use the simulation models to solve tasks like meeting CO2 reduction goals while keeping the municipal budget balanced. A beta version of the second part was tested in March 2020. Due to the pandemic testing in classrooms was replaced by web-based feedback. Collected feedback shows evidence that the simulation model based part was rather difficult for the target group and not user friendly enough. This can be partly explained by the missing possibility of physical presence and briefing in classrooms. In consequence, teaching material for future classroom application was developed. Nevertheless, the overall rating was still positive and the concept was successful. The game is publicly available for free, in both English and German language: https://ive.boku.ac.at/systemcheck/welcome

Keywords: metropolitan and peripheral regions, system dynamics, educational simulation game, children, mobility

2 BACKGROUND AND MOTIVATION

2.1 Systems thinking and System dynamics

Systems thinking should be a key skill for students as they deal with the complex interrelationships between human actions and natural processes. In Austria as well as in many other European countries, the school education system is characterized by separate subjects. Thus, children mainly learn sectoral expertise. After school, however, children are released into a "real" world that is not characterized by its individual parts, but by complex problems and interrelationships. In order to be able to understand the "real" world, to find one's way and also sustainable solutions for problems and challenges, the ability to think in terms of systems, which is still intuitively given at kindergarten age, must be developed. For this it is essential to be able not only to identify individual elements of a system, but to be able to view a system as a whole (Schnürzler, 2017).

System Dynamics is a method for improving learning in complex systems (Sterman, 2000). It can be used to understand, amongst others, dynamic linkages, identify the causes of policy resistance, and formulate more effective policies. Cause-effect diagrams (causal loop diagrams) as a qualitative method and stock flow modelling as a quantitative method can be used as System Dynamics tools (Arndt, 2016). Cause-effect diagrams can be developed, for example, to qualitatively describe and analyse dynamic systems, such as a core city and its surrounding areas, in a simple way. Stock-flow models can be used to simulate the effects of political decisions or technological changes and thus also to investigate them quantitatively.

There are many topics such as climate change, energy, population development, urbanisation, urban sprawl and resource use which benefit from a systems-based approach. In this context, the holistic analysis of mobility in metropolitan areas and peripheries and its effects is a particularly exciting field of application, since a direct link to students' own experiences and observable processes in their direct environment can be established.

2.2 The problem of urban sprawl and congestion

The term urban sprawl or suburban sprawl refers to "low-density automobile-oriented settlement patterns with little comprehensive public planning" (Bruegmann, 2015). In contrast to a compact settlement development, the phenomenon of "urban sprawl" is associated with numerous negative effects. This refers to negative ecological effects, transport related effects as well as social and health effects (Siedentop, 2005).

Lower property prices and the promise of a calm and green living environment in mono functional suburban regions cause people to move out of the city although most of the jobs and higher educational facilities stay located there, resulting in longer commuting distances. If the public transport supply is low, this promotes car dependent life styles and with increasing car mileage also congestion (and related negative effects such as increased travel time, cost, and pollution).

Overall, the interaction between a core city and its peripheral regions, or respectively transport (accessibility) and space, are very complex issues. In more detail, the causes and effects of population distribution (e.g., migration, traffic impacts, environmental effects) are very difficult to understand and to assess. In addition to this, also the effects of transportation and land use planning measures to limit sprawl and environmental impacts are hard to predict and it usually takes a long time until changes come into effect. Furthermore, dealing with the issue of urban sprawl requires the consideration of many different relevant actors. This clearly shows that, as a result, it is difficult to adequately convey this topic to children and young adolescents in order to foster their understanding of these general processes as well as of their own choices with regard to transport and place of residence.

In the past, scientists made use of the methods of systems thinking and System Dynamics to analyse, visualise and communicate complex interrelations between the transport and the land use system. Causal loop diagrams have been used to qualitatively analyse phenomena like congestion, urban sprawl and the concentration of shopping centres in the periphery of functional urban regions (Pfaffenbichler, 2001a, 2001b, 2011). System Dynamics-based simulation models have been developed for quantitative prediction of the effects of transportation and land use planning policies (Pfaffenbichler et al. 2010, Shepherd, 2014). While for non-experts these models are too complex and not user-friendly enough, simplified versions could be part of educational games and support the understanding of complex system behaviour.

On this basis, the aim of the new teaching and learning tool is to arouse the learners' interest in systems thinking through a playful approach to the topics of mobility and transport, conurbation and periphery, environment, resources and politics. By using the final product, the learners should acquire competences in the field of systems thinking and at the same time learn about central topics of the subject geography and economics about life in urban areas, the interactions between urban areas and their periphery and how people shape their living space.

3 THE SYSTEMCHECK EDUCATIONAL GAME

Educational games promote the development of cognitive, spatial and motor skills and can be used to teach facts (e.g. knowledge, retrieval, memorization, retention of knowledge), principles (e.g. cause-and-effect relationships) and complex problem solving (Felicia, 2009; Boyle et al., 2016).

Systemcheck was developed in 2019-2020 as an interactive, digital teaching and learning game based on simulations of social and ecological effects of mobility and transport in metropolitan and peripheral regions. It was developed and tested in classrooms in close cooperation with two secondary schools in the city of Vienna. For the evaluation, other schools were involved as well. The game specifically addresses topics of the Austrian 6th grade syllabus for the subject geography and economics. The main objective of the game was, on the one hand, to enable students to learn and practise geography subject matters and on the other hand to develop systemic thinking skills. The game should (i) build on children’s everyday life experiences, (ii) cover different topics across school subjects and (iii) be motivating and fun as well.

The basic framework of the multi-level game is the vita of a person, starting in primary school and going through to adulthood. Players of the game have to solve different tasks related to the mobility of people of different age cohorts living in urban and peripheral regions. Points are collected in each level if tasks are solved correctly. The game is a mixture of quizzes, identification of the player with a role and simulations. Based on teachers’ suggestions, the game was subdivided into two parts to allow it to be played in portions of one or two teaching units. The first part covers the time span from childhood to early adulthood ending with the player becoming mayor of a medium sized town. This part consists of different types of quizzes. The second part deals with the political career of the player and is made up by simulations. The game is publicly available for free in both English and German language via the following link: https://ive.boku.ac.at/systemcheck/welcome

3.1 First part of the game

At the very beginning, the player has to decide whether to choose a female or male character for the game. Then the game starts with the player in the role of a schoolchild living in a small village. The village has a primary school and a small shop. A supermarket and a cinema are located in the district town, about ten kilometres away. The player has to answer (quiz) questions regarding topics like periphery, basic needs, accessibility, urban sprawl, etc. to reach the next level. In following levels, the player commutes to secondary school, moves to the capital to study, starts working and finally moves back to the countryside when founding a family. At this level, the player engages in local politics to stop the greenfield development of a shopping centre. In the final level of part one the player runs for mayor’s office.

Figure 1 shows a screenshot of the introduction into the level “Work in the Big City”. Each level is introduced with a colourful cartoon symbolising the life stage and living environment of the player and some explanatory text. The introduction is followed by a series of quiz questions. Figure 2 shows a screenshot of such a question. Selecting the correct answer at the first attempt is granted with four points. If the answer is not correct players have the option to modify their choice. Finding the correct answer with the second attempt is granted two points. If the answer is still incorrect, the correct answer is displayed together with a text that provides an explanation, why certain answers are correct and others are not. The answers then are randomly mixed and the player has to find the correct answers again, in order to encourage that the explanation is read and to promote learning. No points are awarded for correct answers once the solution has been displayed. This evaluation scheme should avoid a trial and error strategy by the children. In addition, multiple answers are possible and given answers are randomly mixed.

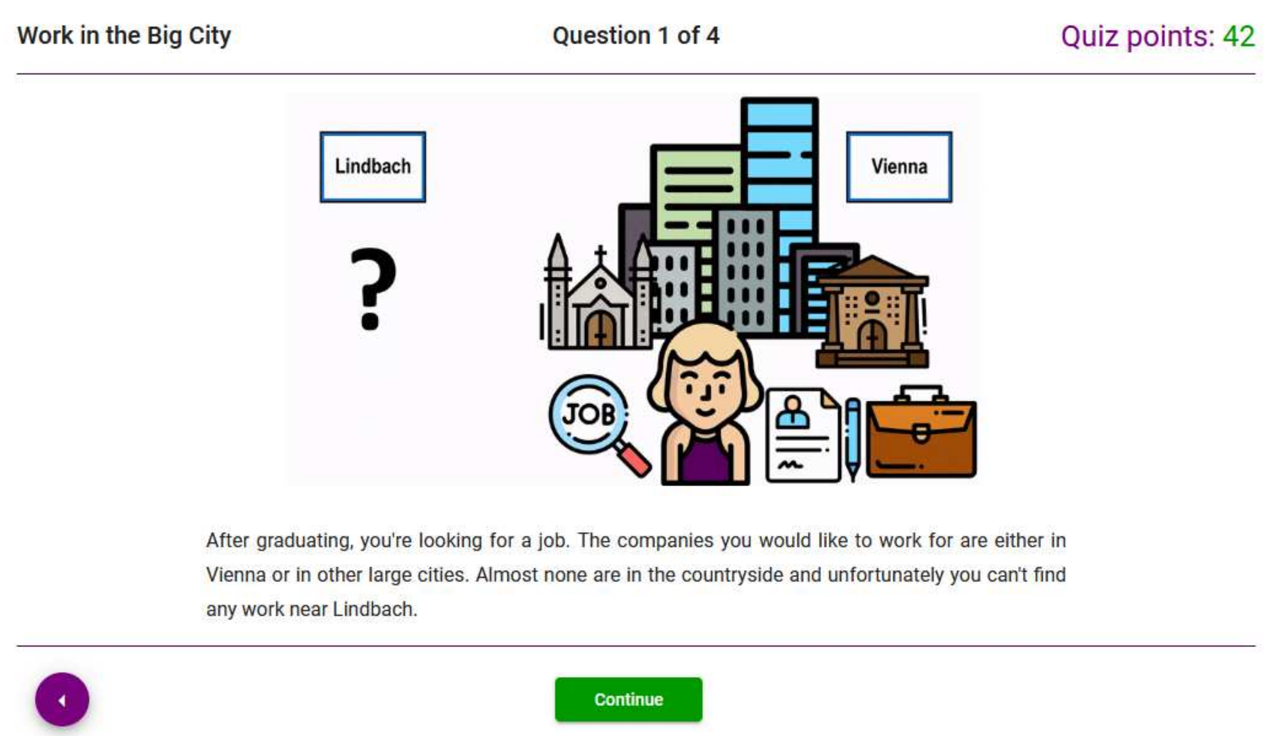

Fig. 1: Screenshot of the level "Work in the Big City" of part 1 of the educational game Systemcheck

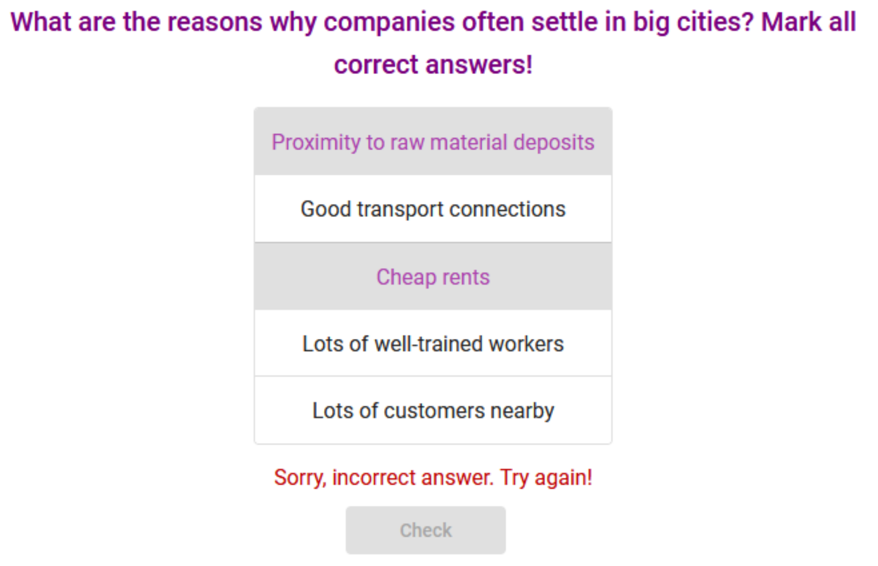

Fig. 2: Screenshot of the 1st quiz question of the level "Work in the BigCity" of part 1 of the educational game Systemcheck

3.2 Second part of the game

In the second part the political career of the player continues. Decisions on municipal level have to be made. Cooperation and compromises with neighbouring municipalities, the federal state and the national government are necessary to achieve environmental and social goals. Simple simulation models are used to mimic real world effects of the player's decisions. Simulation models were programmed using the free, web-based software InsightMaker (www.insightmaker.com). The player has to use the simulation models to solve tasks like meeting CO2 reduction goals while keeping the municipal budget balanced. The models are white box models, so the players could take a look at the parameters and equations behind them, even though without further instruction by teachers this is unlikely the case. Players can experiment with the models as often as they like before submitting an answer. A playful trial and error strategy is encouraged in this part of the game.

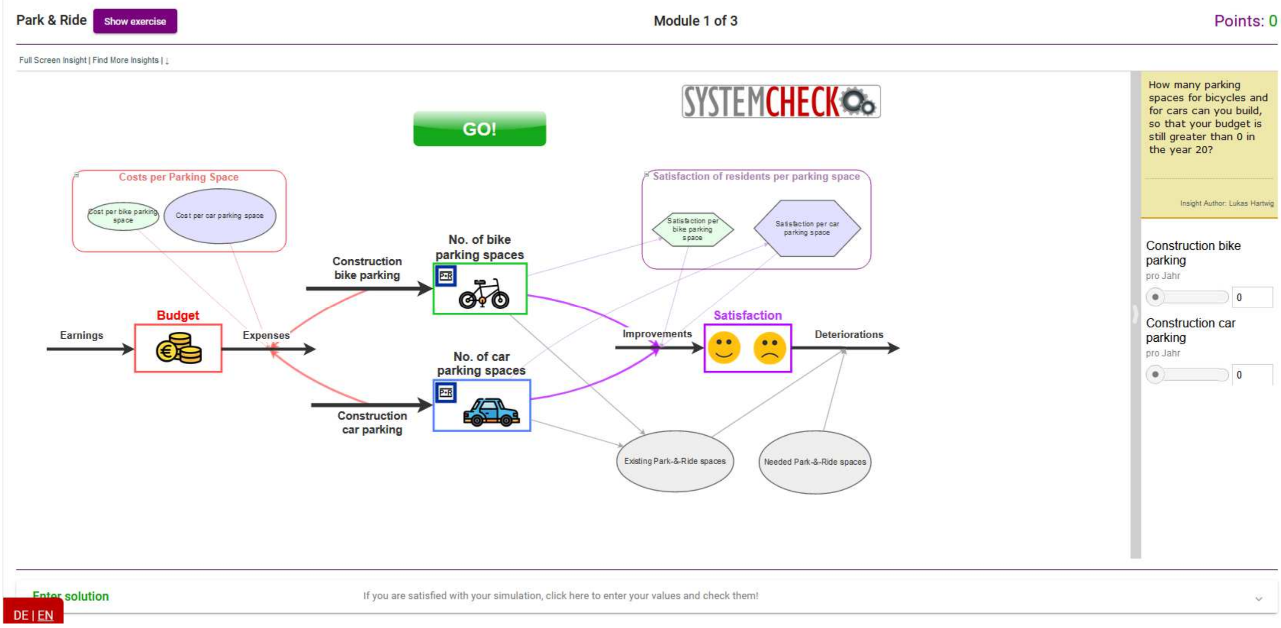

Fig. 3: Screenshot Insightmaker simulation “Park & Ride” of part 2 of the educational game Systemcheck

4 TESTING THE GAME

In accordance with the Citizen Science approach, several feedback loops were conducted to involve students as well as teachers in the development of the game.

In a first phase, feedback on a prototype of the first quiz-based part of the game was obtained in 2019 from teachers and students of the two project partner schools and a third secondary school. The feedback was collected in open feedback rounds in class (teachers, students), observations (of students while playing the game), and with the help of written questionnaires (students). A total of 91 pupils in four classes tested the prototype in classrooms. Ideas for improvements were collected and implemented as far as possible. For example, definitions are given as mouse-over text for important core terms of the game. In addition, explanations are given as feedback in case that incorrect quiz answers were given by the students to promote the learning effect. The beta version of the complete game including the second simulation-based part was tested in March 2020. Due to the pandemic, further testing in classrooms had to be replaced by feedback via a web-based questionnaire. In total 128 persons tested the quiz-based part only and 101 people tested both parts of the game.

The overall feedback was very positive. On a five-point-scale from 1 = very bad to 5 = very good the average overall rating was 4.2. The majority saw the game as not too difficult, exciting and useful for learning. About two thirds wanted to play the game again. The possibility to get into a character and go through the different stages of life was highlighted by the students in the workshops as an interesting feature. Nevertheless, there is a significant difference in the overall rating of people who played only the first part and people who played both parts (Figure 4). About 86% of the people playing only the first part rated the game as good or very good. In the group playing both parts this share is reduced to about 63%. This gives first evidence that the second, simulation-based part might be too difficult or not user-friendly enough. A detailed analysis of the collected feedback supports this finding. Figure 5 shows the feedback on the question about the difficulty of the game of the sample playing both parts of the game. While 27% of respondents say that the difficulty of the first part is appropriate, only 21% think the same for the second part. The percentage of those who think the game is easy drops from 35% to 6%. On the other hand, the share of those who think the game is difficult increases from 11% to 45%. The share of those who think the game is very difficult even increases from 3% to 25%. Hence, we have to conclude that the simulation part was rather difficult, especially for the target group, and not user-friendly enough. The low rating might partly be explained by the missing possibility of physical presence and briefing in classrooms. Nevertheless, there is a strong need for improvement of the simulation-based model part. But, the overall rating was still positive and the proof of concept was therefore successful.

Due to limited resources, further revision of the simulation-based part or the development of a simulation tutorial was not possible within the project. As a temporary fix, extensive teaching material was developed that can be used for briefing before and de-briefing after the game is played. Teaching experience with other learning games in an university context highlights the importance of collective reflection in a de-briefing session for the players' learning effect.

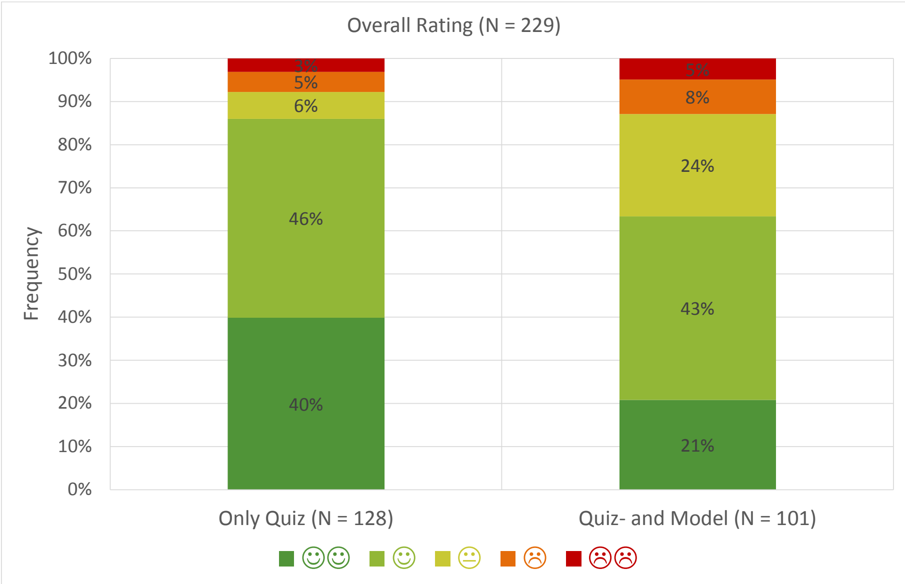

Fig. 4: Overall rating of the educational game Systemcheck

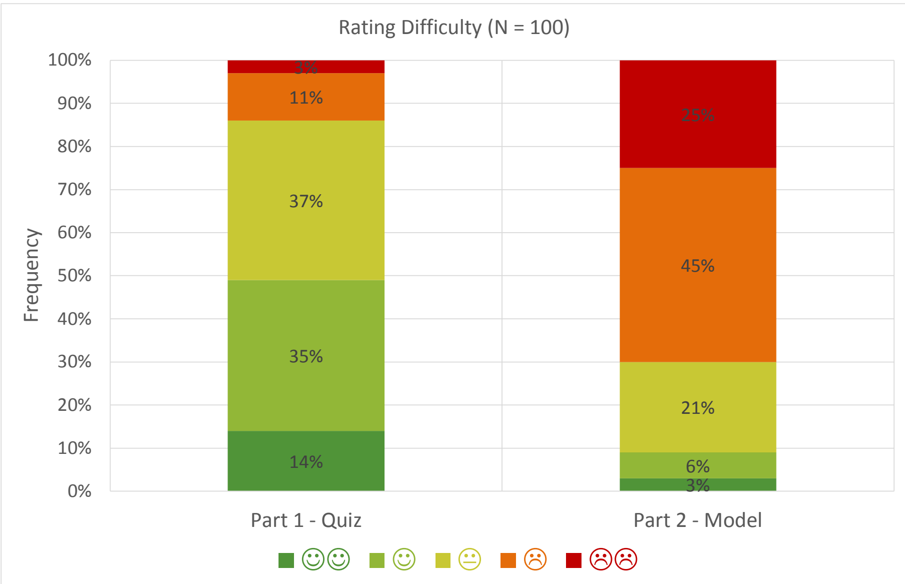

Fig. 5: Rating of the difficulty of the two parts of the educational game Systemcheck

5 CONCLUSION AND OUTLOOK

The multi-step approach of involving teachers and students of different schools to test and develop the digital game proved to be very successful. Due to the pandemic and related measures it was, unfortunately, not possible to conduct more feedback loops and evaluations with the cooperating schools. However, the overall feedback was very positive both from teaching staff and from students. The students thought it was good to get into character and go through the different stages of life. There is, however, strong evidence that the simulation model-based part was too difficult and not user-friendly enough. This can be attributed to several reasons: For example, programming required higher efforts than expected. Hence, resources had to be shifted and were not available for the simulation model design. In addition, the incorporation of InsightMaker into the game could not be realised as seamlessly as intended, so design options were limited. There was also the requirement to keep the game short and concise, so that it each part could be played in one teaching unit. This meant that we decided against tutorials and lengthy introductions. As a result, the simulation games were not as intuitively understandable as planned. More effort on this issue is needed for revised future versions of the game.

There are still many ideas for future adaptations and endless possibilities of extending the digital learning game. Further fields of application are seen in the education of university students; new target groups require further adaptations. Based on the German version of the game, an English version was developed with the help of the prize money (BOKU Sustainability Award 2020 in the category "Education for Sustainable Development”) and is also freely available. An evaluation of the effect of improving system thinking among different target groups would be an interesting future challenge. Regardless of the challenge of further adaptations, authors are enthusiastic about the potential of the gaming approach and very keen to continue the work on educational games and are looking for co-operation partners!

6 ACKNOWLEDGEMENTS

The project Systemcheck was funded in the 2nd call of the programme “Förderprogramm Erstellung von digitalen Lehr- und Lernmitteln mit Citizen Science-Methoden“ by “Die Innovationsstiftung für Bildung”. The programme was managed by OeAD-GmbH.

We would like to thank the teachers Nikola Kappelmüller, Susanne Ottenfels (Lise Meitner Realgymnasium), Manuel Hummel (Brigittenauer Gymnasium), Elisabeth Weixlbaumer (NMS Gunskirchen) and our student assistant Karina Anderl for their support in the project Systemcheck.

We would furthermore like to thank our students Lea Giora Helfer, Julia Hofer, Michael Straninger and Sonja Witz from the Interdisciplinary Project of the bachelor program "Environment and Bio-Resources Management“ for their invaluable contribution to this work.

Thanks also to Philipp Weixlbaumer for programming the game.

Mobility Inequality in a Small Town in Central Poland. The Case Study of Zgierz

Bartłomiej Olczak

(MSc E. Bartłomiej Olczak, Lodz University of Technology, Staffa 1/38 95-100 Zgierz, bartlomiej.olczak.1@dokt.p.lodz.pl)

1 ABSTRACT

Over the past decades, the number of cars has been increasing around the world rapidly. In effect, the demand for road space and space for parking has also been growing. At the same time, especially in town centres, space is limited, which leads to many urban conflicts.

Our cities are automobile-dependent, which means that transportation and land use patterns favour car users and at the same time create less accessible circumstances for other means of transport, particularly for pedestrians and cyclists. It excludes vulnerable and marginalised groups and harms the majority of inhabitants.

There is a need for a different distribution of the forms of mobility, in particular in terms of sustainable development and climate change mitigation.

It finds confirmation in many European agreements. The European Union has been dealing with sustainable development and mobility for several years. The results of it are the Green and White Papers. The newest documents like the European Green Deal and the New Leipzig Charter focus on sustainable transformation, which leads to climate neutrality. The main aim is to make cities inclusive, safe, resilient, and sustainable. It also concerns the topic of urban mobility.

In Poland, transport problems began to increase in the second half of the 20th century. The transition to a market economy led to the decapitalization of transport networks. As a result, differences between regions increased and the accessibility of many areas in the national and European systems deteriorated. The problem concerns especially small towns, where the resignation from public transport is common. and leads to exclusion.

Zgierz is a town located in central Poland, in the vicinity of Lodz, the third-largest city in the country. Due to the collapse of the textile and chemical industries, Zgierz faced the need to transform its economic profile, which it has not dealt with yet. Moreover, the negative impact of transportation compounds the effect of the degradation. The problem is the most visible in the centre area due to the radial layout of streets and the lack of ring roads.

This study examines the negative impact of transport and mobility inequality in a small town in Poland. Using the case study method it identifies diverse aspects in which users of different means of transport are not treated equally. It analyses traffic congestion, demand for space, barriers in public spaces, road safety and air pollution. It also compares the results of analyses with European guidelines and offers some key recommendations.

Keywords: sustainable development, mobility inequality, urban mobility, climate change, small town

2 INTRODUCTION

The need for inclusive, safe, resilient, and sustainable cities is emphasised in the 2030 Agenda for Sustainable Development. Overcoming mobility inequalities is connected to at least 4 of 17 set goals – good health and well-being (SDG 3), gender equality (SDG 5), reduced inequalities (SDG 10) and sustainable cities and communities (SDG 11). It also finds confirmation in many other documents, such as the New Urban Agenda, the Paris Agreement, the European Commission's Green Deal and the New Leipzig Charter. In order to achieve the set goals, the need for a better understanding of mobility inequality is one of the critical elements.

In Poland, transport problems began to increase in the second half of the 20th century. The transition to a market economy led to the decapitalization of transport networks. As a result, differences between regions increased and the accessibility to many areas in the national and European systems deteriorated. Also, due to the technical condition of regional roads and tracks, the accessibility to public services worsened. The problem particularly concerns small towns, where the resignation from public transport is common and leads to exclusion (Koncepcja Przestrzennego Zagospodarowania Kraju, 2012).

Despite the collapse in the early 1990s and the lack of investment, the mobility and transport of goods increased. As a result, the environment and road infrastructure suffered and the number of accidents increased. The more environmentally-friendly railway has also lost its position. It is no longer a competition for road transport. Moreover, the independent development of individual forms of transport led to the lack of connections between them (Koncepcja Przestrzennego Zagospodarowania Kraju, 2012).

Year	2000	2005	2010	2015
The average daily annual traffic of motor vehicles	7009	8244	9888	11178

Table 1: The average daily annual traffic of motor vehicles on national and voivodeship roads. Source: own table based on Generalny Pomiar Ruchu.

Based on the data collected by the General Directorate for National Roads and Motorways, during the General Traffic Measurement carried out every five years, it is possible to observe the traffic intensity on national and voivodeship roads. In 2015, the average daily annual traffic of motor vehicles was 11,178 vehicles/day, 13% higher than in 2010. The most significant increase in traffic was among trucks with trailers (18%), passenger cars (17%) and motorcycles (15%). In 2010-2015, there was an increase in traffic on national roads in all voivodeships. However, the highest was recorded in the Lodzkie Voivodship, by 26%. These changes were caused not only by the actual increase in traffic but also due to the construction of new road sections such as the A1, A2 motorways or the S8 expressway (Generalny Pomiar Ruchu, 2016).

3 METHODOLOGY

Case study research helps to understand reality, which is nuanced and based in a concrete context. Some processes, especially connected to human behaviour, cannot be described as predictive theories and universals (Flyvbjerg, 2006). The most considerable value of this method is giving special attention to what has actually happened in a given setting and how. This method has a practical value for practitioners, providing data and understanding complex urban processes and relations (Duminy, 2015).

This study adopts a case study method approach to investigate and better understand processes connected to transport patterns leading to mobility inequalities in a small town in central Poland against the backdrop of international documents mentioned above. The first part of the research describes specific conditions in Zgierz, such as spatial structure and road layout. After that, considerations on the consequences of the current situation and the associated nuisances contributing to mobility inequality were discussed. Direct factors such as congestion, land consumption, spatial barriers, safety and air pollution were considered. Based on the available materials related to the conditions in the town, such as reports, databases and thematic maps, and observations and field inventory results, an assessment was made of the impact of transport on mobility inequality in Zgierz. The final part of this study includes conclusions of the findings and some key recommendations.

4 CASE STUDY

4.1 About Zgierz

Zgierz is a town located in central Poland, in the neighbourhood of Lodz, the third-largest city in the country. Due to the collapse of the textile and chemical industries, Zgierz faced the need to transform its economic profile, which it has not dealt with yet. As a result, many post-industrial areas located in the centre are currently unused and contribute to decreased attractiveness. Besides, the negative impact of transportation compounds the effect of the degradation. The problem is mostly visible in the centre area due to the radial layout of streets and the lack of ring roads. The cars' domination in urban space contributes to the aggravation of negative phenomena and prevents the proper functioning of the centre of Zgierz, leading to its collapse.

4.1.1 The road system

The road system in Zgierz is the result of historical connections with neighbouring cities. They form a radial network, the meeting point of which is the town centre (Figure 1). The lack of ring roads and the radial layout makes it necessary to drive through the centre each time, regardless of the destination. It leads to the accumulation of negative impact of transport in the historical part of the town and puts pressure on the environment.

One of the main problems of the transport system in Zgierz is that main national roads run through the town and cross each other in the centre. At the same time, they are one of the most congested roads in Poland. The possibilities of transformation are limited due to external factors, such as road parameters regulations, as well as internal ones, such as the historic urban layout and the current investment. Furthermore, rebuilding these roads would not significantly improve their functioning or eliminate their negative impact (Studium, 2015).

The construction of the bypass system is seen as a solution to a conflict situation. The already completed A1 motorway and the planned S-14 expressway could successfully transfer transit traffic currently running along national roads through the town centre. This situation would allow to adjust the rank and class to the current parameters and adapt to the streets' character in the town centre (Studium, 2015).

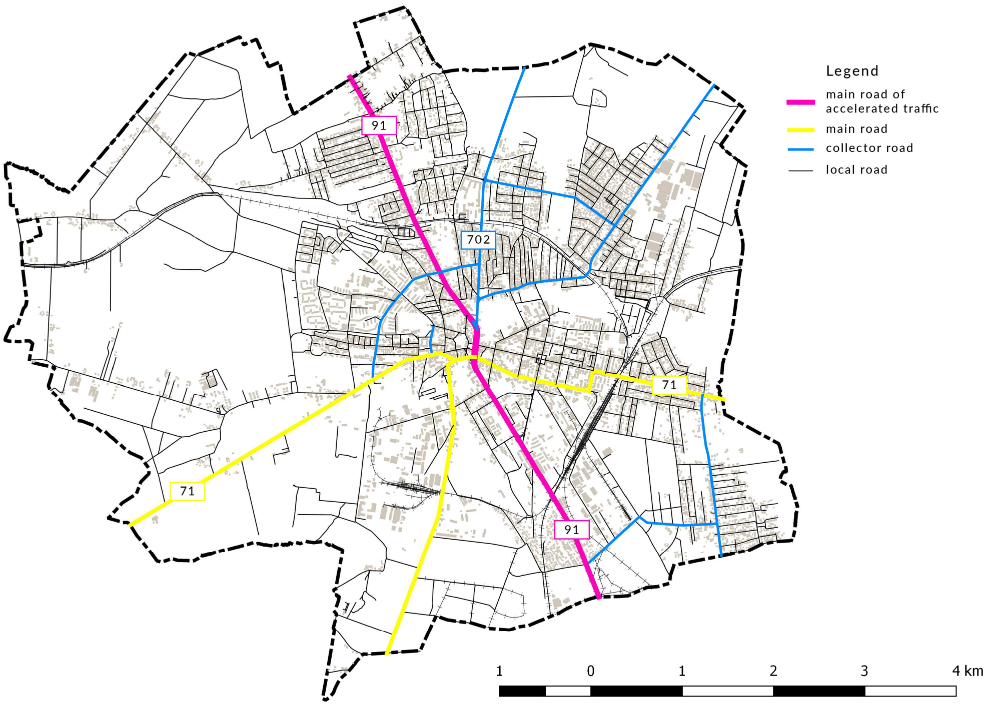

Fig. 1: Road classes in Zgierz. Source: (Olczak, 2019) based on (Studium, 2015) and (Geoportal Województwa Łódzkiego).

In Zgierz, the General Traffic Measurement is the only current source of information about the number of vehicles on the road. Due to the fact that both national roads as well as the only voivodeship road run and intersect in the very centre of town, this gives a certain picture of the traffic intensity.

Measuring point	Road number	Number of vehicles			
		2000	2005	2010	2015
1	91	19213	18684	19980	18114
2	91	24725	26185	25551	27641
3	71	-	11229	11430	11093
4	71	3176	3998	5617	7977
5	702	-	-	17447	16751

Table 2: Average daily annual traffic at measuring points on national and voivodeship roads running through Zgierz in 2000-2015. Source: own table based on Generalny Pomiar Ruchu.

The above data (Table 2) shows that the national road No. 91 has been the most heavily burdened by traffic for many years. Additionally, the traffic on this route has been constantly increasing. Moreover, on the route from Aleksandrów Łódzki (national road No. 71), the number of vehicles has increased by 42% in 2010-2015. In other cases, the traffic was reduced by a few percent. Far more vehicles travel north-south on national road No. 91 than east-west on national road No. 71.

The dominant means of transport on all the routes studied were passenger cars (Table 3), which accounted for over 80% of all vehicles. A significant group on the route to Aleksandrów Łódzki (measuring point 4) were lorries with trailers, their share at the level of over 17%. A comparable value was also recorded on the national road No. 91 at the measuring point 1 – over¬ 10%. In the remaining cases, both lorries with and

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

without trailers accounted for a few percent of the share (about 1-6%). Light trucks (delivery vans) constituted a significant group of a few percent share (about 5-10%). Among the other means of transport, a small share, less than a percentage, was recorded.

Measuring point (Road number)		1 (91)		2 (91)		3 (71)		4 (71)		5 (702)	
Motorcycles		64	0,35%	128	0,46%	48	0,43%	21	0,26%	117	0,70%
Passenger cars		14540	80,27%	23203	83,94%	8945	80,64%	5496	68,90%	14272	85,20%
Light trucks		1268	7,00%	1712	6,19%	1024	9,23%	652	8,17%	938	5,60%

4.1.2 Urban structure

The town centre of Zgierz consists of two-parts – historical with buildings from the beginning of the 19th century and historic urban layout and a modern one with blocks of flats. The axis of the entire downtown layout is Długa Street, along which a large part of public institutions and various services are located (Studium, p. 97).

An essential element of the urban structure of Zgierz is also the 650th Anniversary Housing Estate located to the west from the town centre. It is inhabited by nearly 40% of all inhabitants of the town and is a competitive area for the town centre.

A huge problem of the town centre is the lack of a coherent spatial structure and gaps in development. The value of the areas in the centre and the sense of identity are too low to counteract the deconcentration and the progressive urban sprawl effectively. The urbanisation process is incredibly intensive in the northern, northeastern and eastern parts of the town (Studium, 2015, p. 93). There is also no intention to intensify the use of the centre. One of the reasons may be the growing demand for space dedicated to cars and habits of both decision-making groups and the residents, which oppose any attempts to limit the availability of cars (Wesołowski, 2008, p. 40).

The designation of new non-urbanised areas for development planned in the Studium may contribute to further progress of the suburbanisation process. Consequently, it leads to deterioration in the accessibility of services and transport, and thus the dependence on cars of the inhabitants of peripheral areas.

5 INEQUALITIES

5.1 Automobile dependency

This term refers to transport and land-use patterns that are privileging car users and at the same time creating less accessible circumstances for other means of transport, especially pedestrians and cyclists (Victoria Transport Policy Institute, 2016). Shopping centres are a great example of this problem but it also applies to municipal offices.

In Zgierz, most offices and institutions (66,7%) are located in the town centre (Figure 2). Therefore they are available to motorists, pedestrians, cyclists and public transport users. However, some objects of this type (33,3%) are located further from the centre. Their surroundings do not indicate that it is an essential public facility. In their vicinity, extensive single-family housing, industrial facilities, and even open areas are located. Reaching these offices by public transport is significantly tricky because they are located further from main roads and only low-frequency buses stop in the area. However, parking spaces are provided for each of them. Moreover, these offices are at great distances from each other.

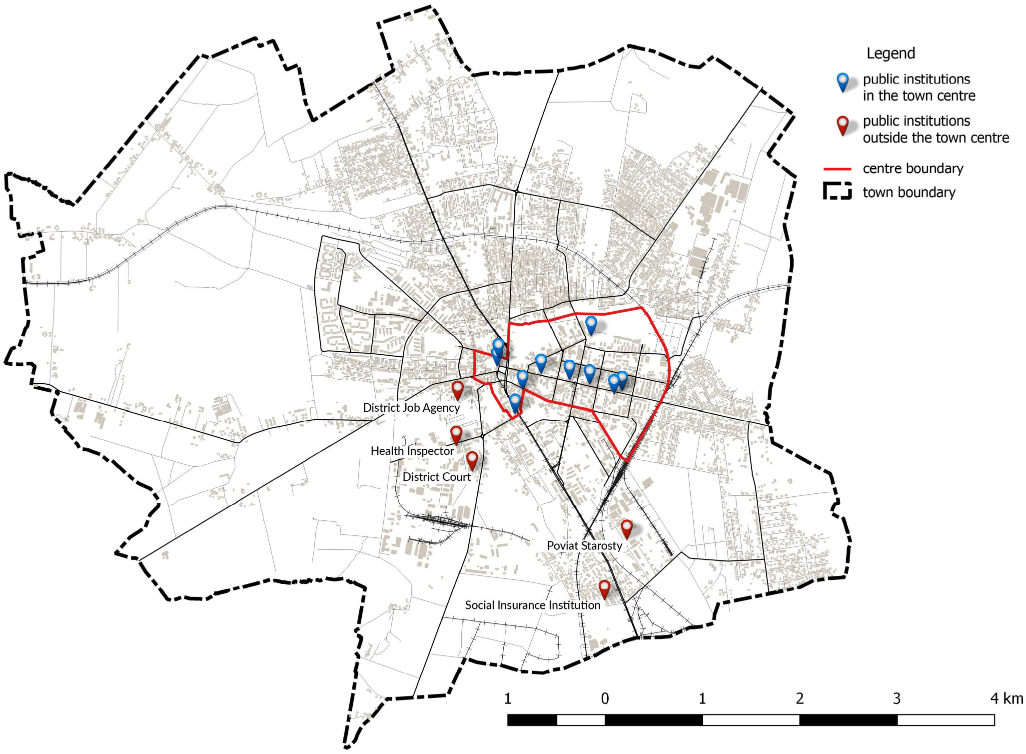

Fig. 2: Location of public institutions in Zgierz. Source: (Olczak, 2019).

5.2 Demand for space

The demand for road space and space for parking is growing. At the same time, space is limited, especially in town centres. Dedicating this much space to cars is a very ineffective way of land use because cars are only actively used for a minimal time and, in most cases, only by one person. Due to limited parking space, car users leave their vehicles on pavements, lawns or crosswalks. Space dedicated to pedestrians or cyclists, which is very limited right now, is even more reduced. Inequality in space distribution is a big problem in towns. Especially in town centres, it is crucial to allocate space in favour of efficient transportation.

5.2.1 Parking space

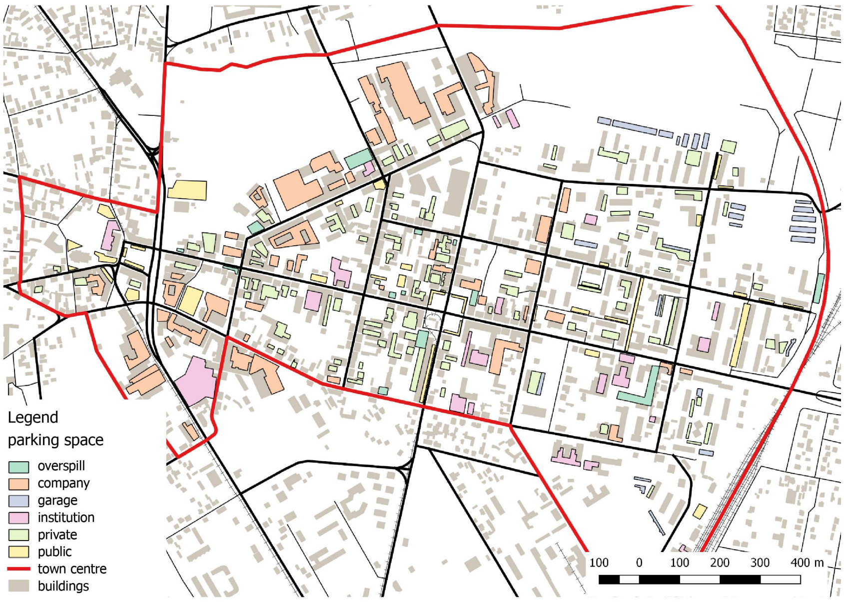

Fig. 3: Parking space in the centre of Zgierz. Source: (Olczak, 2019).

The biggest problem with parking in Zgierz is the area it occupies and the way it is organised. In addition, drivers appropriate space to park illegally in places not intended for this, such as lawns or pavements. In many locations where cars are parked, there should be buildings or greenery.

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

The pavements are also occupied by cars, making it difficult for pedestrians. Often this is the case with wide streets with little traffic, where parking space could be located within the street. However, the lack of designated places leads to cars parked in the space dedicated to pedestrians.

Additionally, the lack of a parking policy contributes to the escalation of the problem in the centre of Zgierz. Parking in the entire town is free, which only encourages the use of cars. Moreover, the lack of reaction to illegal parking on pavements or undeveloped plots gives drivers a sense of quiet consent.

5.2.2 Roads

Roads in the town centre also occupy a significant area. According to the law, the maximum width for roads class Z, L and D can be broadened to 3.50 m if it results from the traffic forecast. The regulation also allows reducing by 0.25 m the values given in the table for traffic calming. However, in Poland, it is common that roads have the maximum permissible width of lanes, and often even wider ones, regardless of their class or traffic intensity.

Road class	GP and G	Z	L	D
Minimal width of lane	3,50 m	3,00 m	2,75 m	2,50 m

Table 4: Minimal width of lane. Source: own table based on Rozporządzenie.

In addition, the space dedicated to cars is not fully used. In many places, despite the broad streets, parking takes place entirely or partially on sidewalks, additionally appropriating the space intended for pedestrians.

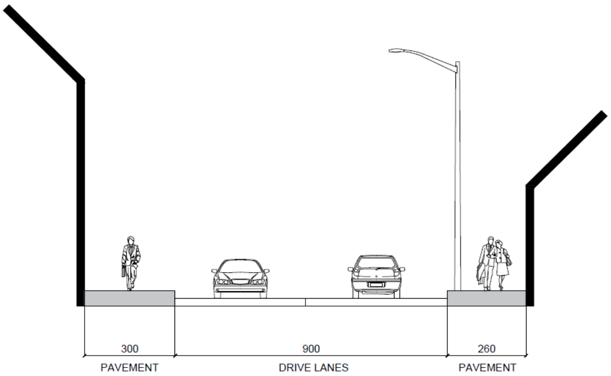

Fig. 4: Street section – Długa street in Zgierz. Source: (Olczak, 2019).

Długa Street (Figure 4), which is the representative space of the town, is 9 m wide, thus significantly exceeding the norms specified in the regulation. There are two lanes within the road and nothing else. However, the width would allow for the separation of parking spaces, greenery or bicycle lanes. The pavements on Długa Street are relatively wide, but there is often infrastructure such as lamps or road signs, which reduce the space on some fragments. Additionally, the pavement space is often occupied by parked cars.

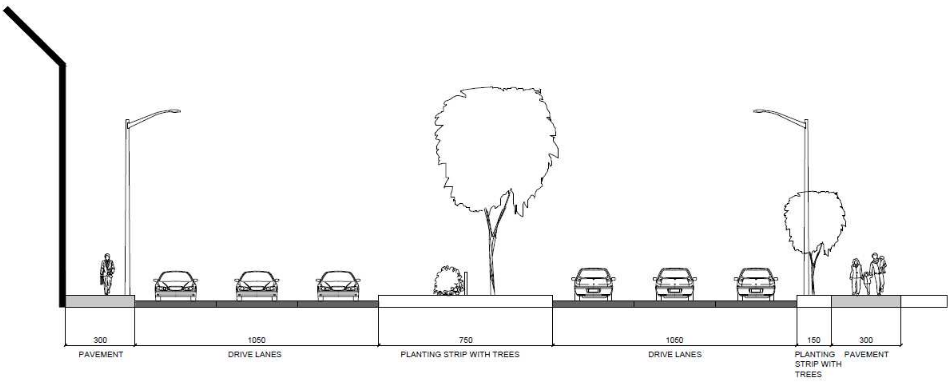

Fig. 5: Street section – the national road no. 91 in Zgierz. Source: (Olczak, 2019).

It is also worth paying attention to the national road no 91 (Figure 5), which runs through the town centre, cutting it into two parts. At the town entrances, both from the south (towards Łódź) and the north (towards Gdańsk), it has a single carriageway with two lanes. In the vicinity of the centre, it widens to 4 lanes, 2 in each direction. The section running directly through the centre has a 2x2 section – 2 roadways with two lanes each. In addition, there are also left-turn lanes and a green belt, which separates both roadways. The road covers a large area and is a spatial barrier that separates the town's structure. It cuts the centre into two separate entities, leaving them unconnected. In addition, due to its width and traffic congestion, this road is an obstacle for pedestrian traffic. To get to the other side of the road, pedestrians have to cover about 30 m. Also, other roads in the centre are barriers to pedestrian traffic. Although their parameters are much smaller – 1x2 (one road with two lanes), they are still very broad (8-9 m wide) and the traffic congestion is very high.

5.3 Road safety

In 2016, 3,026 people died on Polish roads, which accounted for almost 12% of all victims in the European Union. Poland is therefore one of the leading countries, with the highest number of deaths. In addition, the following countries on the list have over a thousand deaths less. (CARE database). In 2015, 915 pedestrians died on Polish roads. Although within ten years (2006-2015) this number has been reduced by half, Poland is still in the infamous first place among the European Union countries, overtaking other countries by nearly 300 victims. Also, with regard to cyclists, Poland ranked high, with the number of victims of 300 in 2015, overtaken only by Denmark (European Road Safety Observatory, 2017).

Almost 87% of road incidents in Zgierz are the fault of the vehicle driver. In addition, they are responsible for 69% of the deaths, 78% of the seriously injured and 85% of the lightly injured. Apart from vehicle collisions, collisions with pedestrians are the most common type of event - 480 events. Many accidents also occur at pedestrian crossings. Moreover, failure to prioritise pedestrians is the most common cause of fatal accidents and severe and slight injuries (SEWiK).

In Zgierz, pedestrians are the largest group of fatalities and are more likely to be severely injured in accidents. The most significant number of deaths among pedestrians was recorded in the over 50 age group, and especially in the over 70 group. In turn, fatalities among vehicle drivers are much younger – under 40 years of age (SEWiK).

The most dangerous roads are located in the town centre. Although the most significant number of incidents (Figure 6) takes place on Łódzka Street (61% more incidents than on Długa Street), the most significant number of victims was recorded on Długa Street (46% more injured than on Łódzka Street). The representative Zgierz street leads in terms of the number of injured, lightly and severely, and fatalities. In addition, the number of casualties significantly exceeds the figures recorded in other streets - 36% more lightly injured and 78% more seriously injured than on the second-ranked streets (SEWiK).

If we look at pedestrian safety (Figure 7), the most significant number of pedestrian incidents also occur in the town centre. Pedestrians were about 50% of all victims (Długa Street - 56.4% and 1 Maja Street - 46.2%) (SEWiK).

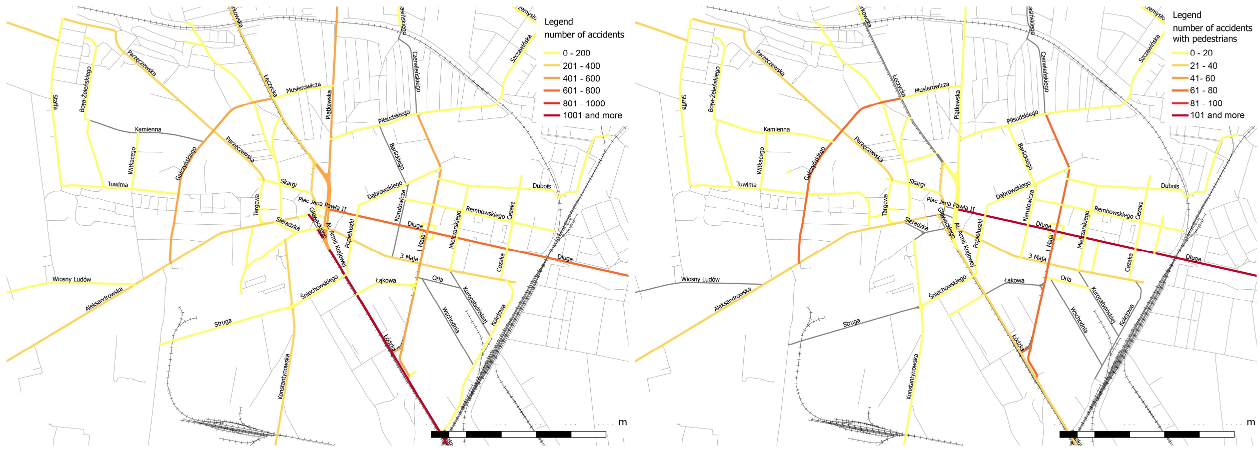

Fig. 6-7: The number of car accidents in total (left) and with pedestrians' involvement (right) in Zgierz in 2007-2017. Source: (Olczak, 2019) based on (SEWiK).

5.4 Air quality

The monitoring results clearly show the growing impact of road transport on the deteriorating air condition. When looking at the reports from the only measuring station in Zgierz (Figure 10) and comparing the PM10

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

and PM 2,5 measurement results with Polish (solid line) and European standards (dashed line) (Figure 8-9), significant discrepancies can be noticed. If national limit values are used, bad or very bad air condition is recorded only a few times a year. On this basis, it can be concluded that air pollution in Zgierz is not severe. However, according to European standards, the situation in the town is much worse again. Transgressions are recorded for a significant part of the year. This means that residents breathe poor or very poor quality air most of the time, which can pose a severe health risk, especially to children, the elderly, and pregnant women.

It should also be emphasised that the measuring station is located in the eastern part of the town centre, surrounded by blocks of flats, at a considerable distance from the roads with the highest traffic. This may translate into incomplete accounting for pollutants of transport origin. Therefore, it should be assumed that the actual air pollution near roads may be significantly higher.

6 DISCUSSION

6.1 Automobile dependency

The location of offices in Zgierz is in contradiction with the idea of the compact city. The dispersion of public administration facilities beyond central areas limits individual transport mobility options. For a person who does not have a car and has several official matters to deal with in one day, the route between the facilities can be challenging and time-consuming. It creates mobility inequalities and can lead to social exclusion for vulnerable and marginalised groups such as the elderly or disabled people.

6.2 Demand for space

Roads located in the centre of Zgierz are designed in the cars' favour. In effect, it limits transport options for citizens without cars. It is worth paying attention to how unevenly distributed space is to the needs of different traffic users. Pedestrians, cyclists and even public transport users are put in a worse position. Walking between parked cars is a barrier and obstruction to pedestrians, especially for vulnerable groups such as the elderly, disabled people or people with small children. It is also worth noting that vehicles parked on the pavements reduce the visibility of both pedestrians and drivers, which may also increase dangerous situations on the road.

Furthermore, roads, especially those with heavy traffic, are also barriers in spatial and social terms. They are hindering the development of outdoor activities, neighbourly contacts and freedom of movement. Spatial barriers can also have a significant impact on transport decisions made by residents.

The national road No. 91 – Łódzka Street brings the most negative spatial consequences for the central area. It reaches the largest size, occupying a large area, separating the town structure and creating a spatial barrier, mainly for pedestrians.

6.3 Road safety

Road transport is the most dangerous of all of the modes. Even though everyday people are dying or being injured in car accidents, we seem not to see the problem and treat it as a natural consequence of using cars. As a result, car users are more privileged than pedestrians, who are primarily casualties. This situation is also generating costs for the whole society.

It should be emphasised that, contrary to popular belief, the victims of accidents are not usually drunk or invisible pedestrians and cyclists. On the contrary, often children or the elderly are among the victims. Most of the incidents occur mainly during the day on newly built or modernised roads. In the case of pedestrians on sidewalks and crossings, they should theoretically feel safe.

The level of safety on the streets of Zgierz, as in the rest of Poland, is too low. In particular, the unprotected road users, i.e., pedestrians and cyclists, who cannot feel safe even in their designated areas (sidewalks, pedestrian crossings or bicycle lanes), are at risk. Also, the spatial distribution of both the number of incidents and victims indicates that the town centre is the least secure space. On the other hand, road safety also has a massive impact on the choice of means of transport.

It is also worth paying attention to the massive number of events on Długa Street, the town's representative street. It ranks second in terms of the number of accidents in the town but it is also the most dangerous for pedestrians. On the one hand, it plays a vital role in the centre by concentrating the activity of residents. At the same time, there is heavy traffic on it, leading to conflict situations. Undoubtedly, the intensity of traffic on Długa Street and the high risk of an accident translate into unfavourable conditions for other than cars modes of transport.

6.4 Air quality

Based on air quality measurements from the only one station in Zgierz, it can be concluded that the level of pollution in Zgierz poses a severe threat to the health of its inhabitants. Numerous transgressions of the acceptable standards, both European and World Health Organization, and much less restrictive Polish, indicate the need to improve air quality. In particular, more than 40,000 premature deaths occur annually in Poland due to air pollution (European Environment Agency, 2017). Even though cars are responsible for a significant part of the emissions in the urban area, all citizens have to deal with its adverse effects. In this case, individual transport is privileged because we often do not think about external costs connected to it, for example, polluting the air.

6.5 Recommendations

A proven method of achieving equal mobility is using the push-pull method, on the one hand, introducing restrictions primarily for the use of cars, on the other hand, incentives in the form of, e.g., efficient public transport. However, the implementation of the idea of sustainable mobility should be carried out in a balanced way. Choosing a car as a means of transport is supposed to be an option, not a necessity.

Promoting the idea of sustainable mobility should therefore take place through appropriate shaping of transport behaviour. For this purpose, soft transport should be given preference by providing the shortest route for cycling and walking. This means shaping the infrastructure that prioritises users traveling in this way. The advantageous route should also be provided to public transport. However, individual transport should receive the least priority. Such thinking about shaping transport in the city is a manifestation of the push-pull method.

Actions to change the transport behaviour of residents should also be followed by architectural and urban solutions aimed at restoring the original functions of the street, i.e., public space lost as a result of uncontrolled expansion of the car. High-quality and well-functioning public space can also be a form of compensation for limitations in the use of individual transport.

Recommendations and suggestions for improving mobility equality in Zgierz:

- Intensify the development of the centre of Zgierz and limit the urban sprawl.
- Make the location of new buildings dependent on the possibility of using public transport.
- Provide an attractive public space in the centre to restore social functions to streets and squares.
- Provide the appropriate width of the pavement, including convenient conditions for stopping and resting, especially important in the context of older people, children and people with reduced mobility.
- Ensure space continuity and reduce spatial barriers and hazardous locations.
- Eliminate parking on pavements, thus reclaiming space for pedestrians.

- Introduce traffic calming in the centre area – c¬ombine policy solutions, such as a speed limit of 30 km/h or the introduction of equivalent intersections, with engineering solutions – r¬oad narrowing, speed bumps or chicanes.
- Develop the bicycle infrastructure.
- Integrate public transport systems.
- Adapt the accessibility of public transport to the needs of elderly and disabled people.
- Give priority to public transport in road traffic.
- Introduce parking fees as an instrument to ensure the rotation of parking spaces in the town centre.
- Maintain or reduce the number of parking spaces while eliminating illegal parking.

7 CONCLUSION

Transport not only influences climate change but also introduces inequalities between the different users of the city. The privileging of cars, which takes advantage of their appropriation of space, leads to restricting the freedom of movement of other users.

In particular, much more attention should be paid to a more equitable distribution of space in the centre, emphasising soft transport - pedestrian and bicycle. A significant part of the transport area could be successfully recovered and used for other purposes, such as infrastructure for walking and cycling. The lack of an appropriate setting in the form of small architecture or greenery and appropriate pedestrian and bicycle infrastructure translates into unfavourable conditions for other than cars modes of transport.

In this case, providing safe, affordable, accessible and sustainable transport systems for all has not been achieved yet. It would not be possible without changing the way of thinking about transport and introducing solutions for improving the situation of pedestrians, cyclists and public transport.

1 ABSTRACT

Infrastructure projects pose complex management challenges and require comprehensive solutions for diverse needs, including the monitoring of purpose-built nature-based components at regional scale. Our paper demonstrates the capability of spatial imagery in monitoring the health of a micro-hydro renewable energy generation plant in the mountainous region on the outskirts of Kathmandu, Nepal.

Our modelled results utilising the Normalised Difference Water Index (NDWI) from the longitudinal satellite data between between 1988-2020 show the spatial profiles of the hotspots for potential nature-based infrastructure interventions. This is typically an administrative challenge for wider implementation of such interventions in low/middle income countries such as Nepal. We recommend policy measures for enhancing nature-based local livelihoods can be one way for encouraging community-based local management of such initiatives. We also identify the need for regular data updation vital for providing ground-truthed decision making capability for such integrated infrastructures using an Artificial Intelligence platform.

Keywords: energy, spatial analysis, nature-based, infrastructure, monitoring

2 INTRODUCTION

Nepal's new Federal Constitution is creating higher, inclusive economic growth for the population of circa 31million. Increasing level of infrastructure projects are being proposed integrating blue-green (natural) alongside grey (built structures) components to increase sustainability across key sectors, including transport, energy, adventure sports and inner-city (aka "forest city") developments. The last decade has seen a push for integrated infrastructure projects in Nepal, combining nature-based components alongside built structures to meet the sustainable development (SDG 9 - Build resilient infrastructure). Typical projects include transport corridors, alternative energy installations, adventure sports facilities, etc., both in remote, naturally sensitive locations and in the urban hinterlands. However, there is still a lack of a comprehensive project management framework for ensuring effective delivery and post-delivery long-term monitoring of such nature-based engineering projects. Our study presents a case study demonstrating the role of remotely sensed satellite data in optimising infrastructure sustainability through targeted integration of purpose-built nature-based components at a hydroelectricty generation plant in Nepal.

3 METHODOLOGY

3.1 Case study description

The Kulekhani hydropower project (KHP-1) is a rock-fill dam on the Kulekhani River (also known as Indrasarobar), which was constructed in 1977; a 60 MW hydroelectric power station was later installed at the site in 1982. It is situated in the Bagmati River Basin of Makwanpur district of Nepal (between 27° 35′ 07″ N and 27° 37′ 43″ N latitudes; 85° 8′ 17″ E and 85° 9′ 56″ E longitudes) at an altitude of 1430 metres above sea level (Figure 1). The dam area is 7 km long and 114 m deep, with a total storage capacity of approx. 85 million m3 - 12 million m3 allocated to dead storage and 73 million m3 to live storage (Shrestha et al. 2014, Shrestha et al. 2021). This watershed extends from sub-tropical to temperate climate zone and has been facing the severe impact of climate change in the recent decades; daily precipitation level has decreased and temperature has increased in the past 30 years (Ghimire et al. 2019). The neighbouring region comprises of forested and cultivation areas which are aggressively being replaced by urban built-up areas,

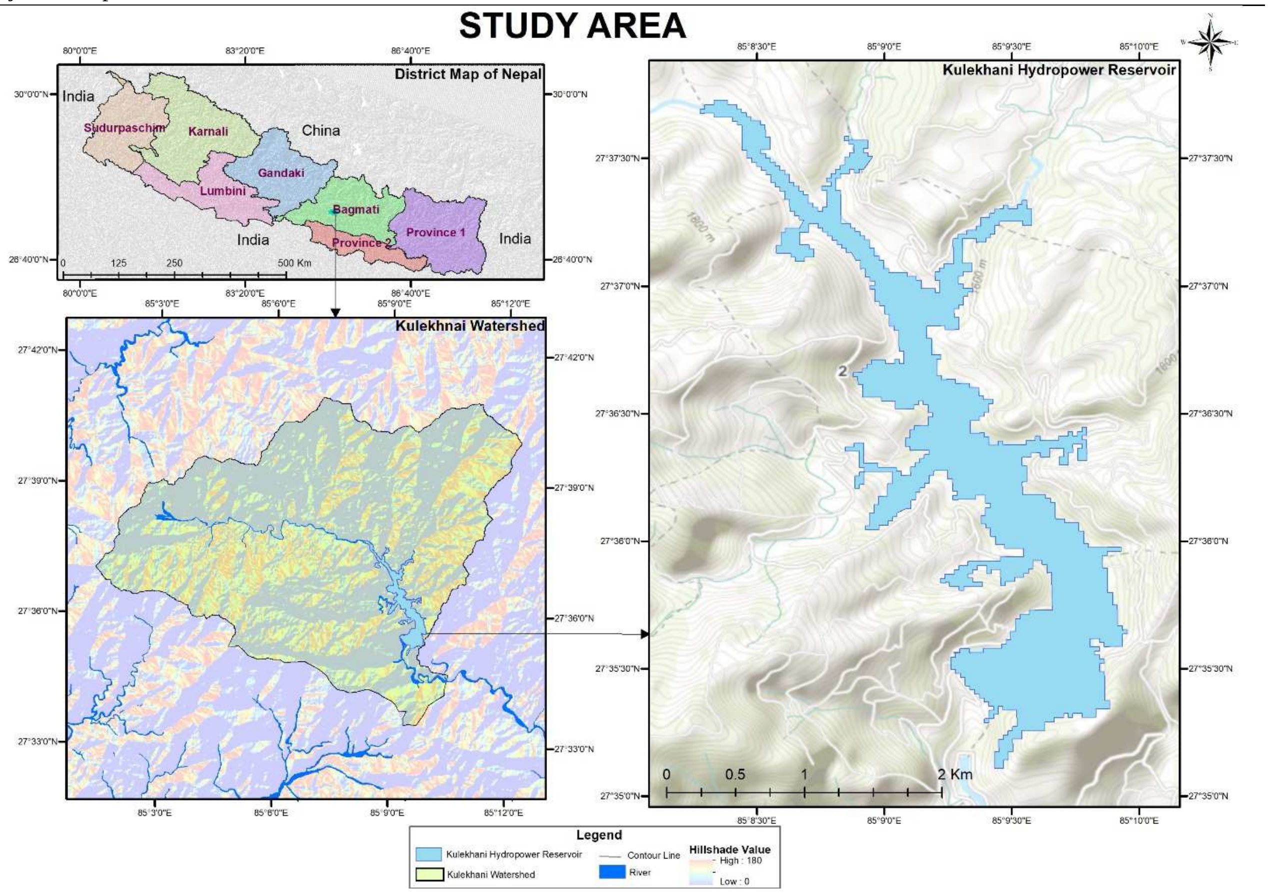

Figure 1: Location map of the study area (the span of the dam area shown in the inset in the right panel).

3.2 Data acquisition

In this study we have collected freely available Landsat Level 2 images 1988-2020 (Landsat 5 Thematic Mapper, TM; Landsat 7 Enhanced Thematic Mapper Plus, ETM+; Landsat 8 Operational Land Imager, OLI) from the United States Geological Survey (USGS), Table 1. All images were verified and analysis was conducted in ENVI v5.3 environment.

Year	1988	1990	1992	1994	1996	1998	2000	2002	2004	2006	2008	2010	2014	2016	2018	2020
Months	29-Nov	4-Feb	23-Oct	13-Oct	18-Oct	8-Oct	22-Nov	27-Oct	9-Nov	30-Oct	20-Nov	25-Oct	23-Dec	25-Oct	31-Oct	22-Jan

Table 1: Time series Landsat 5, 7 and 8 imagery applied (Path/Row 142/040).

3.3 Evaluation of Kulekhani Dam area

We evaluated the water content and its further reduction/expansion in the dam area between 1988 and 2020 utilising the Normalised Difference Water Index (NDWI) from satellite images following the literature (Zhao et al. 2018, Acharya et al. 2019, Zhang et al. 2019, Li et al. 2020). The positive NDWI threshold value of 0 to 1 were applied for the extraction of the water value for all the years (Zhang et al. 2019, Yan et al. 2020). For the extraction of water value the following equations were applied (McFeeters 1996).

$$NDWI^{OLI} = \frac{Green\ (Band\ 3) - NIR\ (Band\ 5)}{Green\ (Band\ 3) + NIR\ (Band\ 5)} \quad \text{Equation 1}$$

$$NDWI^{TM}\ \&\ NDWI^{ETM+} = \frac{Green\ (Band\ 2) - NIR\ (Band\ 4)}{Green\ (Band\ 2) + NIR\ (Band 4)} \quad \text{Equation 2}$$

RESULT

The NDWI estimates were used as the proxy for surface water level of the Dam area. Based on the results, the surface water of Kulekhani dam appears to have expanded significantly over the assessment period, represented by the NDWIs respectively of 0.182 in 1988 and 0.405 in 2020 (Figure 2). In the early part (1990-1994), the NDWI values remained low, however they have increased rapidly beyond 1994, indicating incremental part of the submerged area due to the dam.

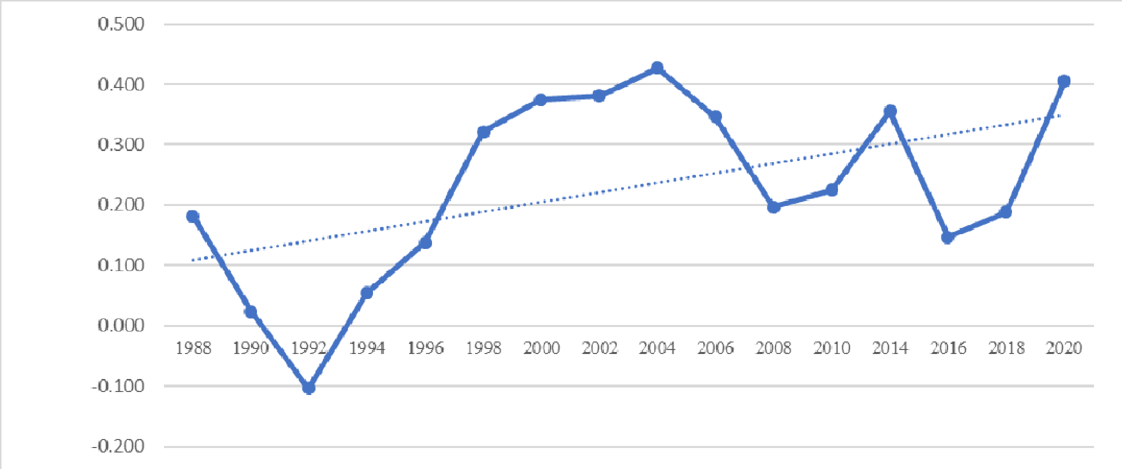

Figure 2. Time-series graph for the NDWI mean pixel values from 1988-2020.

The spatial distribution of the colour-coded NDWI values in the Dam area are plotted in Figure 3, clearly showing the increase in NDWI within the immediate reservoir boundary between 1988-2020. However, the NDWI in the neighbourhood areas of the dam in the corresponding years have been reducing. This could be attributed to multiple factors, such as - climate change impact, variance of precipitation, earthquake, sediment deposition.

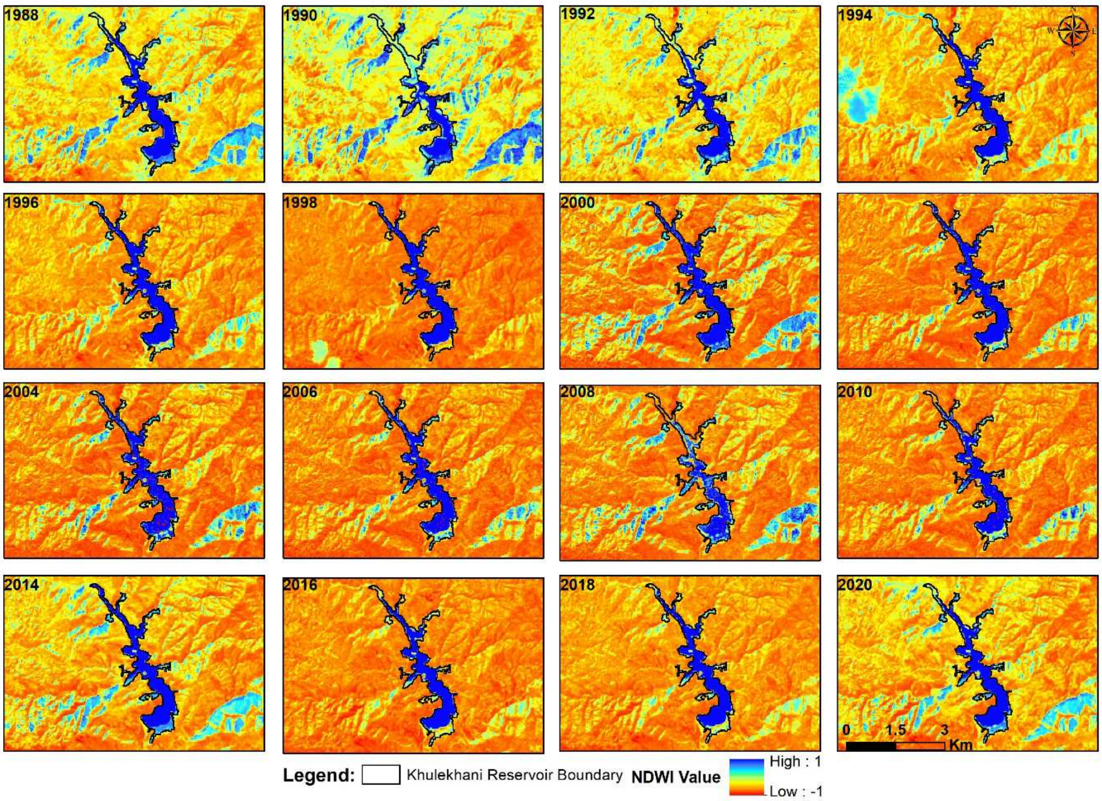

Figure 3: Contour maps of the NDWI profiles showing the reservoir and the neighbourhood areas between 1988 and 2020

4 DISCUSSION AND CONCLUSION

Our study reveals an interesting paradox in relation to the state of hydroelectric power station in mountainous regions - we estimated surface water level of the dam area in the specific case study location increased between 1988 and 2020 (an increase of 122% in the corresponding NDWI values within the reservoir boundary, estimated from satellite imagery from 0.182 to 0. 405). On contrary, the storage capacity

ISBN 978-3-9504945-0-1. Editors: M. SCHRENK, V. V: POPOVICH, P. ZEILE, P. ELISEI, C.BEYER, J. RYSER, G. STÖGLEHNER

of Kulekhani reservoir is reported to be reduced from 85 million m3 to 60 million m3 within the last 30 years (Hurford et al. 2014). Although we did not consider the reasons for this contradictory phenomenon within the scope of this study, previous studies have identified sedimentation deposition as one of the key factors leading to this paradox (Shrestha et al. 2014, Ghimire et al. 2019). Adverse anthropogenic encroachment activities have led to further deterioration of the reservoir storage capacity, with increased level of deforestation leading to gully erosion. We consider longitudinal satellite data as a vital tool in monitoring the overall role of nature-based intervention in mitigating such adverse impacts of reservoir capacity. Going forward, we recommend long-term monitoring using remotely sensed satellite data combined with artificial intelligence as essential for understanding the true scale of sediment collection and the potential role of nature-based intervention in mitigating such adverse impacts for infrastructure projects in hard-to-reach mountainous regions.

Nachhaltige urbane Gewerbeflächen – ein internationaler Vergleich

Sarah C. Schreiner

(Dr.-Ing. Sarah C. Schreiner, Urban Research and Development, Margaretenstraße 39, D-20357 Hamburg, dr.ing.schreiner@gmx.de)

1 ABSTRACT

Seit Beginn der Pandemie im Frühjahr 2020 rücken innerstädtische Gewerbeflächen wieder stärker in den Fokus von Stadtplanerinnen, Stadtplanern, City-Managerinnen und City-Managern. Die Aufenthaltsfunktionen von Stadtzentren wandeln sich. Durch eingeschränkte Nutzungsmöglichkeiten und verändertes Mobilitätsverhalten werden die räumlichen Qualitäten des lokalen Einzelhandels, der großen Bürogebäude, der Gastronomie, des Entertainments und der Kultur infrage gestellt.

Urbane Gewerbeflächen sind elementarer Teil städtischer Nutzungsmischung, da sie vielfältige Nutzungen zulassen und wohnortnahe Arbeitsmöglichkeiten bieten. Bereits vor der Pandemie haben sie sich als resilient gegenüber Veränderungen der Arbeit und der Flächenansprüche durch Internationalisierung und Technologisierung erwiesen. Von daher profitiert in der derzeitigen Situation, neben dem Online-Handel, vielerorts auch die Quartiers-Ökonomie.

Aktuell werden neue Konzepte für das Management des strukturellen Wandels von Innenstädten diskutiert. Für die planerische Transformation von Gewerbe in urbanen Lagen sind bereits einige internationale Beispiele vorhanden. Daher lohnt es sich, einen Blick auf existierende Erfolgsfaktoren zu werfen und für die gegenwärtige Situation zu nutzen.

Anhand von drei Fallbeispielen aus den Niederlanden, Deutschland und Großbritannien beschreibt der Artikel unterschiedliche Steuerungsansätze zur Entwicklung und Umnutzung urbaner Industrie- und Gewerbeflächen sowie deren Effekte auf die lokale Nutzungsmischung.

Im Ergebnis wird deutlich, dass die Stadtverwaltungen in Amsterdam, Berlin und London recht unterschiedlich agieren, um Gewerbe und kleinteilige Nutzungsmischung im Stadtzentrum zu ermöglichen oder zu sichern. Neben prozessualen Formen des kooperativen Umgangs gehören hierzu auch eine flexible Organisation des planungsrechtlichen und immobilienwirtschaftlichen Flächenmanagements.

Keywords: Resilienz, Gewerbeflächen, Quartierstruktur, urbane Produktion, Nutzungsmischung

2 EINLEITUNG: GEWEBE IN DER STADT

Die Frage nach nachhaltigen urbanen Gewerbeflächen hängt eng zusammen mit stadtplanerischen Leitsätzen, bauordnungsrechtlichen Vorgaben sowie städtischen Immobilienrenditen. Die Sicht auf städtisches Gewerbe wandelte sich in den letzten Jahrzehnten. Im Zuge des Strukturwandels der Arbeit und der Internationalisierung veränderte sich auch der Umgang mit Gewerbebetrieben in europäischen Städten grundlegend. Der Artikel beschreibt, wie urbane Gewerbeflächen langfristig und ressourcenschonend genutzt sowie transformiert werden können. Hierfür werden unterschiedliche Steuerungsansätze anhand von drei internationalen Fallbeispielen, die explorativ mittels Ortsbegehungen erhoben wurden, skizziert.

2.1 Wandel von Stadtstrukturen im 20. Jahrhundert

Mit der Charta von Athen (1933) sowie dem Nachkriegs-Leitbild der „gegliederten und aufgelockerten Stadt" entwickelten sich europäische Städte anhand einer funktionsräumlichen Trennung von Arbeiten, Wohnen und Freizeitgestaltung. Industrielle, hafenbezogene und gewerbliche Arbeitsstätten wurden fortan getrennt von Wohnquartieren errichtet, damit Lärm-, Geruchs- und Staub-Emmissionen nicht die Wohnqualität und die Gesundheit der Bevölkerung beeinträchtigen.[1] Diejenigen Stadtbewohnerinnen und Stadtbewohner, die es sich leisten konnten, zogen aus den historischen Stadtzentren an den Rand bzw. in das Umland der Städte. Die „Speckgürtel" und Außen-Stadtteile waren mit Einkaufszentren, Bildungs- und Freizeitangeboten auf die Nahversorgung der neuen Einwohnerinnen und Einwohner ausgelegt. Innenstädte von Großstädten entwickelten sich zu eher monofunktionalen Standorten für unternehmensbezogene Dienstleistungen, großflächigen Einzelhandel, Kultur und Tourismus. Der Ausbau der Verkehrsverbindungen für Pkw, Lkw, Bahn und Schiffe verbesserte die Transportwege für Gewerbebetriebe und unterstützte die Suburbanisierung von Erwerbstätigen.

Im Zuge der Tertiarisierung, Internationalisierung, Automatisierung und Digitalisierung wurden kompakte Stadtquartiere mit kurzen Wegen, ressourcenschonender Infrastruktur und einer kleinteiligen Nutzungsmischung gegen Ende des 20. Jahrhunderts zu attraktiven Wohn- und Büroarbeitsstandorten. Produzierendes oder verarbeitendes Gewerbe verschwand aufgrund von Standortschließungen bzw. Verlagerungen in das außereuropäische Ausland, restriktiven Umweltauflagen oder steigenden Bodenrenditen in vielen Fällen aus den Zentren europäischer Städte. Zurück blieben Flächen, die für andere Nutzungen wie Wohnungsbau, Büro- und Einzelhandel oder Freizeitnutzungen verfügbar wurden.[2]

2.2 Urbanes Gewerbe heute

Urbanes Gewerbe ist heutzutage vielfältig. Es kann unter anderem aus Handwerk, Einzelhandel, Kulturbetrieben, Hafengewerbe, vielfältigen Dienstleistungen und Beherbergungsbetrieben bestehen (siehe Abbildung 1). Diese Unternehmen bieten nicht nur wohnortnahe Arbeits- und Ausbildungsplätze, sondern tragen auch zur kulturellen Integration und sozialem Zusammenhalt der Stadtbevölkerung bei.[3] Die Flächen- und Standortansprüche der Unternehmen variieren je nach Unternehmensgröße, Marktausrichtung, Netzwerkbeziehungen, inhaltlicher Spezialisierung sowie Attraktivität für und Anforderungen an die Arbeitskräfte.

Der allgemein steigende Bedarf nach zeit-effizienter Wohn-Arbeits-Organisation sowie nach Qualitäten von urbanen Stadtquartieren ließ die Grundstückspreise in durchmischten, gut angebundenen Stadtgebieten von Metropolen seit einigen Jahren stark ansteigen. In Wachstumsregionen mit einer großen Flächenkonkurrenz kann das den Druck für eine wirtschaftliche Aufwertung oder einen Funktionswandel innerstädtischer Gewerbeflächen erhöhen[4] Das Das in prosperierenden Städten eher geringe Angebot an verfügbaren Gewerbeflächen lässt standortbezogene Expansionen von eingesessenen Gewerbebetrieben oftmals nicht zu.[5]

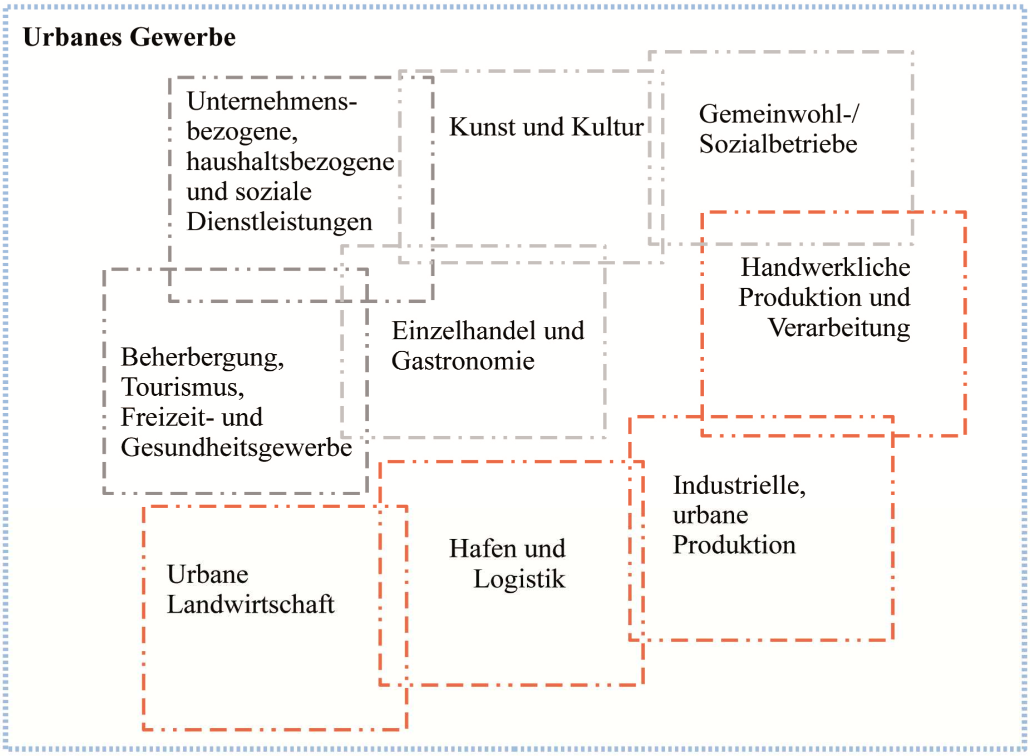

Abbildung 1: Vielfalt und Schnittstellen von urbanem Gewerbe

Bauordnungsrechtliche Vorgaben zum Schutz der Wohnbevölkerung, wie bspw. Lärmschutzauflagen, verstärken den Trend, dass nur noch „störungsarmes" Gewerbe in urbanen Zentren und Mischgebieten

stattfinden kann. Emittierende Unternehmen wie Handwerks- oder Produktionsstätten müssen in Industrie- und Gewerbegebiete, oftmals am Stadtrand gelegen, oder in Gewerbeparks in die Region umziehen.

Innenstädte sind klassische Standorte für Büroflächen, Einzelhandel, Kultur und Gastronomie. Diese Nutzungen sind weniger betroffen von Regulierungen bezüglich Emissionsschutz. Für den Bedarf an Einzelhandelsflächen spielt der Strukturwandel, der durch die Digitalisierung und die Internationalisierung beeinflusst wird (Onlinehandel), eine relevante Rolle.[6] Kultur und Gastronomie sind als publikumsbezogene Angebote vor allem auf attraktive Standorte und gute Anbindung angewiesen.

2.3 Covid-19 als Transformations-Treiber?

Urbane Gewerbeflächenmärkte und Immobilienentwicklungsprojekte für innerstädtische Arbeitsplätze werden im Zuge der Covid-19-Pandemie anders betrachtet.

Die (temporäre) Schließung von Einzelhandel-Filialen, Großraumbüros und Kulturstätten in Innenstädten sowie von inhabergeführtem Einzelhandel, Restaurants, Hotels, Dauerarbeitsplätzen für Dienstleistungen sowie sozialen Einrichtungen in Stadtteilzentren machte drei Aspekte deutlich:[7]

- Die Verlagerung mancher Tätigkeiten ins Homeoffice oder einen Coworking-Space ist abhängig vom Digitalisierungs- und Dienstleistungsgrad (Click and Collect, Remote-Zugänge zu Firmennetzwerken o. ä.) des Unternehmens
- Leerstände oder eine Flexibilisierung von Nutzungszeiten großer Gewerbeflächen ermöglicht die Um- oder Zwischennutzung von Gewerbe-Standorten in Innenstadt-Lagen, bspw. für soziale oder kulturelle Zwecke[8]
- Die Verringerung stationärer Innenstadtflächen bedingt ggf. die Bereitstellung von wohnortnahen Gewerbeflächen bzw. Arbeitsmöglichkeiten.

Offen ist, wie sich solche nun erprobten, fragmentierten Tätigkeiten zukünftig auf die städtischen Gewerbeflächenmärkte auswirken werden. Für den Dienstleistungssektor wird wohl mobiles Arbeiten oder Homeoffice eine größere Rolle spielen. Von einer langfristigen Verringerung innerstädtischer Büroflächennachfrage geht jedoch Colliers International für die großen deutschen Büromarktstandorte derzeit nicht aus.[9] Für produzierende und verarbeitende Unternehmen sowie Gast- und Kulturwirtschaft werden ggf. die Mobilität sowie Wohn-Arbeits-Beziehungen der Beschäftigten eine größere Rolle spielen.

Strategien für eine stärkere Verdichtung innerstädtischer Flächen werden derzeit jedoch in Frage gestellt.[10] Denn der öffentliche Raum, Grün- und Freiflächen haben im Zuge der Pandemie eine neue Aufmerksamkeit erfahren.[11]

3 NACHHALTIGE URBANE GEWERBEFLÄCHENENTWICKLUNG

Viele europäische Kommunen verfolgen für ihre räumlich-städtebauliche Entwicklung das Leitbild einer kompakten Stadt mit funktionaler Diversität, kurzen Wegen sowie ressourcenschonender Infrastruktur und Bodennutzung.[12] Die im Jahr 2020 verabschiedete „Neue Leipzig-Charta" ergänzt diese Ziele, indem sie auf die produktiven und transformativen Kräfte von Stadtquartieren, Städten und Regionen abzielt, um eine integrierte und Gemeinwohl-orientierte Stadtentwicklung zu fokussieren. Nachhaltigkeit soll zum zentralen Handlungsfeld für die Stadtplanung in europäischen Städten werden.[13]

3.1 Steuerungsansätze

Mit den aktuellen Zielen der „produktiven Stadt" und der Förderung von „Ko-Kreation" wird ein nachhaltiges Gewerbeflächenmanagement relevant für die Stadtentwicklung. So sollen Produktion und (Klein-)Gewerbe zwar emissionsarm sein, aber (wieder) mitten in der Stadt stattfinden. Voraussetzung

[6] Vgl. Anders et al. 2021:19

hierfür ist, dass produzierende und verarbeitende Unternehmen innovativ, flexibel und Technologie-basiert agieren. Grundlagen hierfür bilden die Transformations-Effekte der Wissensgesellschaft und der Kreativwirtschaft.[14] Auswirkungen der Digitalisierung auf veränderte Arbeitsorganisation und Flächen-Bedarfe werden nicht nur den urbanen Gewerbeflächenmarkt, sondern auch die innerstädtischen Quartierstrukturen beeinflussen.[15]

Dabei bedienen sich Kommunen verschiedener Steuerungsansätze, die sich auf das städtische Flächenmanagement oder Kooperationen mit privaten Akteuren beziehen:

Eine Umwandlung von Büro- in Wohnflächen wird mit bauordnungsrechtlichen Instrumenten insbesondere in denjenigen Städten unterstützt, die einen Mangel an Wohnraum verzeichnen. Mit der Einführung der Kategorie „Urbanes Gebiet“ in die deutsche Baunutzungsverordnung (2017) wurde außerdem planungsrechtlich eine stärkere Nutzungsmischung in innerstädtischen Lagen ermöglicht.

Mit Agenturen für Leerstandmanagement wird versucht, brach fallende Innenstadtflächen – bspw. Ladenlokale in Fußgängerzonen – für andere Nutzungen wie Kultur, gemeinnützige Initiativen oder Unternehmensgründerinnen und Unternehmensgründer verfügbar zu machen. Dazu werden auch temporäre Nutzungen (Pop-Up-Stores) und kooperative Formen für Büroarbeits- und Werkstatträume (Coworking-Spaces) zugelassen, die gleichzeitig die Umgebung beleben sollen.

Einzelbetriebliche Beratungs- und Kooperationsprogramme können diejenigen Unternehmen unterstützen, die Hilfe bei der Digitalisierung ihrer Wertschöpfungsketten oder bei der Anpassung von Betriebskonzepten benötigen. Diese werden ergänzt durch finanzielle Unterstützungsinstrumente des Bunds und der Länder – bspw. in Form von Krediten der öffentlichen Hand.

3.2 Flächentypen

In Bezug auf urbane Gewerbeflächen zeigt sich, dass kleine, gemischt genutzte Gewerbeflächen und -quartiere tendenziell anpassungsfähiger sind als monofunktionale Flächen.

Aus stadtplanerischer Sicht sind insbesondere die großflächigen Bürostandorte in der City problematisch, aber auch große Handelszentren und Shopping Malls am Innenstadtrand. Denn diese sind bei Krisen bzw. plötzlichen, großen Schwankungen an Kunden, Absatz oder auch Beschäftigten eher von Leerstand betroffen.[16] Ehemalige Großareale von Fabriken, Kasernen oder Infrastruktur (Verkehr, Energie) sind jedoch gut für eine Konversion in gemischte Quartiere geeignet.[17]

Dagegen erweisen sich gemischte Innenstadtquartiere, innerstädtische Gewerbegebiete und kleine Handwerkerhöfe bei guter Selbstorganisation und Vernetzung als ausdauernd – auch in Transformationsprozessen.[18] Sie sind aufgrund ihrer Flächen- und Baustrukturen oftmals gut für Nutzerwechsel geeignet.[19]

Grundsätzlich können folgende Gewerbeflächen-Typen unterschieden werden, die nachhaltig sind, indem sie adaptive und transformative Kapazitäten für Nutzungsänderungen bieten:[20]

Urbane Lage:	City	Cityrand	Innenstadtrand		
Art der Fläche (gem. BauNVO):	Mischgebiet	Urbanes Gebiet	Gewerbegebiet	Industriegebiet	
Art der Immobilie:	Ladengeschäft	Handwerker- und Gewerbehof	Büroplatz/ Coworking-Space	Werkstatt/ ehemalige Produktionsfläche	Büro/Ladenbüro

Tabelle 1: Nachhaltige Gewerbeflächentypen

3.3 Akteure

Inwiefern Gewerbeflächen und -gebiete im urbanen Raum nachhaltig erhalten oder entwickelt werden, hängt maßgeblich von vier Akteursgruppen ab: Den Immobilien-Eigentümerinnen und Immobilien-Eigentümern,
